- 100-YR FLOOD PROTECTION

GENERAL NOTES:

1. THE CARE OF WATER PLAN AND TEMPORARY STRUCTURES SHOWN HERE ARE FOR PERMITTING AND COST ESTIMATION PURPOSES ONLY. THIS CARE OF WATER PLAN IS BASED ON CORRESPONDENCE WITH THE CITY OF GRAND RAPIDS AND THE CONSTRUCTION MANAGER ADVISOR. THE CONTRACTOR WILL ULTIMATELY BE RESPONSIBLE FOR DEVELOPING AND MAINTAINING A CARE OF WATER PLAN TO MEET PERMITTING CONDITIONS AND CONSTRUCTION NEEDS.
2. BRIDGE LOW CHORDS REPRESENT LOW CHORD OF BRIDGE DECKS. GILLETT AND PEARL STREET BRIDGES HAVE ARCHED BAYS; LOW CHORDS SHOWN REPRESENT APPROXIMATE HIGH POINT OF ARCHES. CONTRACTOR IS RESPONSIBLE TO VERIFY LOW-CHORD ELEVATIONS AND CLEARANCE HEIGHTS.
3. ALL IN WATER WORK REQUIRES USE OF APPROVED BMP'S TO PREVENT IMPACTS TO WATER QUALITY.
4. PROTECT IN PLACE WETLANDS AND MATURE TREES NOT SPECIFICALLY DESIGNATED FOR REMOVAL OR IMPACT.
5. BE PREPARED TO UN-ISOLATE WORK AREA AND ALLOW FLOW ON BOTH SIDES OF CHANNEL UPON SHORT NOTICE IF OWNER'S REPRESENTATIVE DETERMINES BED SCOUR NEAR BRIDGE PIERS, FLOODWALLS, OR OTHER INFRASTRUCTURE SHOULD BE INSPECTED.
6. CONTRACTOR SHALL MAINTAIN AND MONITOR ALL EXISTING UTILITY OUTFALLS TO FUNCTION OR DRAIN PROPERLY THROUGHOUT CONSTRUCTION; INCLUDING BOTH MARKED AND UNMARKED UTILITIES.
7. ACCESS CAUSEWAYS, WORK ISOLATION MEASURES, AND TEMPORARY GRADE CONTROLS SHALL BE INSTALLED IN THE FLOWING RIVER. REFER TO THE TECHNICAL SPECIFICATIONS FOR FLOW RATE AND DEPTH INFORMATION. CONTRACTOR SHALL SUBMIT PLAN TO PERFORM WORK IN THE FLOWING RIVER WITH MAXIMUM DEPTHS TO PERFORM WORK.
8. SURFACES FOR ALL TEMPORARY CAUSEWAYS AND COFFERDAMS CAN BE PROVIDED TO CONTRACTOR

CONSTRUCTION SEQUECNING NOTES:

1) CAUSEWAYS MUST BE INSTALLED BEFORE REMOVAL OF DAMS OR CONSTRUCTION OF PROPOSED IMPROVEMENTS CAN BEGIN AT ANY GIVEN LOCATION.
2) PROPOSED IMPROVEMENTS AT DAM 3 SHALL BE HELD UNTIL AFTER COFFERDAM AT DAM 2 HAS BEEN REMOVED.
3) PROPOSED IMPROVEMENTS AT DAM 4 SHALL BE HELD UNTIL AFTER COMPLETION OF PROPOSED IMPROVEMENTS AT DAM 2.

MUSSEL RELOCATION NOTES:

1) MUSSEL RELOCATION IS ANTICIPATED TO OCCUR BY OTHERS, PRIOR TO IN-CHANNEL CONSTRUCTION ACTIVITIES BEGINNING WITH THE EXCEPTION OF NOTE 3 BELOW.
2) LOCATIONS UNABLE TO BE ACCESSED FOR MUSSEL RELOCATION WOULD BE RELOCATED DURING CONSTRUCTION, IF FLOW CONDITIONS ALLOW AND RELOCATION IS ABLE TO BE COMPLETED AHEAD OF CONSTRUCTION ACTIVITIES.
3) THE AREA WITHIN THE WORK ISOLATION AT DAM 2 WOULD BE RELOCATED PRIOR TO WORK COMMENCING IN THAT AREA. RELOCATION ACTIVITIES HERE WOULD HAVE UP TO 10 DAYS TO CLEAR THE AREA.

THE UNDERGROUND LOCATIONS SHOWN FOR BEDROCK, NATURAL GAS (GAS), TELEPHONE (TEL), ELECTRICAL POWER (PWR), CABLE TV (CTV) AND FIBER OPTIC LINES (FIBER) ARE APPROXIMATE. THE CITY OF GRAND RAPIDS ASSUMES NO RESPONSIBILITY FOR THEIR ACCURATE REPRESENTATION IN THIS DRAWING. MISS DIG MUST BE CONTACTED PRIOR TO CONSTRUCTION TO LOCATE THESE UTILITIES.

1.0 INTRODUCTION

The City of Grand Rapids (City) submitted an application for permits under Parts 301, 303, and 31 of Michigan's Natural Resources and Environmental Protection Act (NREPA) to the Michigan Department of Environment, Great Lakes, and Energy (EGLE) to construct the Grand River Revitalization Lower Reach Project (Project) on October 30, 2020 (JPA-HNV-A018-7X9N3). After receiving and responding to three correction requests from EGLE dated November 30, 2020 and February 9, 2021, and June 1, 2022, the City submitted revised materials in support of its permit application on June 25, 2021, including a revised Basis of Design report.

EGLE deemed the permit application administratively complete on August 22, 2022, and placed on public notice between September 15 and October 5, 2022. A public hearing was held virtually on September 29, 2022. A letter or remaining issues was sent to the City by EGLE on November 4, 2022, outlining remaining issues that needed additional conversation and discussion. On December 14, 2022, the United States Environmental Protection Agency Region 5 issued an official objection letter to the City's permit application. After further discussion and conversations with regulatory agencies, the City of Grand Rapids withdrew permit application HNV-A018-7X9N3 on March 9, 2023.

On March 16, 2023, the City and GRWW met with MDNR, EGLE, USFWS, and EPA staff at an in-person meeting in Lansing, MI to develop a new framework to guide the project redesign efforts that are now the subject of a new permit application and this Basis of Design document. It was through this framework, which included EGLE and MDNR as collaborative partners in the design of the new Project, a preferred alternative was developed to meet shared goals and constraints, which were also agreed on between the City, GRWW, EGLE, and MDNR through the re-design process.

The City of Grand Rapids (City) submits this Basis of Design report to EGLE in support of the application submitted by the City for permits under Parts 301, 303, and 31 of Michigan's Natural Resources and Environmental Protection Act (NREPA) to construct the re-designed Grand River Revitalization Lower Reach Project (Project). This Report is intended to provide background information related to the Project, including the purpose of the Project and the many design alternatives that were considered before deciding to pursue the Project. It also describes the Project's impacts on regulated resources and analyzes alternatives to those impacts in accordance with Parts 301 and 303 of NREPA.

This Report first provides an overview of the Project and discusses the Project purpose (see Section 1.3). Next, the Report discusses the reasons the Project is being proposed by the City, including the existing conditions that the Project seeks to improve (see Section 2.0), the collaborative redesign process and shared goals and constraints (see Sections 3.0), and the various alternatives and redesign concepts considered (Section 4.0). The Report then provides a summary of the Project's design (see Section 5.0) and discusses the construction methodology that will be employed (see Section 6.0).

1.1 PROJECT LOCATION

The overall extents of the Project are shown in Figure 1 and Figure 2. The Project is located just above low-head dam # 4, upstream of Bridge Street to Fulton Street on the Grand River in downtown Grand Rapids, Michigan. The Grand River Watershed is the second largest in the State of Michigan with an overall drainage area of 5,572 square miles and an elevation change of approximately 680 feet over about 250 river miles. The upstream drainage for the project location (low-head dam 4 upstream of Bridge Street) is approximately 4,900 square miles. The latitude and longitude of the upstream and downstream extents of the project along the centerline of the river are as follows:

Upstream Extent:
42.97082° N ; -85.67480° W
Downstream Extent:
42.96339° N ; -85.67606° W

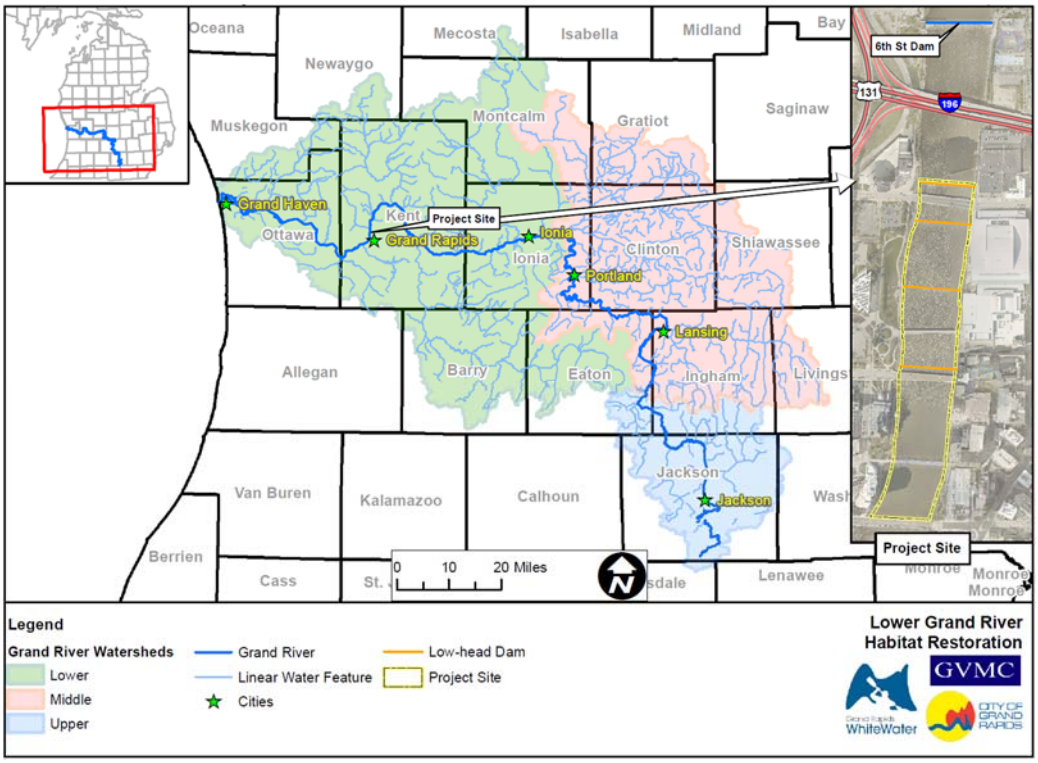

Figure 1: Project Location Map

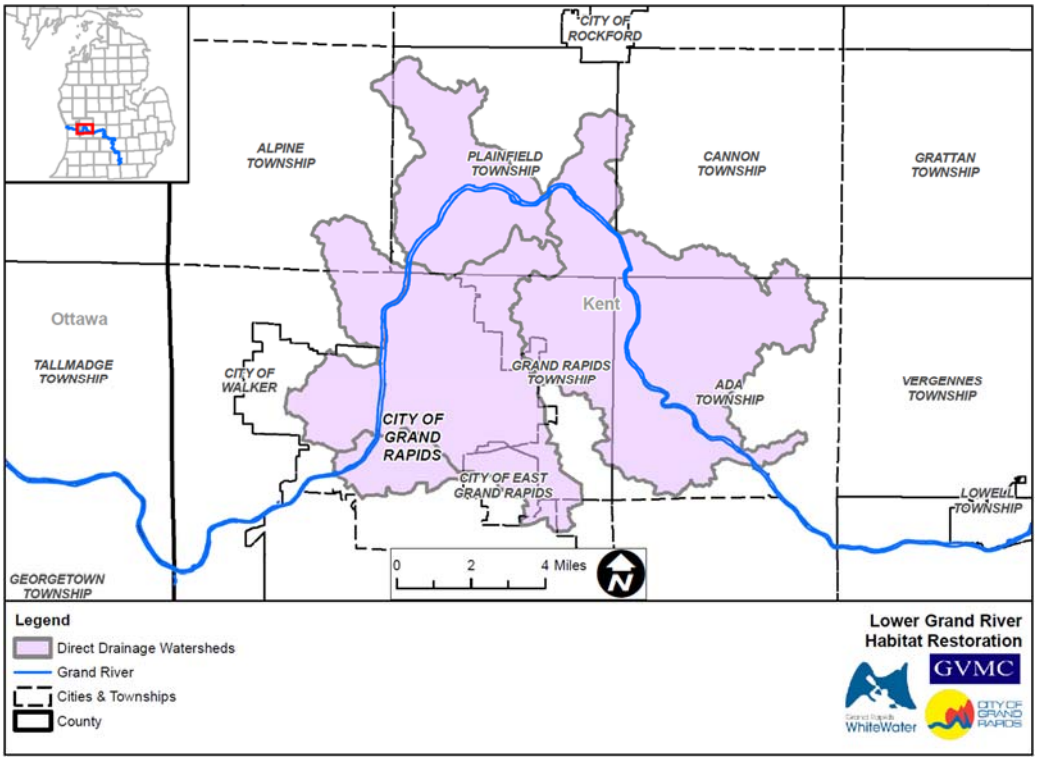

Figure 2: Project Watershed Boundary

The location of the proposed Project is within the most urbanized reach of the Grand River where rapids historically existed within the City of Grand Rapids, Michigan. Between Lake Michigan and Ada, Michigan (a distance of approximately 60 river miles) river gradient steep enough to restore rapid habitat only exists at the project reach. The geographical extent of the Project was identified to maximize restoration potential of bed forms similar to the historic rapids and aquatic habitat for native fish and mussels.

1.2 PROJECT OVERVIEW

The need for the Project arises from the degraded condition of the river, which is an important natural resource for Grand Rapids and the State of Michigan, and several recognized safety problems associated with that degraded condition. Historic physical changes made to the Grand River as it flows through downtown Grand Rapids, including construction of four low-head dams and removal of natural substrate, have impacted native and listed species of fish and mussels, limited public recreational activities, and altered habitat. Studies have concluded that the productivity of fish and mussel communities in the Project area and surrounding portions of the Grand River are currently much lower than what is possible. For example, Hanshue and Harrington (2017) indicate that the low-head dams in the Project area "likely represents a barrier to native fish species (e.g., walleye [*Sander vitreus*], suckers [Family Catostomidae]) during low flow conditions," and the authors go on to state that "Prior to their destruction, the rapids provided substantial rocky spawning habitat for several Lake Michigan species, including cisco [*Coregonus artedi*], lake whitefish [*Coregonus clupeaformis*], lake trout [*Salvelinus namaycush*], and lake sturgeon [*Acipenser fulvescens*]. Although lake-run populations of cisco, lake whitefish and lake trout are no longer extant, restoring the rapids in Grand Rapids would greatly benefit lake sturgeon recovery efforts (Hay-Chmielewski and Whelan 1997, Aadland 2010)." Furthermore, the low-head dams in the Project area have been identified as "One of the largest impediments to the current fish community." Fish Passage Report (Encompass, 2020). The Grand River continues to be a critical river in that it could support lake sturgeon recovery efforts in the Lake Michigan Basin. According to *Lake Sturgeon* Michigan's Lake Sturgeon Rehabilitation Strategy, the Grand River sturgeon population is small and declining yet one of only four believed to be above the Minimum Viable Population Size and where succesful reproduction still occurs (Hayes and Caroffino 2012). The availability of spawning and staging habitats in rivers is considered a major factor limiting the recovery of lake sturgeon in Lake Michigan (Daugherty et. al, 2009, Auer 1999)." The Project would improve sturgeon access, as well as staging and spawning habitat, within the Project area, and would remove barriers to potential future upstream restoration efforts.

Past development has significantly reduced the diversity of aquatic habitat in the river. Along the reach of the river that courses through downtown Grand Rapids, the Grand River drops 18 feet, representing the steepest gradient anywhere along its entire length. Only a small percent of river habitat in the lower peninsula of Michigan is comprised of rapid-type habitat, which is important to the life cycle of many aquatic species. Rapid-type habitat is defined as a river system with a steep energy gradient, coarse bed substrates, and non-uniform distribution of instream velocities. Historic physical alterations to the Grand River have eliminated this habitat from the Project area, affecting fish and mussel communities and limiting public recreational opportunities. In particular, the four low-head dams have altered sediment transport, flow velocity, fish passage, and substrate suitability and have resulted in public safety hazards, leading to multiple deaths. The dams have resulted in significantly reduced habitat diversity; in addition, fish and mussel community diversity and productivity are currently lower than pre-development conditions (Hanshue and Harrington 2017). During five years of sampling in the downtown reach of the Grand River, the most abundant fish family captured was Sunfish. The two most abundant

species were bluegill and mimic shiner, both of which are associated with sedentary and tranquil waters and not rapid habitat that once dominated the area (Encompass, 2023).

The City proposes to make improvements in and along the Grand River within City boundaries to restore the rapids in the lower reach of the river to improve public safety, restore aquatic habitat diversity and suitability for native Great Lakes fish and mussel species, and enhance river access and use.

1.3 PROJECT PURPOSE

The purpose of the project is to Restore the rapids, improve public safety, restore aquatic habitat diversity and suitability for native Great lakes fish and mussel species and enhance river access and use.

-- END OF SECTION 1 –

2.0 EXISTING CONDITIONS

The Project reach is in downtown Grand Rapids, MI, in one of the most heavily modified and urban stretches of the Grand River. The reach has been dredged, filled, walled, and dammed during the last 150 years. The river is encroached by fill and concrete flood walls on the east bank. On the west side, the bank is a riprapped slope with some vegetation. Numerous bridges cross the river and the majority of the bridges have three to five piers within the channel. An oblique aerial image of the project reach with a southerly, down-river view is shown in Figure 3. Refer to Figure 6 for a location map of each low-head dam.

The Project reach is the downstream part of a uniquely steep-gradient stretch of river through downtown Grand Rapids. The downtown stretch of the Grand River is unique compared to the upstream and downstream reaches, in both profile and planform. The steep grade of the river through downtown Grand Rapids, as well as exposed bedrock in the channel, formed the old rapids. Transport of logs from upstream over shallow rapids and the development of downtown Grand Rapids created the need for the construction of the 6th Street Dam and the four low-head dams. The river drops approximately 18 feet of water surface elevation throughout the two miles of channel centered in downtown Grand Rapids, which is over 10 times steeper through this stretch of river as compared to the channel grade upstream or downstream.

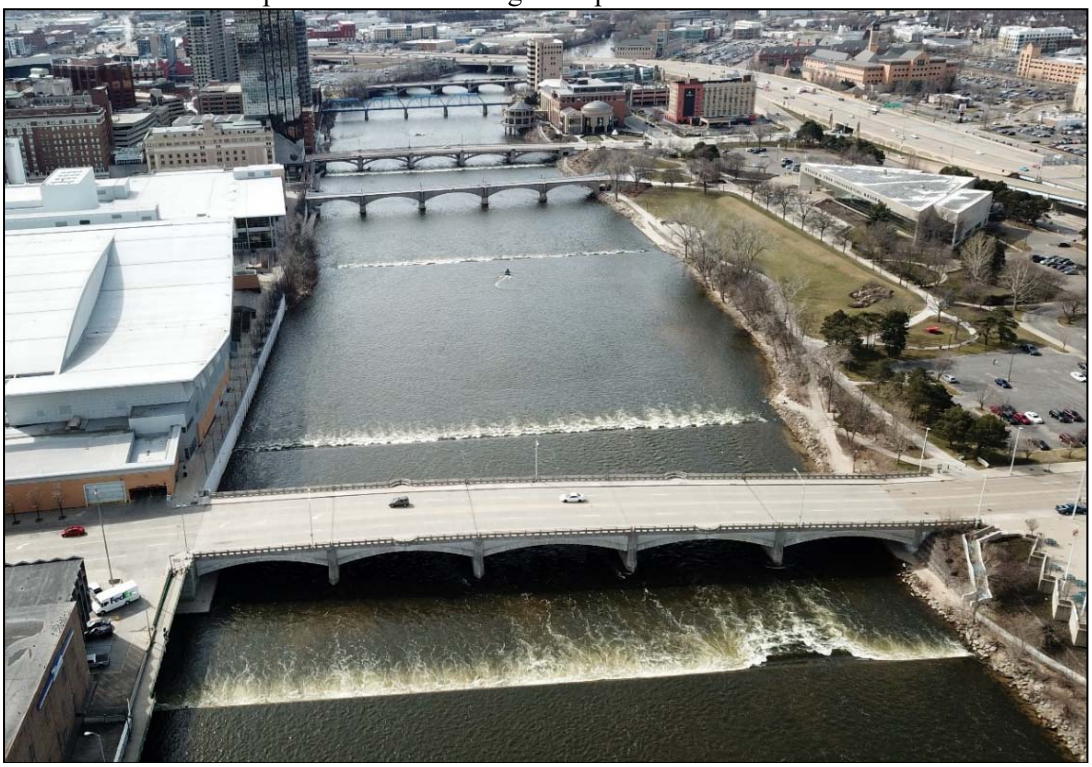

Figure 3: Project reach, with low-head dam #4 and Bridge Street at bottom of photo

2.1 RIVER DIMENSIONS, PATTERN, PROFILE

The Project reach extends from the upstream face of Fulton Street Bridge to 300 feet upstream of the Bridge Street Bridge. The project reach is slightly over a half mile long, through which the Grand River flows from north to south. The river is very straight through the project reach with a sinuosity of 1.0. The channel is laterally confined on both sides by concrete floodwalls on the east and riprap-lined banks with some vegetation on the west. At some locations on the west bank, the 100-year flood protection berms extend laterally away from the channel to allow for isolated upland areas to be inundated by more regular flood flows. In general, the floodwalls and berms function to keep the Grand River disconnected from the floodplain, which has been filled and

heavily developed on both sides. At bankfull, the average channel width is approximately 470 feet and does not vary much from the average through the project reach. The filled floodplain, vertical floodwalls and steep riprap banks in the project minimize expansion of the wetted area during high flow events, so the channel width remains relatively consistent through the annual hydrograph as well. Table 1 shows the average channel width at a range of flows. The determination of the bankfull flowrate is discussed in Section 2.5.

Table 1: Average Channel Width in Project Reach

Flow (cfs)	Average Channel Width in Project area (ft)	Percent of Bankfull average channel width
890	446	95%
5,000	455	97%
10,000 (OHW)	464	99%
13,000 (Bankfull)	470	--
33,000 (10-year)	510	109%
55,000 (100-yr)	565	120%

The average riverbed drops approximately 7.5 feet through the project reach, with the majority of this drop occurring at the four low-head dams. The average channel slope is 0.003 ft/ft. The average channel slope between the dams is 0.0014 ft/ft. A profile of the project under existing conditions is shown in Figure 4.

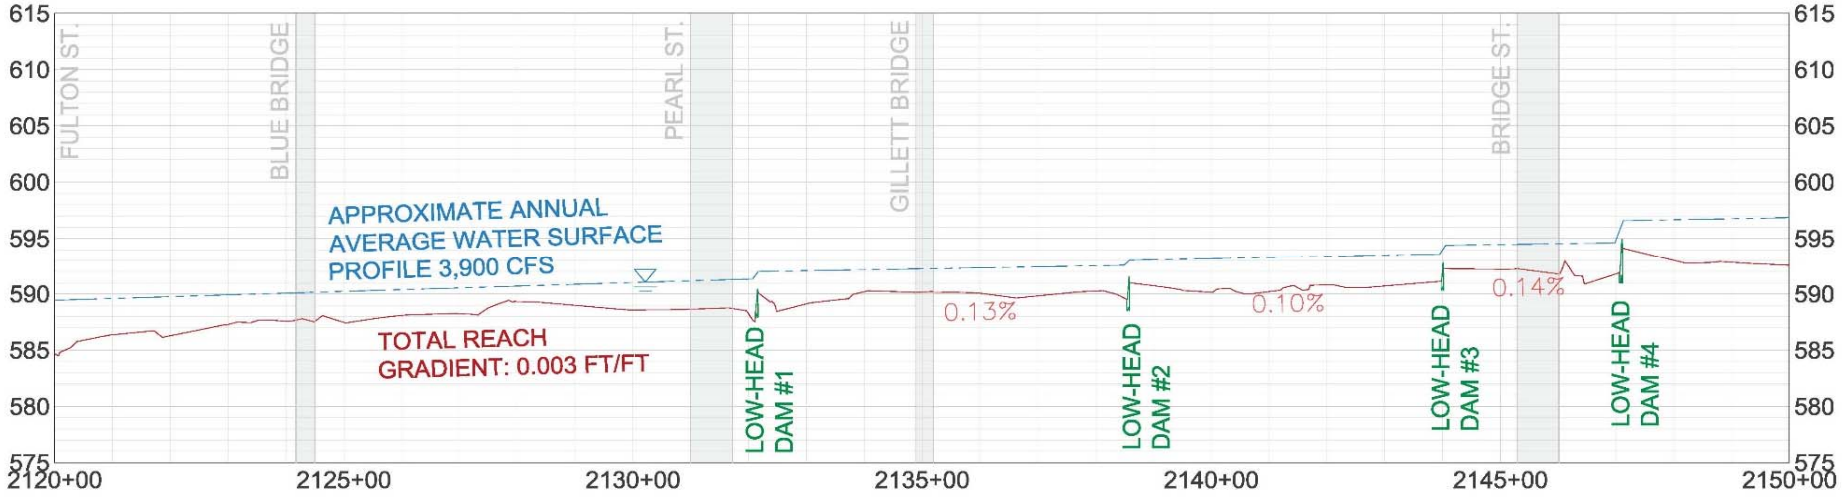

Figure 4: Project Reach Channel Slope

2.2 EXISTING LOW-HEAD DAMS

The existing channel condition has been established through the creation of uniform hydraulics, created by the installation of connectivity-disrupting low-head dams. Significant dredging and mining of large substrate from the channel has also occurred within the Project reach. Figure 5 shows some of this work occurring in the early 1900s.

Figure 5 - Workers removing large substrate from the channel in the early 1900s

The 6th Street Dam is directly upstream of the Project limits. It was originally constructed over 150 years ago in order to facilitate the floating of logs from upstream over the bedrock outcrop on river left. The most recent known maintenance to the dam was 94 years ago in 1929.

There are four channel-spanning low-head dams in the project reach which function to expand and provide uniformity to the width of the channel, help distribute the water surface gradient of the reach, and provide grade control. The low-head dams have between 0.5 and 2 feet of headloss and become submerged by tailwater as flows increase; all four dams are submerged by the bankfull flow of 13,000 cfs.

The four low-head dams were originally constructed in the 1920's as "beautification dams" and were intended to maintain uniform hydraulics and inundation limits to keep sewage from accumulating on the shoreline. The original purpose of these dams is no longer relevant in the context of healthy river ecology, and raw sewage is no longer discharged to the river from the City of Grand Rapids. The dams were constructed of concrete with an ogee-crested shape. Each is approximately 450-feet wide, extending from the floodwall on the east bank to the west bank. The structural height of the dams varies from 1.5-feet to 3-feet and all have a footer that is at least 1-foot thick.

The existing dams impact the ability of fish and other aquatic organisms to thrive, limit fish passage, and prohibit safe recreational uses of the river. The dams pose considerable safety hazards due to the circulating hydraulics downstream of the dams. The reach is rarely used for downstream boating due to this reason. The dams also present an upstream navigation hazard for watercrafts and upstream passage is only possible during flow rates greater than approximately

5,000 cfs when tailwaters have submerged most of the dams. The dams have also deteriorated over the years and show signs of fracturing and toe scour. Approximately 65 feet of Dam #4, just upstream of Bridge Street, has partially collapsed and a significant change in hydraulics is visible 115 feet west of the river centerline at nearly all flow rates. The locations of the four low-head dams are identified in Figure 6. Table 2 summarizes the characteristics of the four structures.

Table 2: Low-head dam descriptions

Low-head Dam #	Location	**Height (ft)** ***(Crest to Top of Footer)***	**Crest Elev. (ft)**	**Bottom of Footer Elev. (ft)**
1	Upstream Pearl St	1.5	590.5	588.0
2	Upstream Gillett Pedestrian Bridge	2.0	591.5	588.5
3	Downstream of Bridge St	1.5	592.8	590.0
4	Upstream of Bridge Street	3.0	595.0	591

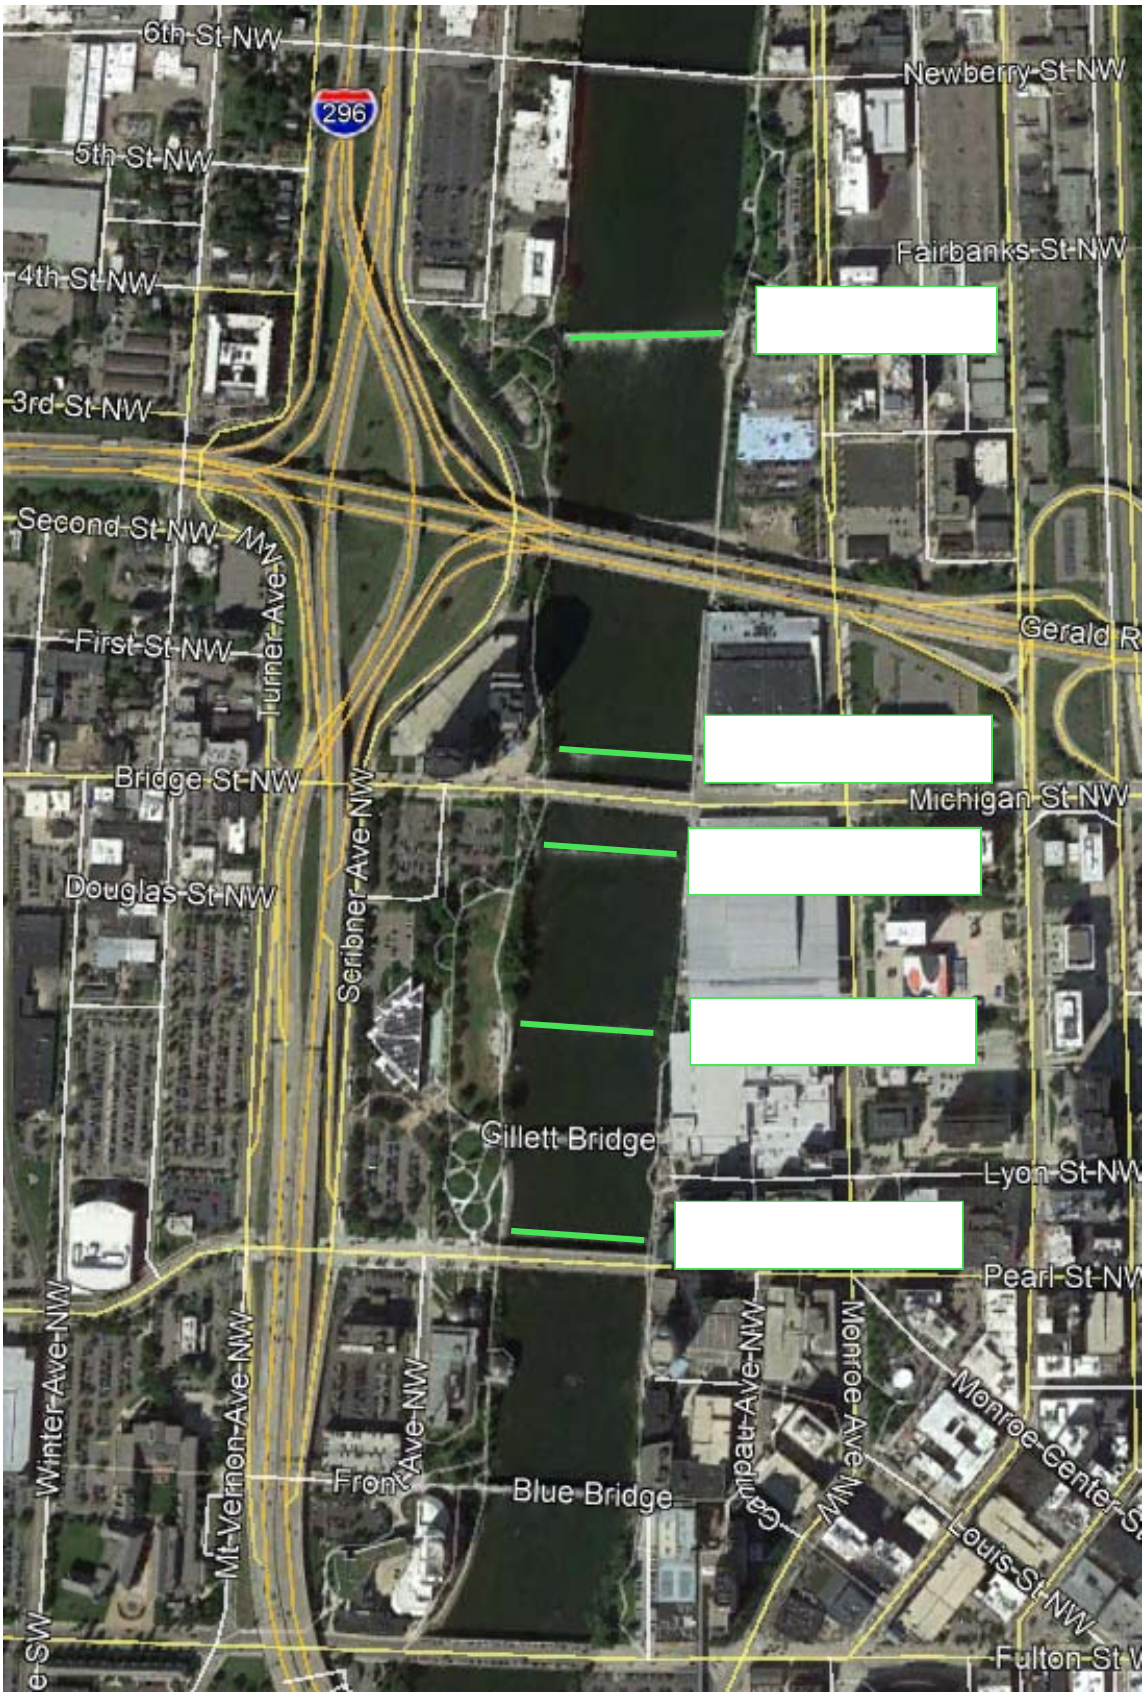

Figure 6: Low-head Dam Location Map (Google Earth)

Figure 7: Low-head dams #4 (upstream) and #3 (downstream) in vicinity of Bridge Street, Low-head dams #2 and #1 are similar in size and headloss to dam #3. Note the failed portion of dam #4 if the upper left corner of this photo.

2.3 DISCHARGE

Per EGLE guidance, harmful interference and flood risk were evaluated based on the flowrates shown in Table 3. These flow rates were determined through correspondence with EGLE (refer to Attachment 2 of TOC No. 5 Hydraulics Report). These flow rates were used in all model runs. The project does not change the hydrology of the Grand River through the project reach or downstream.

Table 3: EGLE Flood Flow Rates

Recurrence Interval	Flow (cfs)
100-yr	50,000
50-yr	44,000
25-yr	38,000
10-yr	31,000
5-yr	26,000
2-yr	18,000

More regular flows which occur throughout a typical summer and fall were used to evaluate suitable aquatic habitat, fish passage, substrate stability, and recreational hydraulics. Flowrates used to evaluate these design elements ranged from the 7Q10 low flow of 890 cfs up to the bankfull flowrate of 13,000 cfs.

Potential impacts to the effectiveness of 6th Street Dam as a barrier to sea lamprey escapement was evaluated by comparing modeled tailwater elevations at 6th Street Dam. Under existing conditions, tailwater elevations completely submerge the crest of the dam during 27,000 cfs and the 6th Street Dam fails meets criteria used by GLFC for restricting upstream migration of sea lamprey. Refer to TOC No. 8 Hydraulic Influence at 6th Street Dam for more information.

2.4 FEMA MAPPED FLOOD ZONES AND ELEVATIONS

The project is located in a detailed study area of the Grand River as described in the FEMA Flood Insurance Study (FIS) (FEMA, 2023). Per FEMA, the project reach is within a flood insurance zone of AE, which specifies that special flood hazard areas are inundated by the 100-year flood, and base flood elevations have been determined by detailed methods. FEMA Flood Insurance Rate Map (FIRM) FIS water surface profiles are presented in in Attachment 5 of TOC No. 5 Hydraulics Report.

2.5 BANKFULL CHANNEL DIMENSIONS AND ELEVATIONS

Due to the large degree of modifications to the river that have been made in the lower project reach (including dredging of the channel bed and construction of dams, floodwalls, and berms), bankfull flow rate is difficult to identify. The floodwalls and berms restrict the river from naturally interacting with the floodplain and dams cause unnatural changes in water levels. Furthermore, the flat tailwater downstream of the project reach causes submergence of the downstream end of the reach at lower flow rates than further upstream.

Reliable bankfull indicators do not exist within the project reach due to the presence of floodwalls and berms. Therefore, indicators of bankfull flow were evaluated upstream of the project reach near Riverside Park. Changes in vegetation and bank slope along the banks of Riverside Park were identified and surveyed. See Figure 8 for a depiction of an example where bankfull indicators were observed near Riverside Park. These elevations were correlated to a flowrate of 10,000 cfs using calibrated hydraulic models. However, due to the influence of 6th Street Dam, this is likely a low estimate of bankfull flow.

According to the National Oceanic and Atmospheric Administration (NOAA), bankfull flow upstream and downstream of the project reach is 13,000 cfs based on the USGS gage in downtown Grand rapids (https://waterdata.usgs.gov/nwis/uv?04119000). Due to the unreliability of basing bankfull flow on field indicators, bankfull flow was determined to be 13,000 cfs based on records from NOAA.

In naturally functioning river systems, bankfull flow typically occurs during flow rates with return intervals of between 1.5 and 2 years. Although the return intervals for the larger floods (2-year and greater) were determined through correspondence with EGLE staff and in reference to earlier hydraulic models, the return intervals of lesser flows were determined using Log-Pearson Type III distribution calculations based on gage flow records. These results are presented in Figure 9. The return interval for the bankfull flow of 13,000 cfs was determined to be 1.4 years.

Figure 8: Bankfull flow Indicator

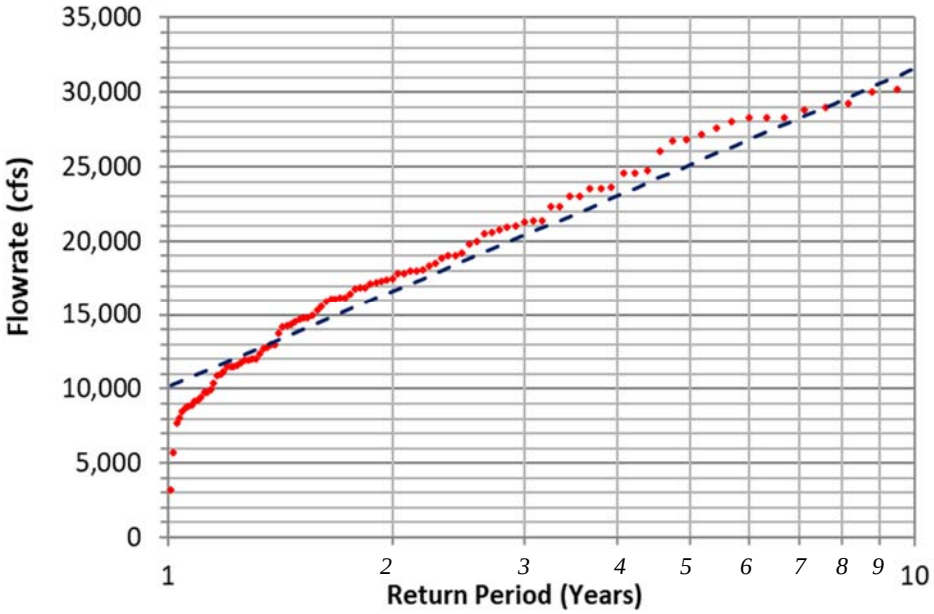

Figure 9: 1-year to 10-year Return Interval Flowrates determined using Log-Pearson Type III distribution calculations

Within the project reach, bankfull channel width ranges from 450 feet to 510 feet, with an average of 475 feet, and flow depth ranges from 7 feet to 11.5 feet, with an average of 9 feet. A typical cross section of bankfull conditions is presented in Figure 10.

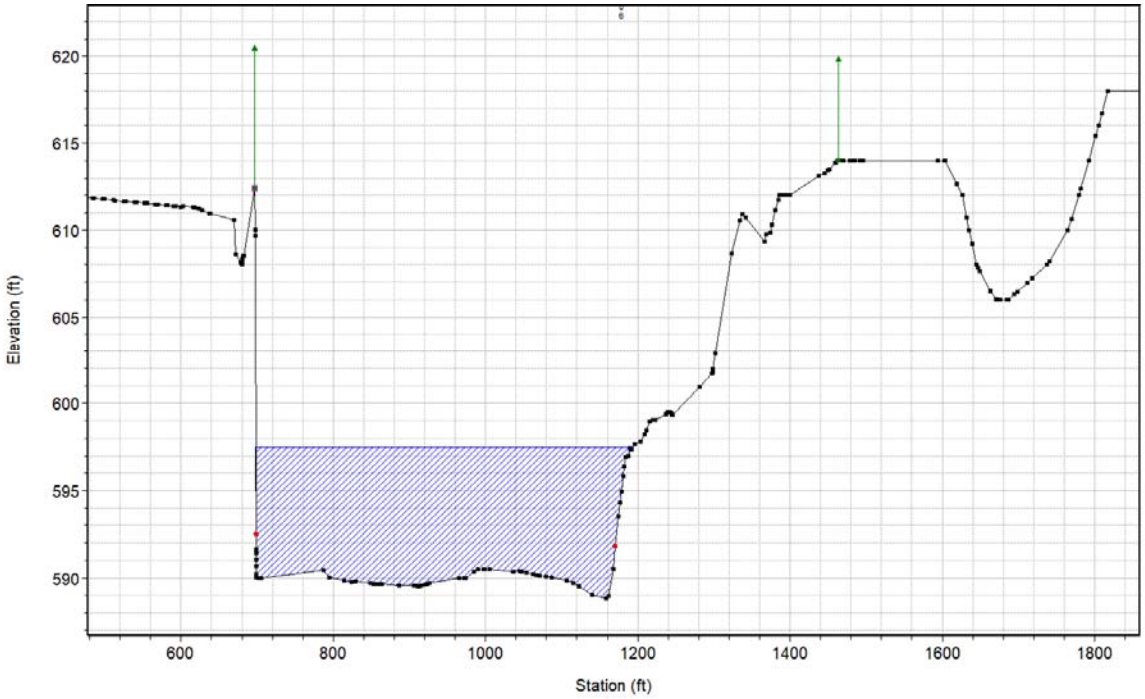

Figure 10: Typical Bankfull Cross Section

2.5.0 BANKFULL WATER SURFACE PROFILE

Due to the change in bed slope near Fulton Street and relatively flat reach downstream, much of the project reach is "submerged" by tailwater downstream of the project reach during the bankfull discharge of 13,000 cfs. This is evident when comparing the change in bed elevation to the change in water surface elevation during bankfull flow; bed elevations increase by more than five feet from 585.6' to 590.9' and corresponding water surface elevations increase less than one foot from 597.0' to 597.9'. A profile with approximate slopes is presented in Figure 11.

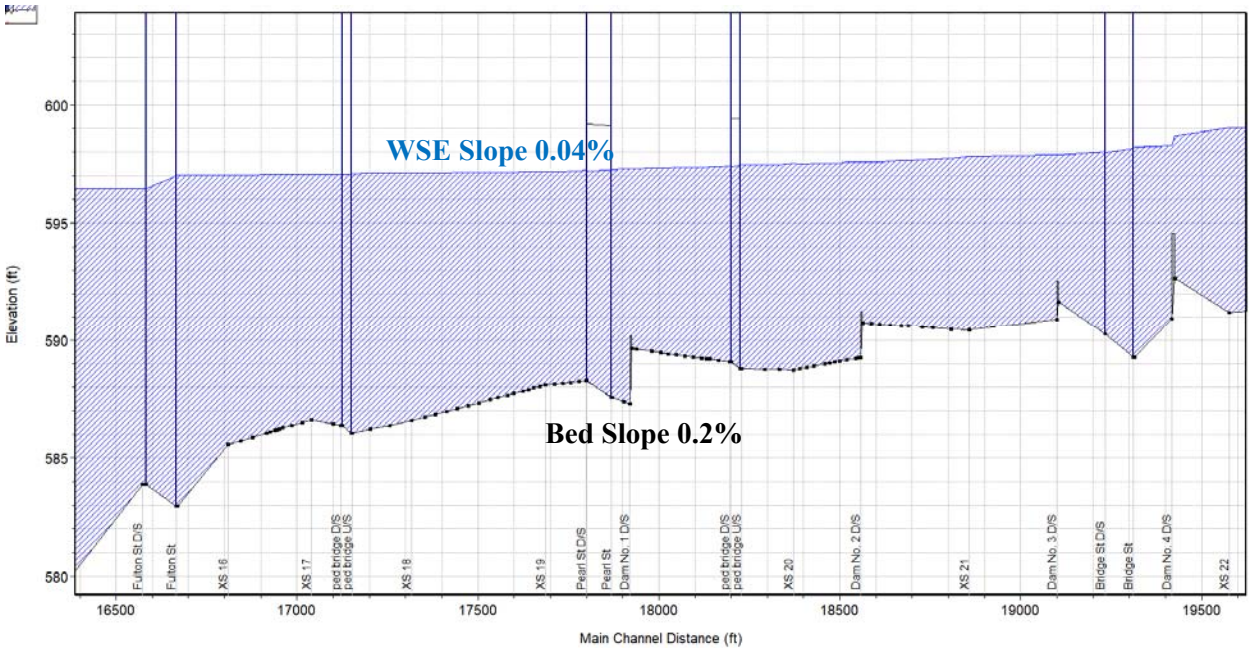

Figure 11: Project Reach Bankfull (13,000 cfs) Profile

2.6 WETLANDS

The Michigan Final Wetlands Inventory (MDEQ 2019) and the National Wetlands Inventory (NWI) (USFWS 2018) were both reviewed to determine the presence/absence of mapped wetland features within the portion of the Project area between the 6th Street Dam and Fulton Street. Neither database shows any wetlands in this portion of the Project area. However, wetland delineation surveys have identified five riverine wetlands currently in or near this area (Golder 2014 [TOC No. 17]; Fishbeck 2019 [TOC No. 17]. Because these features lie within the river banks, the character of these wetlands depends on river stage (depth). They are typically sparsely vegetated except for a few shrubs, primarily small willows (*Salix* sp.), near the banks, although they exhibit submerged aquatic vegetation, emergent vegetation, or both for at least part of the growing season. sp.), near the banks, although they exhibit submerged aquatic vegetation, emergent vegetation, or both for at least part of the growing season.

From upstream to downstream, the first wetland is located on the right descending bank just south of the 6th Street Dam and extends approximately 300 feet south (Golder 2014). The second wetland is located on the right descending bank adjacent to Ah-Nab-Awen Park, between the second and third low-head dam (Fishbeck 2019). The third wetland is located on the left descending bank in front of the DeVos Place Convention center. The fourth wetland lies along the right descending bank from approximately 100 feet downstream of the concrete patio at Ah-Nab-Awen Park to the Gillett Bridge (Fishbeck 2019). A fifth wetland extends along 200 feet of the left descending bank between the Blue Bridge and Fulton Street (Fishbeck 2019).

At the request of EGLE staff in October 2023, Fishbeck developed a wetland boundary verification memo to be included in the permit application package. The intent of the memo was to inspect wetlands within the project area, verify the previously delineated wetland boundaries, and update the wetland boundaries, if needed. The wetland survey determined there were minor changes in wetland boundaries. Wetland 7, wetland 10, and wetland 12 had slight changes to the wetland boundaries with wetland 12 having the largest change as the boundary was extended slightly as a result of erosion and river scour that created a flood bench that supports wetland vegetation. The project will have no impacts in the expanded wetland footprint for wetland 12. The full Wetland Boundary Verification memo from Fishbeck can be found ins (Fishbeck, 2023)

Wetlands within the main portion of the Project area are small, totaling less than 1 acre. Substrates within these features contain concrete, boulders, riprap and other non-natural materials (refuse), and overall wetland quality is low. Common hardy species, including sandbar willow (*Salix exigua*), eastern cottonwood (*Populus deltoides*) and the invasive reed canarygrass (*Phalaris arundinacea*) grow around and through gaps in these coarse materials. Various portions of these wetlands exhibit emergent, scrub-shrub, and forested wetland characteristics. Portions of these wetlands consist of fluvial deposits of sand, indicating that the configuration and extent of these wetlands may change periodically based on river flow.

The riverine nature of these wetlands is not conducive to some of the benefits usually associated with wetlands, such as water retention, biological productivity, and the removal of nutrients and other potential pollutants. However, they do provide habitat for fishes and other aquatic animals.

2.7 AQUATIC HABITAT AND BIOTA

There are existing populations of walleye (*Sander vitreus*), smallmouth bass (*Micropterus dolomieu*), Salmonids (*Oncorhynchus spp., Salmo spp., Salvelinus spp.*), and other non-migratory fishes in the Grand River. Diverse mussel species also have notable ecological presence within the Project reach. The existing aquatic habitat consists of relatively uniform depths and velocities with minimal deep holes or slower moving water. Fish exploit the tailwater behind the dams for holding areas. Some areas of more suitable conditions for mussels were observed during survey efforts; these generally were found in areas with gently sloping cobble/gravel bars where flow conditions become more diversified. For additional background information, see Section 3.0 of the Biological Assessment (EcoAnalysts, 2024)[TOC No. 24].

2.8 FISH PASSAGE AND LAMPREY ESCAPEMENT

Migratory upstream passage of important aquatic organisms is impacted by the low-head dams within the Project reach, which limit passage during some flow rates. However, unrestricted passage through the project reach only exists for the strongest swimming fish such as steelhead and salmon, which are naturalized but not native Great Lakes fish species. Although mussels do not migrate, their offspring disperse through distribution of glochidia on the gills of fish. Fish hosts of a federal and several state threatened and endangered species [logperch (Percina caprodes), minnows (Cyprinidae), catfish (Ictaluridae), and sunfish (Centrarchidae)] are restricted in upstream mobility past the low-head dam just upstream of Bridge Street and cannot pass downstream without washing over the crest.

The 6th Street Dam is considered by the Great Lakes Fishery Commission (GLFC) to provide a level of sea lamprey (Petromyzon marinus) migration control, although there have been reports of sea lamprey passing upstream of the dam to spawn (USFWS, 2013, 2024).The ability of the 6th Street Dam to continue to provide sea lamprey control as a long-term solution is unknown due to its age and ongoing dam deterioration. The Project has been evaluated and designed to maintain the current level of sea lamprey barrier effectiveness at 6th Street Dam.

2.9 RECREATIONAL USE

Currently, recreational fishing is popular in the Grand River within the Project area. Fishing from the shores and from boats is common, especially during salmon and steelhead spawning in the fall and spring. Angler counts have been conducted for the past four years and has recorded how the majority of angling occurs just below the 6th Street Dam, especially by wading when flow velocities and water depths permit. Recreational activities other than angling are not currently supported by the project reach.

The low-head dams pose a significant safety concern. There have been instances of people either floating over the dams or getting too close to the recirculating tailwater downstream of them while boating or wading, with some instances resulting in injuries and/or fatalities.

2.10 GEOTECHNICAL

The *Map of the Surface Formations of the Southern Peninsula of Michigan*, published by the State of Michigan, indicates the site is in an area of glacial outwash. The Grand River Valley is known to have been a major channel of glacial water flows. Near-surface soil conditions typically are found to be primarily granular with numerous cobbles and boulders, erratics from a distant geologic source. Several areas along the west and east riverbanks are known to have been low-lying floodplain areas prior to development of the area and have been filled with a variety of uncontrolled urban fill materials. Some fill material may have originated from dredging the main channel.

The proximity of bedrock to the riverbed throughout the project reach is relatively shallow compared to other parts of the Grand River. Bedrock includes a limestone and sandstone cap of the Bayport Formation from the north end of the downtown reach of the Grand River to the Gillett Bridge where the Bayport Formation ends and the underlying weathered shale and gypsum of the Michigan Formation continues south below the overburden soil. The top of the Bayport Limestone is exposed at the riverbed at the site of the fish ladder and 6th Street Dam and floodwall drawings in the vicinity indicate bearing directly on bedrock. Near Pearl Street and south where the Bayport Limestone is absent, the Michigan Formation Shale is approximately 10 to 30 ft below the alluvial riverbed.

Subsurface Conditions

During the development of the area during the late 1800's and early 1900's, placement of available miscellaneous material was common to raise low-lying riverbank levels. This fill created additional property for development as well as flood protection for nearby residences and businesses and defines what is now the current river boundary. A majority of the existing riverbanks in the project reach are therefore composed of miscellaneous fill material extending to depths up to 20 or 30 ft.

The miscellaneous fill material is composed of a highly variable assortment of granular and cohesive soil, boulder and cobble (primarily granite erratics), organic material (topsoil, peat and wood), building debris, cinders, brick and the like. Directly adjacent to and within the river channel, granular glacial outwash and post-glacial alluvium are present below the miscellaneous fill material below which relatively shallow bedrock is present as previously discussed. Native cohesive soil is also encountered adjacent to and within the river channel most often in the form of highly weathered shale above more competent shale. A summary of subsurface conditions described at various bridges crossing the Grand River within the study area is provided below including the approximate depth to bedrock and bedrock type.

Table 4: General Subsurface Conditions Encountered at Bridge Structures

Bridge Structure	Overburden Soil	Bedrock Type	Bedrock Depth (ft)
Ann Street	Granular	Limestone	> 60
Leonard Street	Granular	Limestone	1 to 7
Sixth Street	Granular	Limestone	1 to 2
I-196	Granular	Limestone	2 to 3
Bridge Street	Granular	Limestone	3 to 11
Gillett Bridge	Granular	Shale and Gypsum	20 to 30
Pearl Street	Granular	Gypsum and Shale	26 to 30
Blue Bridge	Granular	Gypsum and Shale	10 to 15
Fulton Street	Granular	Shale with Limestone	26 to 30
Wealthy Street	Granular	Shale	7 to 9

Note: Bedrock depth provided is approximate and is measured from bottom of river.

Historical documents indicating the foundation-type and bedrock depth at the Gillett and Blue Bridges were not found during our research. Bedrock information provided in Table 4 for the Gillett and Blue Bridges is based on soil borings performed near these structures.

Mine Research

Gypsum mining formerly located near the study area includes the Plaster Creek Quarry, located southwest of the project limits and the Powers Mine located within the south end of the project. The presence of surface beds of gypsum near Plaster Creek allowed for the formation of an open quarry and corresponding mill around the mid-1800's which remained in operation until the early 1900's. Subsequent development of the area has resulted in filling of the former quarry.

Approximate mining limits were obtained from *The Gypsum of Michigan and The Plaster Industry*, Volume IX, Part II, 1904. Records indicate that a mill was constructed directly above the mine shaft. Historical photographs and city directories place the mill at the northwest corner of the existing Blue Bridge west abutment (former Grand Rapids & Indiana Railroad Bridge).

Based on the existing site topography and no indication of significant ground subsidence in the area, it is suspected that the mine shaft was closed and filled and the underground mine rooms allowed to fill with water. A 1955 letter from a Grand Rapids Public Museum Employee stated that the mine was filled in some time after it was closed. Additional information regarding the closure and possible filling of the mine could not be found.

Materials Testing Consultants (MTC) has performed soil borings directly south and north of the Blue Bridge on the west bank of the Grand River for the GVSU Eberhard Center Project and for the Grand Rapids Public Museum Project with no indication of a mine shaft or void within bedrock encountered to depths up to 82 ft below the former ground surface at the boring locations. The boring information obtained by MTC to-date within this area lends further evidence to historical information describing the mines location, footprint and impact below ground.

Geotechnical Findings and Recommendations

The available information suggests the Grand River originally (prior to City's development in the mid 1800's) dropped 18 ft in elevation in a distance of a little more than one mile. This region of the "Grand Rapids" extended from the approximate current alignment of Leonard Street southward to approximately the current Gillette Bridge. We suspect the Grand River throughout much of the rapids was flowing upon or very near the top of bedrock surface of the Bayport Limestone Formation. It is expected that numerous boulders and cobbles were present in the region of the rapids as glacial outwash flows would have deposited such erratics. Although several feet of variation is noted, the top of bedrock at Leonard Street is approximately elevation 600 ft, while it is approximately elevation 590 ft at Bridge Street. Floodwalls, bridges and the 6th Street Dam throughout this area are largely founded on bedrock.

The gravity sections of boulder floodwalls north and south of Pearl Street are believed to have been constructed with primarily granite boulders pulled from the river and are founded at the river bottom with very little embedment or scour protection.

Soil behind the floodwalls and along the Grand River embankments is primarily miscellaneous fill over shallow bedrock throughout the region of former rapids and miscellaneous fill over postglacial alluvium both north and south of the former rapids. (MTC, 2015). Geotechnical findings are included in TOC No. 15 Geotechnical and Substrate Data and Findings.

2.11 SEDIMENTS

Sediment samples were collected using a petite Ponar Grab sampler on February 20, 2016. The Ponar sampler was lowered from a boat at the sampling locations to the river bottom, released to collect the sample and raised by hand after which the sample was retrieved by an MTC engineer. Retrieved samples were transported to the laboratory for gradation testing.

At each sampling location, about 12 to 15 attempts were made to collect a sediment sample at the river bottom using the Ponar sampler. Multiple attempts were necessary due to the presence of cobble and possible boulder which frequently resulted in little to no recovery. At Sample Location 3, MTC was not able to collect a representative sample of the sediment.

Supplementary probing was performed along the sides of the boat in a repeatable pattern to subjectively evaluate the consistency of the river bottom based on (1) presence of cobble and boulder greater than or equal to 6-inches in size and (2) presence of sand, gravel and cobble smaller than 6-inches in size. Sieve analyses were performed on retrieved samples per ASTM D6913 with material larger than 2-inches measured individually using calipers. A summary of sampling locations and the river bottom consistency based on probing efforts is provided in Table 5. The sediment sampling locations are presented in Figure 12. Refer to TOC No. 15 for substrate sampling data.

Additional sediment sampling was performed in August of 2020 in the locations of proposed excavation for construction of the in-channel features associated with alternative 3a. This effort focused on sampling fine material to evaluate contaminants. Refer to TOC No. 15 for the sampling report and contaminant testing results.

Table 5: Sediment Sampling Location Summary

Sample Location	Location (MI State Plane South)		Water Depth (ft)	River Bottom Consistency Based on Probing (%)	
	Northing	Easting		< 6-inches	≥ 6-inches
1	536129	12773066	4.5	25	75
2	536295	12772921	4.0	10	90
3	536623	12772963	4.2	10	90
4	536936	12773212	2.5	15	85
5	537353	12773028	3.7	50	50
6	537428	12773240	3.0	60	40
7	537827	12773063	2.7	75	25
8	538296	12773381	3.9	40	60
9	538890	12773427	5.8	85	15
10	539147	12773180	3.5	50	50
11	539485	12773506	6.8	Suspected bedrock

3.0 PROJECT REDESIGN PROCESS AND FRAMEWORK OBJECTIVES

The Project that is the subject of this permit application is the result of an iterative redesign process that took place from March 2023 until the time of application submission in 2024. In March of 2023 the project design team met with federal and state regulatory agency staff and developed an agreed upon framework and objectives for a successful project. The following framework objectives were agreed upon by all parties prior to initiating the redesign process:

- Remove the low-head dams and the associated public safety hazards;
- Achieve fish passage and aquatic habitat enhancement targets as determined by MDNR and project team;
- Diversify recreational opportunities;
- Develop an aesthetically and functionally natural stream design, within the parameters of a large urban river with floodwalls, a constricted floodplain, and multiple bridge crossings;
- Include safe river access consistent with identified objectives and compatible with projects adjacent to the river;
- Protection of critical infrastructure;
- Restoration of rapids;
- Avoid and minimize bed instability and public safety concerns associated with increases in flow velocities and scour potential.

The redesign process relied heavily on the direct coordination with EGLE and MDNR, as well as iterative correspondence with EGLE, MDNR, USFWS, and other stakeholders to achieve the agreed upon framework objectives. Multiple small group meetings occurred since March of 2023.These small groups included staff from MDNR Fisheries Division for fish passage, EGLE for wetlands, flooding/harmful interference, and state permitting, GLFC and USFWS for sea lamprey escapement, and USFWS and MDNR for endangered species.

3.1 PROJECT CONSTRAINTS:

Through the previous design process that spanned nearly 15 years, several constraints on the project were identified. The design concepts, iterations and alternatives presented in this report have been iterated based on these identified project constraints. Project stakeholders analyzed how the various project designs achieved the identified goals and satisfied the constraints. The design process and evaluation of goals and constraints for the project has benefited from extensive and ongoing coordination with the regulatory agencies, including MDNR, EGLE, USFWS, USEPA, and GLFC. Informal consultation with these agencies was initiated in early 2015 and has continued through the completion of this Report.

Throughout this process, topic focused meetings with regulatory agencies have been important in determining specific design elements that address project constraints. The design of the Project has been iterated and revised several times to address comments and concerns raised by regulatory agency staff. The Project presented in this Report is the product of these continued revisions and iterations in design and seeks to provide the most optimal balance of framework objectives while also satisfying constraints and minimizing impacts.

The following constraints were identified and minimizing impacts associated with these constraints has been a key goal of the project design process.

Constraints:

1) Flood conveyance;
2) Public safety;
3) Scour potential and integrity of existing infrastructure;
4) Sea Lamprey escapement at the 6th Street Dam; and
5) Impacts to wetlands and endangered mussels

-- END OF SECTION 3 --

4.0 PROJECT ALTERNATIVES AND REDESIGN CONCEPTS

The Project has been proposed because the past modifications to the Grand River, including the construction of the four low-head dams, have made the channel uniform and homogeneous, which in turn has impaired aquatic habitat, affected fish passage, created public safety hazards, and limited biological diversity of the Grand River. The Project proponents seek to address these impairments while also realizing the benefits of enhancing river access and use.

There is no other location where the benefits of the Project can be realized. The Project seeks to restore aquatic habitat in the Grand River, including demolition of four existing low-head dams (see Section 5.1 of this report). Pursuing restoration opportunities at other locations would not allow removal of the four low-head dams, the restoration of diversified aquatic habitat dependent on steep gradient hydraulics, or the revitalization of the Grand River through downtown Grand Rapids. The Project purpose could not be achieved at another location.

4.1 PREVIOUSLY CONSIDERED ALTERNATIVES

The prior permit application for the project, as referenced in Section 1, analyzed seven different design alternatives. Those alternatives were:

- Alternative 1: No Action
- Alternative 2: Dam Removal Only
- Alternative 2b: Dam Removal with expanded grading
- Alternative 3a: Dam Removal with substrate enhancement (Previous Preferred Alternative)
- Alternative 3b: Dam removal with substrate enhancement
- Alternative 3c: Dam removal with substrate enhancement
- Alternative 4: Dam removal with scattered boulders

As a result of the prior permit application process and the ultimate objection of Alternative 3a, the seven previously analyzed alternatives have been eliminated for additional study or review because:

- **Alternative 1:** Alternative 1is the no action alternative and leaves the river in its existing degraded state and does not achieve any of the project goals and objectives. Alternative 1 would leave four dangerous low-head dams in place and not improve access or usability for the community.
- **Alternative 2 & 2b:** Alternatives 2 and 2b remove the dangerous hydraulics associated with the four low-head dams but produce potential substrate stability concerns resulting from the lack of grade control provided within the Project reach. Alternative 2 and 2b do not meet the agreed upon framework objectives.
- **Alternatives 3a, 3b, & 3c:** Alternative 3a had approximately 11 acres of permanent direct impact area to the river bottom and had an expansive footprint of temporary direct impact areas during construction, which included large alluvial coffer dams to isolate portions of the channel. Following the objections to the previous design as noted in the introduction, the City of Grand Rapids chose to withdraw the application for Alternative 3a and work with EGLE to develop a new design alternative that further reduced impacts. Alternatives 3b & 3c had larger amounts of fill than 3a and also demonstrated increases in the modeled 100 year flood elevations. Alternatives 3a, 3b & 3c do not meet the agreed upon framework objectives.
- **Alternative 4:** This alternative eliminates the hazardous low-head dam hydraulics and adds aquatic habitat enhancements in the form of scattered boulders. However, the removal of existing grade control results in potential substrate stability concerns resulting from the lack of grade control provided solely by scattered boulders within the project reach. This alternative does not meet the agreed upon framework objectives.

4.2 REDESIGN CONCEPTS

Following the withdrawal of the permit application for the previously preferred alternative, the project team met with agency representatives and agreed on the framework objectives discussed in Section 3 that would guide the efforts for a new project design. As part of the redesign process of 2023-2024, EGLE and MDNR representatives expressed a desire to develop additional design concepts to further avoid, minimize, and mitigate impacts to the aquatic resource. Agency staff decided the design team needed to use the former Alternative 2b (Dam removal with expanded grading limits) as the starting point for the project redesign efforts.

Six additional design concepts were developed, and explored different locations, configurations, and number of proposed hydraulic grade control features, along with other natural channel design concepts such as w-weirs, rock arch ramps, and emergent habitat boulders. The six redesign concepts also varied by degree of replaced grade control within the reach, ranging from approximately 30% of replaced grade control provided by the four low-head dams to 100%.

The six redesign concepts included:

- Concept #1: Dam removal with one hydraulic grade control feature at the Dam 3 location and incorporated scattered boulder.
- Concept #2: Dam removal with one hydraulic grade control feature at the Dam 2 location and incorporated scattered boulder.
- Concept #3: Dam removal with two hydraulic grade control features, (Dam 3 location & Dam 2 location), and incorporated scattered boulder.
- Concept #4: Dam removal with two hydraulic grade control features, (Dam 2 location & Dam 1 location), and incorporated scattered boulder.
- Concept #5: Dam removal with three hydraulic grade control features, (Dam 2 location, Dam 1 location, & just downstream of Pearl Street Bridge), and incorporated scattered boulder.
- Concept #6: Dam Removal with four hydraulic grade control features, (Dam 3 location, Dam 2, location, Dam 1 location, and just downstream of Pearl Street Bridge, and incorporated scattered boulder.

4.2.0 METRICS

The metrics used to select a concept design and develop a permit are discussed below. These metrics evaluated seven categories, which were identified as important to the agreed upon framework objectives.

1. **Grade Control and Distribution of Hydraulic Gradient**
   The degree to which each concept replaced the grade control function of the existing low-head dams and distributed the hydraulic gradient of the river over the Project area was identified as the driving design consideration and was therefore first evaluated by the design team (with collaboration from EGLE and MDNR).

   Replacing less grade control within the reach allows for more hydraulic gradient, or energy, of the river to be expended over areas of existing streambed. This results in secondary hydraulic impacts such as decreased flow depth and increased velocities, shear stresses, and scour potential.

2. Aquatic Habitat

Several metrics were evaluated to assess aquatic habitat among the range of concepts. These included:

- Available habitat. This was the wetted area at 890 cfs (7Q10 flow rate). Concept selection was in favor of minimizing reductions to this area.
- Uninhibited movement for fish. These were areas with less than 3 ft/s flow velocities during several flow rates and at least 0.75 ft of flow depth. Concept selection was in favor of increasing this area.
- Deep-water and pool habitat. These were areas with greater than 4 ft of flow depth. Concept selection was in favor of increasing this area.
- Suitable spawning habitat for Lake Sturgeon. These were areas with flow velocity between 1.6 and 4.3 ft/s and substrate size between 0.4 and 3.3 ft in diameter. Concept selection was in favor of increasing these areas.
- Suitable flow conditions for mussel habitat. These were areas with minimum flow velocities between 0.12 and 0.5 ft/s and non-depositional for sand during 3,900 cfs (shear stress greater than 0.01 lb/sf). Concept selection was in favor of increasing these areas.

Other influential impacts were evaluated for fish and mussel species to inform the design, including holding area and uninhibited movement for fish and suitable flow conditions for mussel habitat. Of the remaining metrics, most were compared between concept designs but not evaluated further due to either little change between most concepts or because they were less prioritized than other metrics, such as minimizing area of direct impact to the existing streambed.

3. Fish Passage

Fish passage was evaluated based on metrics developed in collaboration between biologist for the Project team and MDNR Fisheries. These included average velocities and minimum flow depths, and considered the burst and sustained swimming abilities of several resident fish populations (Encompass, 2024). Concept selection was in favor of optimizing fish passage.

4. Avoid and Minimize Impacts to Aquatic Resources

The metric that had the most impact on concept selection, and continued refinement of that concept, was the area of direct impact to the existing streambed. Secondary impacts associated with the aquatic habitat metrics listed above were also considered.

Discussions on how the design avoided and minimized impacts are included in section 5 of this report for permanent impacts and in section 6 for temporary impacts.

5. Bed Stability

To evaluate bed stability, a factor of safety against substrate mobility was assessed. This factor of safety was defined as the critical shear stress of the substrate divided by the maximum calculated shear stress of the hydraulic models. The critical shear stress of a particle size is the shear stress at which that particle begins to mobilize from the bed. Because this is dependent on particle size, it is also dependent on substrate sampling data. Therefore, the evaluation of this metric relied on the findings of the series of substrate sampling efforts for the Project (MTC, 2015-2020). The concept selection was in favor of a minimum factor of safety of 2.0.

6. **Bridge Protection**
   The HEC-18 Manual for pier scour was used to calculate scour depths at all bridge crossings within the Project area. Any bridges with increased calculated scour depths would need to be fully evaluated in the bridge scour analysis for the project as design progressed. Therefore, concept selection was in favor of minimizing increased calculated scour depths at any bridge crossing.

7. **Public Safety at Bridge Crossings**
   Bridge crossings are inherently more dangerous to users than areas of open channel. The metric considered to evaluate public safety at bridge crossings focused on the proximity of peak hydraulics to bridge piers. This metric is directly related to the level of grade control and distribution of hydraulic gradient discussed above. Removing grade control downstream of bridge crossings relocates the hydraulic focus of the river from the grade control (low-head dams) to the bridge crossing. This is due to the narrower flow paths beneath the bridges resulting from flow constriction around bridge piers. Increased velocities near bridge crossings reduces reactions time of users potentially floating into the piers and increases the pinning forces against the piers. The concept selection was in favor of minimizing accelerated flow velocities at bridge crossings.

   Through coordination between the City, GRWW, EGLE, and MDNR, this concern was considered in context with the degree of potential increased risk to public safety as well as the degree of other framework objectives achieved by each concept.

4.2.1 CONCEPT SELECTION

The selection of a concept was based on evaluation of the metrics discussed above, as well as the project constraints discussed in Section 3.

4.2.1.1 Concepts #1 and #2 (One grade control structure)

Concepts #1 and #2, each with only one grade control structure, resulted in the largest amount of increased velocity and scour potential over the areas of existing channel in the Project area. Although these concepts had the least amount of direct impact to the existing streambed, it was determined that they did not maintain enough grade control within the project reach, resulting in large areas of increased velocities and shear stresses which carried adverse impacts to fish passage, aquatic habitat, bed stability, public safety, and protection of critical infrastructure.

4.2.1.2 Concepts #3, #4, and #5 (two and three grade control structures)

Concepts #3, #4, and #5 replaced 60%-90% of the grade control function of the low-head dams, depending on crest elevations and headlosses over each grade control structure. These concepts were able to focus the distribution of the hydraulic gradient of the river at locations of stable fill material (grade control structures) in a way to achieve framework goals within the project reach. The less amount of replaced grade control function resulted in increased velocities and scour potential over the streambed upstream of the project to 6th Street Dam compared to existing conditions. These increases in the upstream reach carried with them potential adverse impacts to fish passage, aquatic habitat, streambed stability, protection of critical infrastructure, and public safety. These impacts were evaluated and considered against the improvements (and level of achieved framework objectives) within the Project reach.

4.2.1.3 Concept #6 (four grade control structures)

Concept #6 replaced the full grade control function of the low-head dams and maintained a similar upstream control elevation to low-head Dam 4. This concept had the largest area of direct impact to the streambed but was also able to avoid the adverse impacts to the upstream reach that

the other concepts could not, resulting in no change in upstream velocities, scour potential, or protection of critical infrastructure. In addition to having the largest area of direct impact to the existing streambed, this concept also resulted in modeled increases in tailwater elevations at 6th Street Dam during some flow rates, indicating a higher potential to change the barrier effectiveness of the 6th Streed Dam compared to the other concepts.

4.2.1.4 Selected Concept (Concept #4) and Preferred Alternative

Concept 4 emerged from the initial concept evaluation process as the concept that would best achieve the agreed upon project framework objectives and further avoid, minimize, and mitigate impacts to the streambed. Through significant coordination with representatives from MDNR and EGLE, Design Concept 4 was selected in August of 2023 as the concept that would be further enhanced and refined over a series of bi-weekly technical project team meetings with agency representatives from MDNR, EGLE, City of Grand Rapids, and Grand Rapids Whitewater. Through this collaborative design effort, it was determined that complete replacement of the grade control function of the low-head dams was unable to be achieved due to increases in modeled tailwater elevations at 6th Street Dam at some flow rates and the potential for decreasing the effectiveness of 6th Street Dam as a barrier to sea lamprey.

Concept #4 was preferred to Concept #5 due to having less direct impact area to the existing streambed. Concept #4 was preferred to Concept #3 because of the upstream grade control structure being located at Dam 2 instead of Dam 3, which is near a large 96" storm sewer and large floodwall on the east side, both carrying with them avoidable public safety concerns associated with ingress/egress and self-rescue. The location of Dam 2, adjacent to an existing and highly utilized public park, which will also be utilized as construction staging for the project, also made it a more advantageous location for the grade control structure.

The selected concept design was iteratively evaluated, modeled, and designed to be optimized for achieving the framework objectives, avoiding or minimizing adverse impacts to project constraints, and minimizing area of direct impacts to the existing streambed. Preliminary design drawings were developed to show locations and elevations of all proposed substrate enhancements.

On January 12, 2024, following review of preliminary design plans, EGLE staff communicated by email that they did not foresee any "redflags that would prevent the project from being successful" and supported the City in moving forward with submitting additional information to move into a formal permit review process with State and Federal agencies. As a result of this coordination with the agencies, Design Concept 4 was selected as the Preferred Project Alternative (Project) and is now the subject of this revised Basis of Design report and permit application.

The framework objectives and project constraints were all evaluated throughout the design of the preferred alternative. Several supporting reports have been developed to discuss these evaluations. Specific objectives or constraints are listed below along with corresponding references to the more-detailed reports which discuss how they have been evaluated.

- **Flood conveyance:**
  The Preferred Project Alternative has been hydraulically modelled and designed to maintain the City's freeboard deficient certification from FEMA. Localized increases in modeled flood stages occur within the project reach; however, the hydraulic evaluation of the project indicates that no harmful interference would result from the project. A CLOMR will be submitted to FEMA to fully address modeled increases in 100-yr flood levels.

Refer to TOC No. 5 Hydraulics Report and TOC No. 10 Temporary Conditions Hydraulics Report more detailed analysis and information.

- **Aquatic habitat, suitable flow conditions for mussel habitat:**
  The project is pursuing a Biological Opinion from the United States Fish and Wildlife Service. All impacts to mussels will be avoided and minimized. The Biological Assessment currently under review by United States Fish and Wildlife Service includes mussel relocation ahead of the project to occur in summer 2024.

  Within the direct impact area (45,445 m2) of the project, there are estimated to be 123 E. Triquetra, 1,800 Michigan TES, and 11,711 other unionid species. Within the indirect impact area (82,155 m2) of the project, there are estimated to be 222 E. Triquetra, 3,253 Michigan TES, and 21,171 other unionid species. Upstream of the project, the indirect impacts are estimated at 104 E. Triquetra, 1,521 Michigan TES, and 9,901 other unionid species. Downstream of the project, there are estimated to be no E. Triquetra, 8,325 Michigan TES, and 28,250 other unionid species.

  Mussels will be relocated from the direct impact areas. Loss of mussels will also be mitigated through the establishment of a mussel mitigation fund.

  Refer to TOC No. 24 Biological Assessment for more detailed analysis and information.

- **Fish passage:**
  A fish swimming performance analysis evaluated the Preferred Project Alternative at fifteen swim paths across four reaches of the project area and demonstrated passage through the project area. Within the evaluation, fish passage was predicted to occur at most difficult hydraulic scenarios and for each of the design elements – boulder clusters, W-weir, and riffles.

  Refer to TOC No. 14 Fish Passage Report for more detailed analysis and information.

- **Bed stability:**
  Incipient motion analyses, which compared modeled maximum shear stresses to critical shear stress values of sampled substrate sizes within the project area, demonstrated that existing and proposed substrates would remain stable with a minimum factor safety against mobility of 2.0. Isolated small areas calculated a factor of safety slightly less than 2.0; these are discussed and explained in TOC No. 6.

  Refer to TOC No. 6 Sediment Transport Report for more detailed analysis and information.

- **Bridge Protection:**
  Analysis of the hydraulic influence on bridge scour was performed for existing and proposed conditions of the Grand River at Grand Rapids, MI. Hydraulic modeling and data analysis using the standard engineering guidelines of HEC-18 indicate that proposed project actions will minimally affect the largest scour producing flows (100-yr and 500-yr return flood, with differences of ~0.5% or less). Increased scour potential is anticipated during lower flow rates (up to 13,000 cfs) at I-196; however, is not expected to erode the primarily bedrock streambed.

Two-dimensional modeling of temporary conditions highlighted the (low probability) of high-scouring conditions at Gillett Bridge if 7,500 cfs is exceeded during work isolation at the Dam 2 location.

Refer to TOC No. 7 Bridge Scour Report for more detailed analysis and information.

- **Sea lamprey escapement at the 6th Street Dam:**
  Modeling results indicate that tailwater elevations would remain at or below existing conditions, within modeling error. Based on this evaluation, the function of 6th Street Dam as a barrier to sea lampreys is anticipated to remain as effective as the existing condition.

  Refer to TOC No. 8 Hydraulic Influence at 6th Street Dam for more detailed analysis and information.

-- END OF SECTION 4 --

5.0 PROJECT DESIGN ELEMENTS AND CONSIDERATIONS

The preferred project alternative was developed by progressing the design of Concept #4, which included proposed grade control structures at the locations of Dams 1 and 2 in addition to bank vane structures and emergent habitat boulder downstream of Pearl Street. Through a collaborative effort with EGLE and MDNR, the Concept #4 design was iterated to optimize for framework objectives and project constraints while also avoiding and minimizing direct impacts to the existing stream bed. This section describes design elements and ways in which this was achieved through design.

5.1 DAM DEMOLITION

The demolition of the dams was determined to be important to achieving project goals and satisfying constraints. Various options considered for the low-head dam demolition are discussed in this section.

Each of the four low-head dams downstream of 6th Street Dam will be demolished so they no longer have a hydraulic control on the river. The low-head dams currently function to provide grade control throughout the reach and help prevent potential head cutting from occurring. Care must be taken with the demolition plan to not destabilize the channel bed or channel banks. Several dam demolition options were studied, including complete demolition of all concrete and partial removal of the concrete to an elevation that no longer influences the flow of the river. These options are discussed below.

5.1.0 LATERAL EXTENT OF LOW-HEAD DAM DEMOLITION

Since the original low-head dam construction and subsequent, often undocumented, modifications occurred over the past 100-plus years, the exact limits of the existing low-head dam structures are not explicitly known in all areas. The concrete dams may extend behind and beneath the floodwalls and adjacent pathways on the east side of the channel, as well as through the riprap bank and under the pathways on the west side of the channel. Three options were considered for lateral extent of dam demolition:

1) Leave dams in place. Leaving the low-head dams in place would not meet the Project purpose and therefore was not considered as a feasible alternative.

2) Remove the entire structure. Depending on the lateral extent of the low-head dam, this option may necessitate excavation, removal, and replacement of existing infrastructure, such as floodwalls, riprap banks and concrete pathways in the vicinity of the dams and overbank areas.

3) Demolish the dams to a lateral extent where the remaining structure is no longer visible or affects the river hydraulically. To the degree possible, the dams would be removed to match the bank grade on both sides of the channel. On the east side of the channel, the dams would be removed laterally to the existing floodwall, finished with a vertical saw cut near the floodwall. On the west side, the dams would be removed to where they meet the existing bank or slightly beyond. Any exposed concrete would be covered with stable material and planted to match existing site conditions.

Due to the potential impacts to floodwalls and other critical infrastructure, the preferred dam demolition option is to remove dams laterally only to the extent to which they are no longer visible and no longer influencing the hydraulics of the river. This option will allow for additional in-channel fill to accomplish project goals, while protecting existing critical infrastructure, reducing construction costs, and reducing the in-water construction footprint associated with complete removal.

5.1.1 VERTICAL EXTENT OF LOW-HEAD DAM DEMOLITION

Each dam location has a specific maximum elevation to which finished grade should be established after demolition to eliminate all effects on hydraulics and allow maximum habitat improvements. Finished grade at the locations of Dams 1, 3, and 4 is the top of the footer elevation of the dam, right at the toe of the downstream face of the structure. Maintaining a 12" minimum cover of alluvium would necessitate complete removal of the dam structure within the channel at these locations, assuming the dam footers are set similar to what historic plans show. At the location of dam 2, some locations of the existing dam are greater than 24" below finished grade of the proposed riffle structures. In these locations, the contractor may remove concrete to an elevation of 24" or greater below finished grade and place coarse alluvium on top to form the constructed riffle.

A range of options have been evaluated to determine the elevations that the dams are to be removed to, at different locations of the river, including partial removal and complete removal of the dam and footer. The foundations of the dams vary from four to six feet in length (in downriver direction) and one to two feet thick based on historic construction plans. The dam foundations were likely poured directly onto the river substrate, without forms to define the bottom of the structure. Several options were considered for the vertical removal of concrete:

1) Leave dams in place. Leaving the low-head dams in place would not meet the Project purpose and therefore was not considered as a feasible alternative.

2) Remove to the elevation of proposed finished grades. This option would remove the concrete dams to the elevation of proposed finished grades without a 12" minimum cover of alluvium. Dam footer structures would be left in the channel for this option. The ability to achieve precise finished elevations for the concrete removal work would be dependent on the equipment required for removal. This option would include avoidance of exposed sharp edges to the maximum extent possible and spreading alluvium over the exposed foundations, though exposed concrete would likely exist in areas. This option avoids destabilizing these areas of the channel bed during construction and would correspond to lower cost for construction and materials. Although the concrete that would be left in the channel would not influence the hydraulics of the river, there may be areas of the channel that would have exposed concrete in the riverbed. This option was not determined to be the preferred option due to the potential of exposed concrete in the flowing river.

3) Remove all concrete associated with the dams from the channel. This option removes all concrete associated with the dams from the channel, including the entire foundation of the dams. The foundations of the dams would be excavated and removed from the channel, the underlying substrate would be verified to be coarse alluvium, and the excavation would be backfilled with riprap or very coarse alluvium with 12-inches minimum of alluvium placed as finished grade. If the substrate is a finer material, then some over-excavation with coarser material backfill would occur. Compared to Options 1 and 2 above, this dam removal option requires more extensive in-channel work and associated material costs, with approximately an additional 400-500 CY of excavation and backfill of riprap. This option would avoid exposed concrete in the riverbed. This is the preferred option in locations where dams are proposed to be removed and no substrate enhancements are proposed to avoid exposed concrete in the flowing river.

4) Combination of Options 2 and 3. A fourth option is essentially a combination of Option 2 and 3 above. Dam removal Option 4 establishes finished grade with at least 12" of alluvium placed on top of any existing concrete or placed riprap in the channel. Along areas of the

dams outside of the proposed grading footprint, concrete would be removed to at least 12" below existing grade, likely resulting in complete removal of the footers for several of the smaller low-head dams (Option 3 above). Areas of the dams within the grading footprint would be lowered to at least 24" below the finished grade elevations and would be covered with proposed fill. This is the preferred option because it avoids exposed concrete in the flowing river and provides potential for more efficient and cost-effective construction.

5.2 SUBSTRATE ENHANCEMENT IMPROVEMENTS

The main design components proposed as part of the Project are grade control structures (which include both constructed riffles and boulder arch structures), bank vane structures, and emergent habitat boulders. These design components function together to achieve the framework objectives of the project. The grade control structures function to distribute the bulk of the hydraulic gradient of the reach, the bank vane structures provide habitat diversity and improved public access, and the emergent habitat boulders enhance aquatic habitat, fish passage, and natural aesthetic function.

Constructed riffles would contain stabilizing riprap core structures within placed coarse alluvium with emergent habitat boulders. Boulder arch structures would have a diversified planform that emulates rock arch designs (Aadland, 2010) and W-weir structure designs (NRCS, 2007); each boulder arch structure would also have a downstream scour hole. Bank vane structures would be installed at locations of existing or future public access points and would function to provide slow-moving water and hydraulic diversity at these locations. Lastly, emergent habitat boulders would be placed in areas of existing riverbed to improve aquatic habitat and natural aesthetics. Refer to Figure 13 for a plan view of the proposed substrate enhancements.

Additional details and information on the design of these substate enhancements are discussed below.

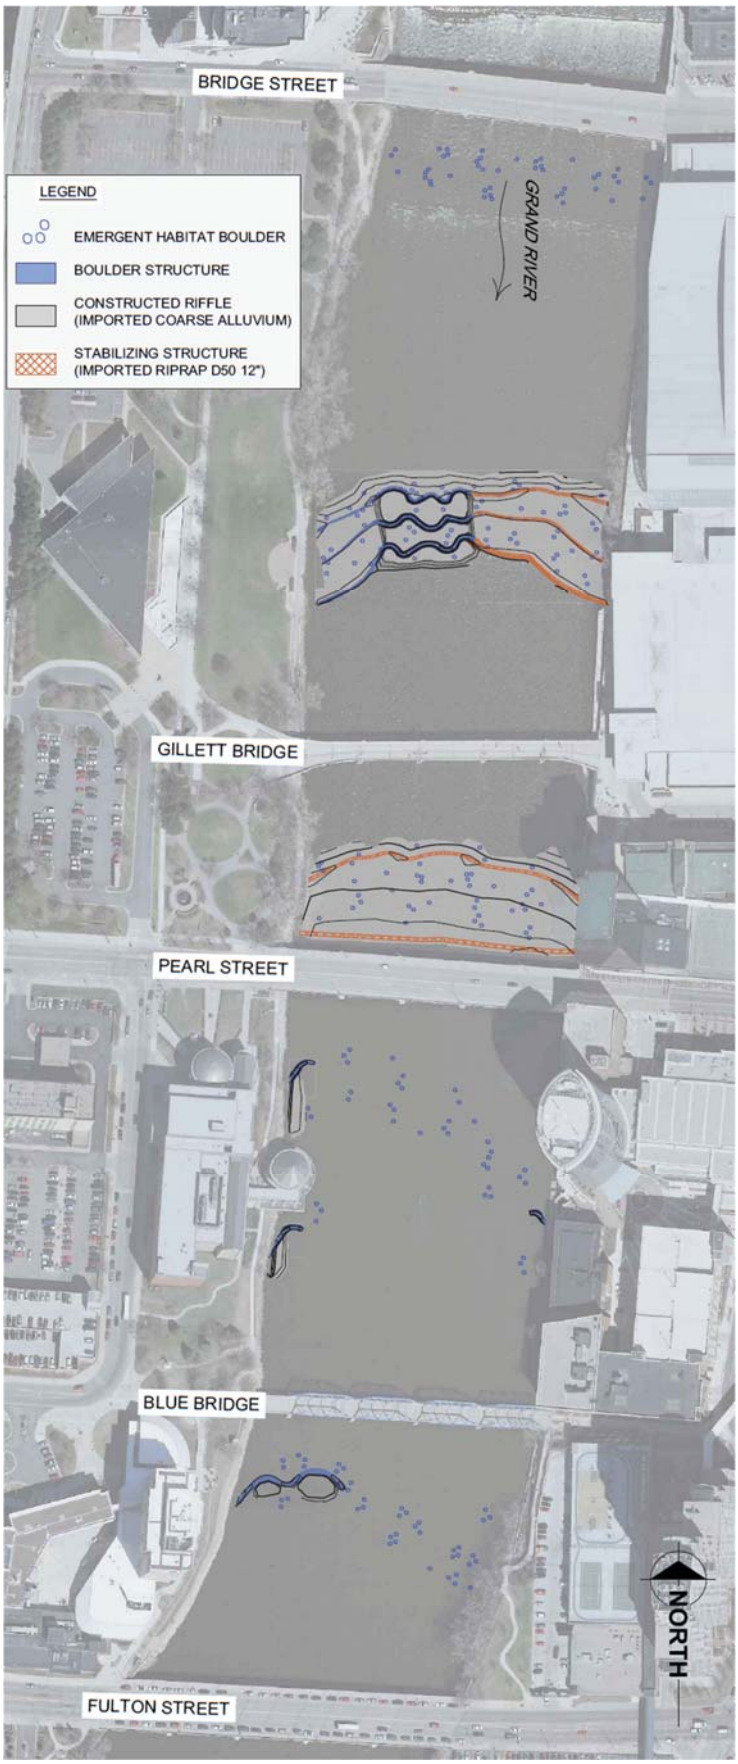

Figure 13: Proposed substrate enhancements

5.2.0 DESIGN DISCHARGES

The design of all substrate enhancement components has been based on the evaluation and hydraulic modeling for a wide range of flow rates, from extreme low flows (890 cfs) up to the 100-year flow event (50,000 cfs). The design discharges for any given area of proposed substrate enhancement are the flow rates at which a structure influences the hydraulics of the river; both downstream and upstream of the structure. Each structure will be submerged by tailwater at a different flow rate, depending on the location within the project reach. The backwater effects migrate from downstream to upstream as the flow rate increases. Once submerged, the structures would not generate hydraulics noticeably different from existing conditions at the same flow rate; the hydraulics would become similar to existing conditions as flow rates and tailwater elevations continue to increase.

5.2.1 GRADE CONTROL STRUCTURES

Two grade control structures are proposed as part of the project. The downstream structure, located between Gillett and Pearl Street Bridge near low-head Dam 1, would be a constructed riffle with emergent habitat boulders and stabilizing riprap core structures at the crest and toe. The upstream structure, located at the location of Dam 2 and adjacent to Ah-Nab-Awen Park, would have two constructed riffles (similar in design to the Dam 1 structure) on either side of a series of three boulder rock arch structures. These grade control structures would function to maintain grade control within the project reach while also functioning to achieve the framework objectives of the project.

5.2.1.1 Crest Elevations

Crest elevations of the proposed grade control structures have been set to provide an optimized balance of the framework objectives of the project with project constraints, which include fish passage, scour potential and integrity of existing infrastructure, sea lamprey escapement, and flood conveyance. The crest elevations for the preferred alternative were determined through the collaborative concept selection effort described in Section 4.

The crest elevations for the grade control structures have been set relative to one another so that the head loss, or change in water surface elevation, over each feature is consistent and the total change in water surface through the reach is gradually distributed. The crest elevations of the grade control structures were also set to minimize increased scour potential compared to existing conditions while balancing framework objectives and project constraints. The project design constraints most important in determining crest elevations include flood conveyance, sea lamprey escapement, bed stability, and protection of critical infrastructure. Boat passage and fish passage were also factors in determining crest height.

The project proposed to lower the hydraulic grade control at the upstream end of the project reach from approximately 595’ under existing conditions (Dam 4) to approximately 593’ under proposed conditions (at location of Dam 2). This allows more hydraulic gradient (energy) to be expended over existing substrates upstream of the project reach, between Bridge Street and 6th Street Dam. This may decrease depths as well as increase flow velocity and scour potential in that upstream reach, having potentially adverse secondary impacts to aquatic habitat, public safety, bed stability, and protection of critical infrastructure. These secondary impacts were evaluated and determined to be acceptably minor in magnitude, and also to be necessary to avoid modeled increases in tailwater at 6th Street Dam during some flow rates, which may impact the effectiveness of the 6th Street Dam as a barrier to sea lamprey. For more information, refer to TOC No. 8 Hydraulic Influence at 6th Street Dam.

Impacts to aquatic habitat were evaluated through the BA (TOC No. 24 Biological Assessment), the Fish Passage Report (TOC No. 14) and through personal coordination with EGLE and MDNR Fisheries. Potential impacts to public safety resulting from increased velocities upstream of the Project reach were evaluated through discussing the public safety metrics described in Section 4.2.0 with the City, EGLE, and MDNR. Bed stability was evaluated by comparing maximum bed shear stresses under proposed hydraulics with critical shear stresses associated with existing substrate sampling to determine the likelihood of increased substrate mobility under post-project conditions. A complete evaluation of substrate stability is presented in TOC No. 6 Sediment Transport Report. Protection of critical infrastructure was evaluated by referencing previous scour reports for bridges and calculating and comparing scour depths between existing and proposed conditions. Refer to TOC No. 7 Bridge Scour Report for more information.

The elevations of all grade control structures and other proposed improvements have been set to avoid increases in modeled flood risk or harmful interference. Refer to TOC No. 5 Hydraulics Report for more information.

5.2.1.2 Configuration

The configurations of the grade control structures were primarily based on framework objectives of achieving an aesthetically and functionally natural design to restore the rapids and improve fish passage, and was constrained by public safety, protection of critical infrastructure and avoidance and minimization of impacts.

The grade control structures are located within the footprint of the low head dam removal areas with minimally expanded grading limits. These grading limits have been reduced to the greatest extent possible. Maintaining open and connected swim paths for fish and minimizing areas where fish may need to traverse water to find more suitable passage hydraulics was also a key design element that influenced the configuration of the hydraulic features.

5.2.2 CONSTRUCTED RIFFLES

The design of the constructed riffles is key to the success of the Project. The proposed constructed riffles at the Dam 1 and Dam 2 locations function in concert with the boulder arch feature at the Dam 2 location to distribute most of the water surface gradient currently controlled by the four low-head dams. The constructed riffles provide improved fish passage connectivity and are intended to restore aquatic habitat and natural aesthetic as well as enhance downriver boating and angling.

Multiple options for riffle feature designs were evaluated throughout the project development process, which contain various horizontal limits of grading, slopes, finished grade variances, and materials. All these design parameters have been adjusted with input from the regulatory agencies to avoid harmful flood interference and minimize impacts on the existing riverbed, threatened and endangered species, and public safety, while maintaining fish passage and aquatic habitat improvement goals. A schematic of the constructed riffle at the Dam 1 location is presented in Figure 14, refer to Figure 16 for the riffles at the Dam 2 location. Options for riffle structure materials, footprint, and substrate thickness were analyzed, and are discussed below.

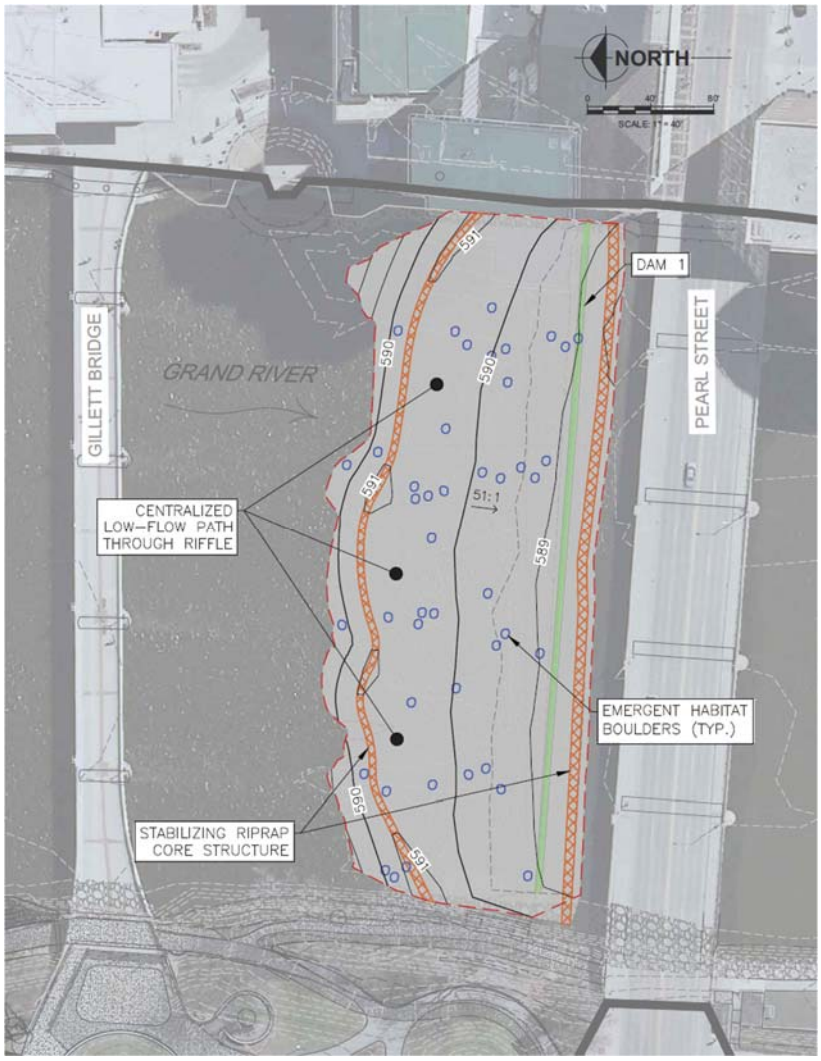

Figure 14: Constructed riffle grade control structure at the Dam 1 location

5.2.2.1 Constructed Riffle Materials

The size and type of the materials used to construct the proposed constructed riffles, including boulder, riprap, and alluvium, were determined by evaluating stability, aquatic habitat suitability, biological health, and user interface (i.e. wading and boating). Different ranges in gradation, type and angularity of rock (i.e. natural weathered rock versus more angular rock blasted from a quarry) of alluvium were considered.

Regarding size, coarser substrates would be more stable but may have reduced habitat suitability and user interface. A uniform gradation consisting of only coarse material contains more void spaces. This correlates to relatively less suitable aquatic habitat, poor biological health and mussel habitat, and increased foot entrapment potential and other user safety concerns. However, if material is sized too fine, long-term stability of the features may become a concern, resulting in higher potential for long-term repairs or rehabilitation costs. Gradations with large portions of finer material may experience "winnowing" over time that results in the removal of smaller material and the general armoring of the finished grading, which is also indicative of relatively less suitable aquatic habitat.

The preferred option is to install well-graded alluvium which includes a continuum of material sizes to fill voids and provide enhanced and diversified biological habitat for macroinvertebrates

within proposed riffles which are anticipated to see elevated dissolved oxygen levels (EPA, 2012). Well-graded alluvium is also important for mussel habitat while also remaining locally stable without mobilizing downstream (EcoAnalysts, 2020). Allowing the substrate to adjust locally to annual changes in flow conditions and establish a more natural bedform is a desired outcome of the project. Emergent habitat boulders will be selectively placed in the riffle sections to provide flow diversity.

The Project will utilize two size classes of imported alluvium for construction of riffle features and backfill around boulder and riprap. The size classes include fine alluvium and coarse alluvium. Imported alluvium will consist of clean, hard, durable, subrounded, and well graded material. Imported alluvium may be screened or crushed material, subrounded material is preferred. Unless specified in drawings, gradation shall match the gradations detailed in the tables below. Materials shall meet the following specification requirements.

- Minimum specific gravity of 2.55.
- Abrasion resistance by Los Angeles Machine; Test Method ASTM C535; Specification Requirement: 28% loss, maximum.
- Soundness by use of Sodium/Magnesium Sulfate, Test Method ASTM D5240-04 Standard Test Method for Testing Rock Slabs to Evaluate Soundness of Riprap by Use of Sodium Sulfate or Magnesium Sulfate; Specification Requirement: 10% loss, maximum.
- Soundness by Freezing and Thawing, Test Method ASTM D5312-04 Standard Test Method for Evaluation of Durability of Rock for Erosion Control Under Freezing and Thawing Conditions; Specification Requirement: 10% loss, maximum.

The gradations of the proposed imported substrate sizes were developed to address stability and resistance to shear stress, user safety, and aquatic habitat including biological health. Regarding stability, coarser substrate has been proposed in areas of higher calculated shear stresses. The d_{50} grain size of each gradation was set to be twice as large as the threshold mobile grain size associated with the maximum bed shear of the proposed hydraulics. The threshold mobile grain size was set to be the d_{30} size class. The imported substrate is proposed to be clean, rounded, and well graded in order to provide maximum benefit to aquatic habitat and closely emulate natural material. Well-graded gradations provide increased diversity in macroinvertebrate habitat within the substrate and provides improved mussel habitat. A larger percentage of finer material also increases the benefits to user interfacing through wading or contact with the bottom of a watercraft. Table 6 presents the preferred gradations for the coarse and fine alluvium size classes. These gradations are proposed in areas of relatively lower hydraulic shear stresses, where stability is less of a concern and improved aquatic habitat, biological health, and user interface can be emphasized.

Table 6: Fine and Coarse Alluvium Gradation (inches)

Weight	Indicator	Coarse	Fine
100%	Passing	30”	8”
60%-85%	Passing	20”	6”
35%-65%	Passing	12”	3”
25%-55%	Passing	8”	1.5”
15%-35%	Passing	4”	3/4”
0%-5%	Passing	1.5”	1/2”
	D_{85}	18”	6”
	D_{50}	12”	3”
	D_{30}	4”	3/4”

Figure 15: Coarse Alluvium Gradation Example

5.2.2.2 Constructed Riffle Footprint

The footprint areas of the constructed riffles were reduced from the prior project moving catch lines with existing grade as close as possible to the removal limits of the low-head dams. The final footprint areas were determined by the crest elevation and the slope off the crest to catch existing grade. The crest elevation determination is discussed in Section 5.2.1.1 The target slope of the riffle was between 1% and 2%, based on initial modeling results and consultation with state and federal agencies. These values were confirmed by comparing reference reaches and Newberry Riffle design guidelines. In addition to the basic geometry factors, site-specific constraints also affected the footprint area of the riffle features. These constraints included existing wetlands identified during the wetland delineation [TOC No. 17] and likely endangered mussel habitat areas identified during the mussel survey. Areas of proposed grading also considered existing infrastructure, including bridge piers, floodwalls, and pedestrian pathways and access.

5.2.2.3 Constructed Riffle Substrate Thickness

The proposed substrate thickness of the constructed riffles was determined by considering shear stresses to calculate needed substrate sizes. Once the gradation was calculated based on the expected shear stress and a factor of safety, the minimum thickness of the imported alluvium for the riffle structures was set to twice the d_{50} grain size of the proposed substrate gradation. This allows the alluvium to create a matrix and adds stability to the overall structure. In areas where the difference between existing grade and proposed grade is less than that the minimum thickness, the existing bed will be over excavated and backfilled with the proposed gradation.

5.2.3 CORE STRUCTURES

One function of the low-head dams is to provide grade control throughout the reach and protect against potential head-cutting. The existing configuration focuses the energy loss at each of the four dams, slowing down velocities over substrates upstream of each dam. The impacts to the

scour potential of existing substrates associated with removing the low-head dams was evaluated through the dam removal only alternative. Based on this evaluation, it was determined that maintaining stable grade control within the reach is important to avoid increased scour potential, bed mobility, and to protect critical infrastructure such as piers and floodwalls. Therefore, stable core structures were included within each proposed hydraulic feature. These structures are designed to be keyed into the existing bed, extending down to calculated scour depths. Coarse alluvium with emergent habitat boulders would be placed around these structures to establish the finished grade of the riffles. Options for core structure materials, footprint area, and dimensions and elevation were analyzed, and are discussed below.

5.2.3.1 Core Structure Materials

The core structures consist of large material sizes, including boulder and riprap, and extend from scour depths up to the crest elevations of each hydraulic feature, as shown in the construction drawings [TOC No. 3 Construction Plan Sheets]. Boulder is used as the stabilizing core structure for the west half of the Dam 2 grade control structure; riprap is used at all other locations. The core structures would establish finished grade at the crests of the riffle features. The majority of finished grade of the riffle structures consists of coarse alluvium fill and emergent habitat boulders that have been sized to remain locally stable.

Materials considered for the core structures within the riffles represent varying factors of safety for substrate stability, aquatic habitat suitability, modeled flood risk, and user interface (i.e. wading and boating). Riprap, boulder, alluvium, and concrete were all considered as material options for the core structures.

Concrete would be the most stable and carry the least potential for future maintenance; however, biological health and natural aesthetics ruled it out from selection as the preferred material type. Boulder is larger than riprap and offers a high factor of safety for stability but also results in higher modeled flood elevations due to modeling parameters associated with the larger material. An alluvium core would provide the most suitable habitat for mussels and other aquatic species, as well as the most convenient interface for users, but would have the lowest factor of safety for substrate stability over the lifetime of the project due to the smaller size of the material and would not be prudent. Riprap represents a core material option with a higher factor of safety against substrate mobility than alluvium and has a lower modeled flood risk than boulder. Because it is stable and has less flood conveyance impacts, riprap was selected as the material for the core structure within the riffle features.

5.2.3.2 Core Structure Footprint

The footprint areas of the core structures were determined based on the proposed grading of the constructed riffles. Once a crest elevation was established, the height of the core structure, including key-in depth, was determined. This calculated height and a minimum side slope of 2:1 for riprap and 1:2 for stacker boulder dictated the footprint area.

5.2.3.3 Core Structure Dimensions and Elevations

The dimensions and elevations of the core structures were determined by considering the elevation of finished grade, calculated scour depths, and substrate sizes. Core structures extend from finished grade down to scour depths and have minimum thickness at least as large as the minimum material size. The slopes of the boulder parts of grade controls structures were set based on hydraulic considerations primarily for fish passage but also for enhanced recreational opportunities. The slopes of the riprap portions of the grade control structures were set based on the angle of repose of the material used; these sections of the grade control structures will be covered with imported alluvium to grade the body of the riffle features.

5.2.4 BOULDER ARCH STRUCTURES

Three boulder arch structures are proposed to function in series at the Dam 2 location with constructed riffles on either side of them. The boulder arch structures provide aquatic habitat diversity and improve natural aesthetic to the reach that emulates a natural rapid.

Boulder arch structures would have a diversified planform that emulates elements of rock arch designs (Aadland 2010) and Natural Channel Design W-weir structures (NRCS, 2007); each boulder arch structure would also have a downstream scour hole. Similar to W-weir structures, the boulder arches would be lower at the "bends" of the W and extend up in elevation between "bends" as a way to route flow paths and diversify flow. Additionally, drawing from Aadland (2010) rock arch designs, the boulder arches would "oscillate" opposite of the arches upstream or downstream, further increasing flow diversity, maximum pool depth and area, and enhancing fish passage, resting areas, and aquatic habitat. Lastly, the crest boulders of the arch structures would contain intermittent boulders that are raised up to 12" to add one more layer of flow diversity and benefit to fish passage. Raised crest boulder would have a minimum spacing of 2 feet with a minimum spacing of 12 feet through the lowered portions of the arch structures where the majority of downstream navigation will be routed.

Habitat boulders are proposed to be placed within the pools between boulder arches to enhance aquatic habitat diversity and fish passage. These boulders are located outside of the main flow paths through the structures and would remain submerged.

Refer to Figure 16 for a schematic of the boulder arch structures at the Dam 2 location.

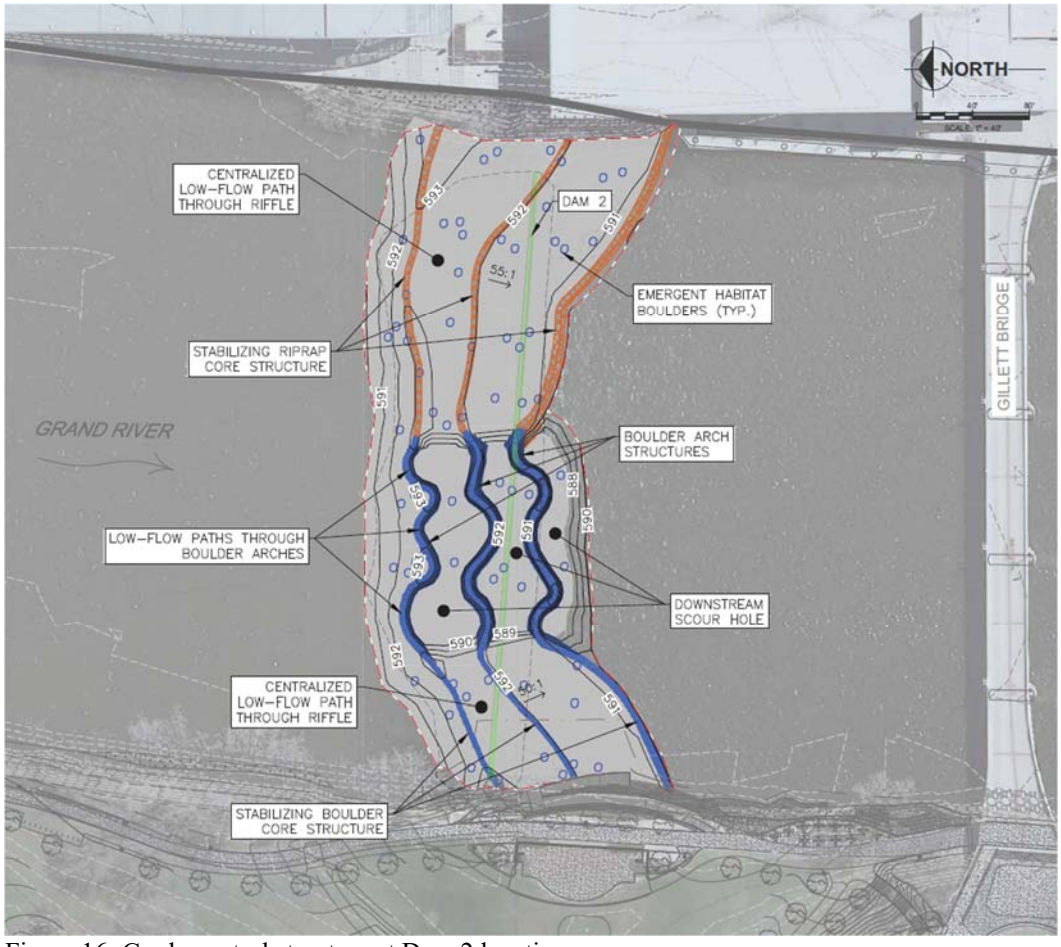

Figure 16: Grade control structure at Dam 2 location

Boulder Vane Structures

Bank vane structures would be installed at locations of existing or future public access points and would function to provide slow-moving water and hydraulic diversity at these locations. These are shown in Figure 17; two vane structures would be installed just upstream of future access points on either side of the Public Museum carousel with fine alluvium landings provided adjacent to future concrete landings at the shoreline. A vane structure would also be installed on the east side of the river where pathway improvements will be constructed as part of a separate project.

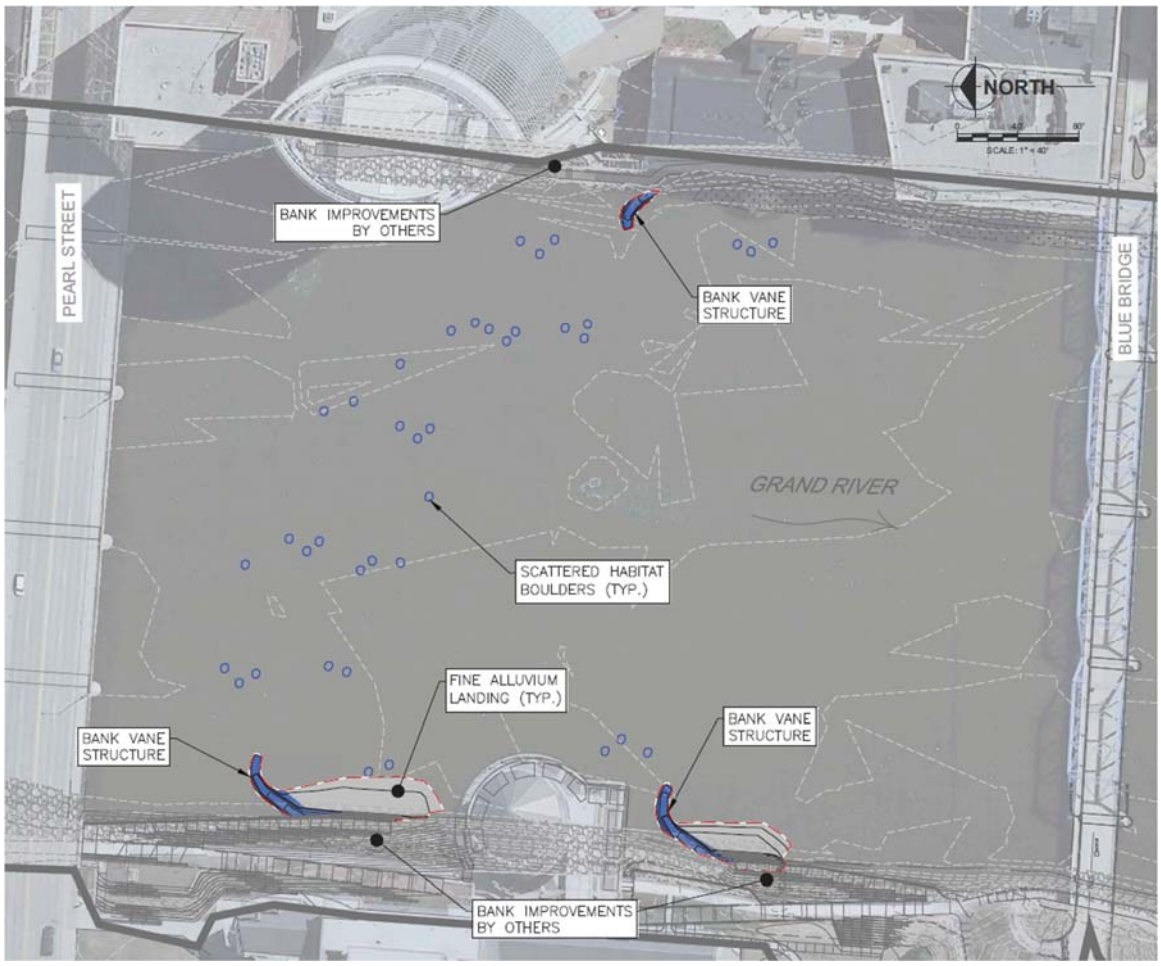

Figure 17: Bank vane structures and emergent habitat boulders

An augmented bank vane structure is proposed to be constructed between Blue Bridge and Fulton Street, adjacent to emergent habitat boulders. Refer to Figure 18. This vane structure would be extended and augmented to emulate W-weir design guidelines for habitat and natural aesthetic improvements. Scour holes would be created downstream of the structure.

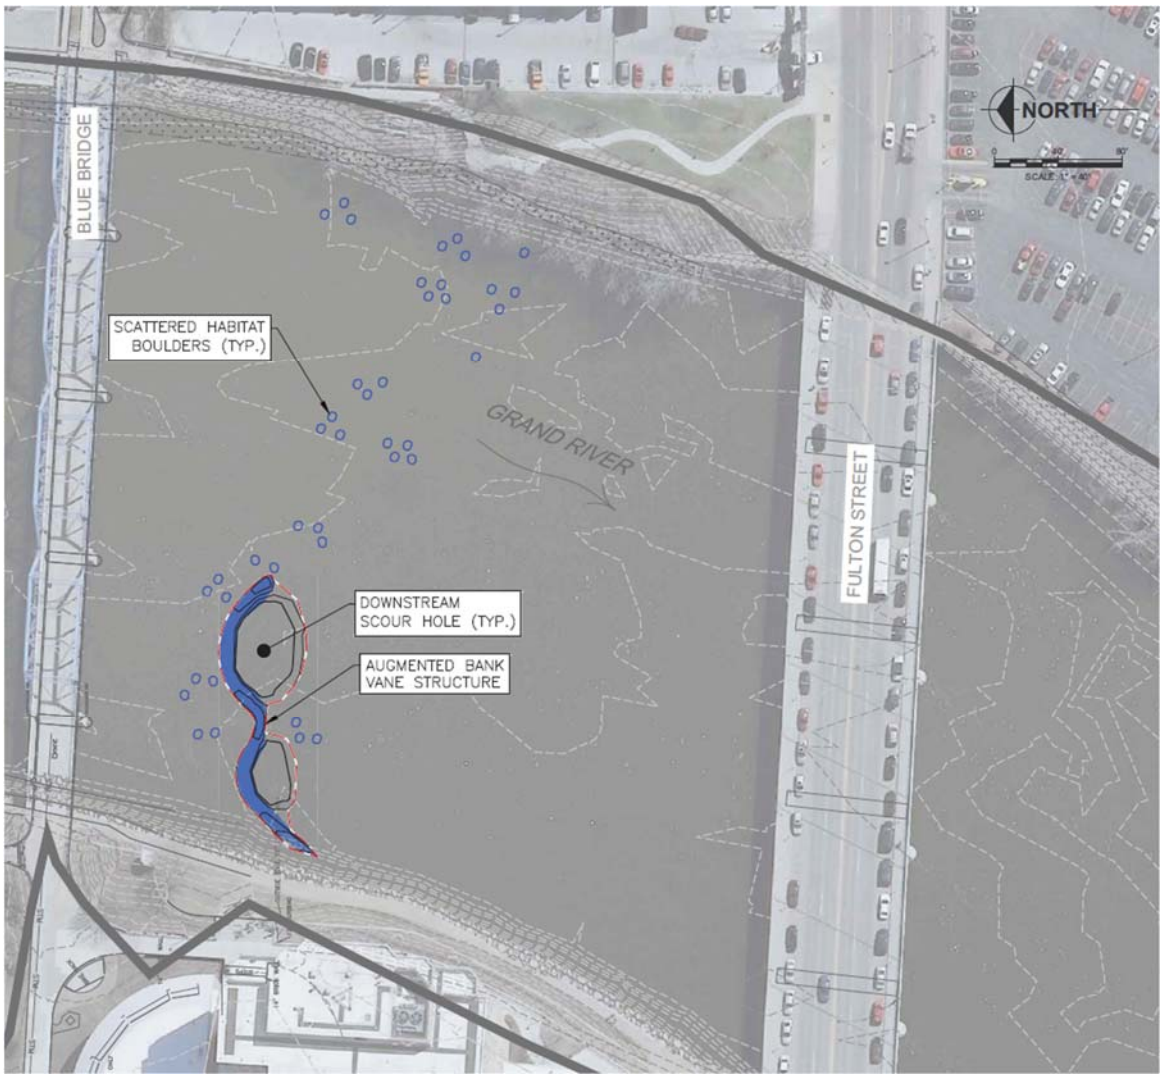

Figure 18: Augmented bank vane structure and emergent habitat boulders

5.2.5 EMERGENT HABITAT BOULDERS

Emergent habitat boulders are proposed to be placed in areas of existing riverbed to improve aquatic habitat and natural aesthetics. Depending on size and armoring of existing substrate, as determined in the field by the contractor and in coordination with the owners representative, up to half of these boulders, and at least one per cluster, would also have footer boulders installed beneath them. Refer to Figure 17 and Figure 18 for the placement of the emergent habitat boulders.

The number and configuration of the emergent habitat boulders was designed through iterative coordination with the regulatory agencies. The emergent habitat boulders would be in clusters of 1-4 boulders with each boulder separated by 4 feet minimum and each cluster separated by 12 feet minimum.

5.3 SUMMARY OF REDUCED IMPACT AREA

Through the re-design process for the project, a major focus was to avoid and minimize impacts to the existing streambed. This was one of the primary concerns expressed by EGLE through that process and was prioritized over secondary hydraulic impacts to aquatic resources. Therefore, all

revisions to the project were evaluated and designed to avoid and minimize the area of direct impact to the existing streambed, while also satisfying the framework objectives of the project. The reduction in direct impact area to the existing streambed achieved through this redesign process is presented Table 7. The expanded grading around dam removals (Alternative 2b from the previous application), which was requested by EGLE through correction requests for the previous project, has been incorporated into the current project. The total increase in impacts associated with this change was 1.7 acres and 2,400 CY of dredge. These expanded impact areas were not included in the previous project. Assuming that this area would have been added on the to previous project as well, the total reduction in direct impacts to the existing streambed for the revised project is 5.6 acres.

Table 7: Impact area comparison

Design Alternative (Alt)	Unavoidable Wetland Impact (ACRES)	Earthwork Below OHWM (CY)		Direct Permanent Impact to Existing Streambed (ACRES)	Earthwork within Floodplain[3] (CY)	
		DREDGE	FILL		DREDGE	FILL
Alt 1	0	0[1]	0[1]	0[1]	0[1]	0[1]
Alt 2b	0	4,100	3,020	4.3	1,230[4]	750[4]
Previous Project	0.01	12,880	20,020	12.7[2]	1,230[4]	750[4]
Current Project	**0.01**	**14,245**	**15,753**	**7.1**	**1,448[4]**	**724[4]**

(1) Zero earthwork for Alt 1 assumes the existing low-head dams will not need to be repaired or replaced in the next 50 years.
(2) Area includes expanded dam removal grading requested by EGLE.
(3) Volumes include associated proposed Ah-Nab-Awen Park improvements. No floodplain impacts would result from in-river improvements.
(4)Floodplain is defined here as the area above and outside of OHW, but within the 100-year flood extents.

Please refer to TOC No. 23 Cumulative Impacts for additional discussions on impacts to aquatic resources related to the Project, labeled "Lower Reach Project" in TOC No. 23.

5.4 AH-NAB-AWEN PARK IMPROVEMENTS

Proposed improvements included in this permit submittal include river access points in Ah-Nab-Awen Park from the river trail above the OHWM to the river edge below, including the construction of step access and installation of a concrete path for accessibility and equity in use and enjoyment of the river. Different locations for the improved access points were considered. Due to the existing steep wooded slopes and the location of the wetlands along much of the river frontage features in Ah-Nab-Awen Park, there are limited areas where access points could be provided with minimal impact while also allowing safe egress to and from the river. Near the concrete stage at Ah-Nab-Awen Park, there is a gradual slope into the river, without wetlands, making it a natural access point.

The first proposed access point (P11 on Design Impact Sheets [TOC No. 4]) is located at the existing concrete access ramp, which will avoid disturbing the trees and wetlands. There are no other locations in the park that will connect to the existing trail, have safe access, and avoid wetlands impacts. A second access point is also proposed to the south (P12 on the Design Impact Sheets). This additional access is necessary, as the river frontage in the proposed access ramp to the north will not be sufficient to allow additional access opportunities to the revitalized river. Therefore, the southern access point is proposed to allow for additional safe access to the river.

Multiple configurations for both access points were considered. The purpose of the access points is to allow the public to move to and from the river. The access points can only achieve this purpose below the OHWM. A landward shift away from the river would not provide safe access to the river users, as it would leave the users below the OHWM and below the wetland, but not in the flowing channel of the river.

While different options were considered, the improved access points have been designed to enhance safe, equitable access to the river by the public without causing adverse impacts to regulated resources.

5.5 BIOLOGICAL CRITERIA

The Grand River is home to a large range of aquatic species, including the endangered snuffbox mussel (*epioblasma triquerta*). Many resident fish species also inhabit the project reach, while other fish species utilize it for upstream spawning migration.

The design of the Project seeks to enhance aquatic habitat and improve the natural aesthetic of the project reach; this includes expanding the range of flow depths, magnitude and direction of flow velocity, and variability in substrate size and type. Clean, rounded, and well graded substrate is proposed, in part to provide maximum benefit to the habitat of fish, mussels, and other aquatic species. Modeling results and habitat suitability analyses indicate that the resulting river system would increase hydraulic diversity, likely improve mussel habitat, maintain or improve aquatic habitat for the large range of resident fish species, and maintain or improve the connectivity of the reach for upstream passage of resident and migratory fishes.

In addition to the habitat improvements listed above, using coarse well-graded alluvium in the construction of proposed riffle features will promote increased biological health and macroinvertebrate habitat by providing interstitial space with increased dissolved oxygen levels within the riffle features. This, combined with the hydraulics of the riffles spreading out swift velocities and avoiding sedimentation, are key to establishing a healthy macroinvertebrate habitat (DEQ, 2008).

5.6 ICE FORMATION

River-ice processes are significantly complex, not well understood, and are a function of multiple parameters contributing to ice formation, breakup, and jamming. These include local channel topography, the temperature of the streamflow, the temperature of the air, and three-dimensional river hydraulics distributions (notably mean-flow and turbulent-energy dissipation). Lai and Shen (1991) group ice formation into frazil, skim, and border ice subcategories. Kempema and Ettema (2010) elaborate on an additional subcategory of anchor ice. Each category of ice is dependent upon instream channel conditions which will vary between existing and proposed conditions. Skim ice forms at the surface of the flow and includes frazil slush pans, ice rubble, and any local surface ice. Border ice forms at the interface of structures or bedforms and the waterline, and anchor ice forms at the channel substrate. Skim ice and border ice may accumulate in certain areas to create ice bridges and channel-spanning freeze-up.

The proposed alterations are not anticipated to change the existing ice supply in sufficient quantity to affect the ice-jam mechanisms at Fulton Street Bridge, which result from breakup of the ice sheet upstream of 6th Street Dam. Any additional volume of ice generated from project actions will be negligible when compared to the continuous ice-sheet supply upstream of the project area. No areas within the downstream altered reach are anticipated to generate local ice jams at an influential scale.

5.6.0 ICE BREAK UP

The break-up of ice is a process which generates incoming floes to downstream river reaches which is critical for ice-jamming and flood concerns (Beltaos, 1997). Break-up can occur at any time when external forces exceed the critical internal strength of the ice formation. For the existing project reach, break-up of the ice sheet upstream of 6th Street Dam occurs during warming cycles, snow melt, and precipitation events. Break-up events float the upstream ice sheet over 6th Street Dam which exceeds the downstream ice transport capacity and initiates ice jams. Project actions do not influence this process or the formation of jams at Fulton Street Bridge.

5.6.1 ANCHOR ICE

Anchor ice is formed where supercooled frazil ice is driven by the current to the channel bottom and affixes to bed materials. Kempema and Ettema (2010) identified that anchor ice formation is directly related to turbulence, flow speed, ambient air temperature, and substrate characteristics. Anchor ice will not form when there is a solid ice sheet over the flow surface. Specific details regarding anchor ice formation in the Grand River under existing conditions are unknown.

The imported alluvium used to construct the riffles, as well as the boulder and riprap grade control structures have been sized to remain stable under ice formation processes in the Grand River. Sizing of these materials considered anchor ice formation and stability. Anchor ice is assumed to form in a contiguous sheet at the channel bottom; all particles at the surface maintain contact with the ice and resist buoyant rafting forces. Table 6 provides the gradations for imported alluvium. The specified d_{50} sediment size for the fine alluvium size class is 3 inches (0.25 ft). It follows to assume a one square-foot area of substrate of 0.25 ft thickness with a specific gravity of 2.65 and corresponding submerged weight of 25.7 lb/ft^3. Ice has a typical specific gravity of 0.93 with a corresponding submerged buoyant force of 4.1 lb/ft^3. Therefore, it would require approximately 6.3 ft of anchor ice thickness to mobilize the substrate (equivalency) or up to 10.0 ft of thickness to actively transport imported materials (factor of 1.5 equivalency). The calculated necessary ice thickness to mobilize and actively transport materials exceeds the typical water depths during winter months in the project reach. Therefore, anchor ice is not expected to mobilize the imported substrate.

5.6.2 BORDER ICE

Border-ice formation is a function of the exposed distance of the waterline on structures where frazil ice may accumulate. Border ice is commonly noted at bridge piers, abutment walls, and channel edges under existing conditions and contributes to the bridging freeze-up upstream of the 6th Street Dam. Empirical relationships have been proposed by Michel et al. (1982) for the formation of border ice, with stability limited by the cumulative drag force acting on the formation. Specific border-ice formations and critical hydraulics for stability are dependent upon the geometry of the river channel, seasonal variability in temperatures, and the seasonal hydrograph.

At low flows, partially exposed substrates may have benthic regions freeze up and form border ice. As flows increase, these regions will be subjective to buoyant forces which may raft substrate. Areas where the benthic sublayer may freeze up at lower flows were sized to resist mobility from border ice related rafting; however, ice thickness required to transport the proposed substrate materials is similar to the anchor ice rafting analysis described above, meaning the required thickness of ice to float and transport substrate is thicker than the expected water depths and therefore transport is unlikely to occur.

5.7 MAINTENANCE

The completed Project will be monitored per the Project's monitoring plan. Refer to TOC No. 16 Monitoring Plan. Many of the same hydrogeomorphic processes that currently require monitoring in the project reach, such as deposition of debris, sediment accumulation, and ice buildup would continue under post-project conditions. Additional areas of focus will include the project's continued ability to provide fish passage and recreational hydraulics.

The proposed grade control structures, riffles, boulder arch structures, boulder vanes, and emergent habitat boulders have been designed to remain stable under anticipated ice formation as discussed in Section 5.6. The proposed project improvements have also been designed and substrates sized to remain stable with anticipated deposition of large woody debris on the structures. Debris removal will still occur similarly to existing conditions where high flood levels carry away large debris. In the case where debris is determined to pose an immediate public safety or flood risk, the City of Grand Rapids will do so according to best management practices and seek permits as needed.

Additional information is provided in TOC No. 11 Operations, Maintenance, Repair, Rehabilitation, and Replacement (OMRRR) Report.

-- END OF SECTION 5 --

6.0 CONSTRUCTION METHODOLOGY AND ALTERNATIVES

The construction methodology, including staging, access, care of water, work isolation, and sequencing was determined through coordination with the City's construction management advisor, during which alternative means and methods were considered. Through this process, temporary impacts to the streambed, especially outside the limits of permanent impacts were avoided and minimized to the greatest extent possible.

Refer to TOC No. 9 Recommended Construction Sequencing and Methods for more detail. Also see TOC No. 10 Temporary Conditions Hydraulics Report for a more detailed description of the hydraulic analysis performed for the various stages of construction.

6.1 CONSTRUCTION STAGING

Construction staging and access is extremely limited due to the heavily developed and urban location. In many locations, particularly on the east bank, buildings and structures come right up to the edge of the floodwall. During the planning of the project, several construction staging and access locations were considered and evaluated for impacts and construction feasibility. These locations included Ah-Nab-Awen Park, 555 Monroe Ave. NW, Lacks Park, East River Edge at Fulton St., Scribner Ave. NW, and Gillett Bridge. In the end, it was determined access to the river would be most feasible and prudent from a staging area in Ah-Nab-Awen Park. Ah-Nab-Awen Park is located along the north end of the project reach. It has a large open space and connects to a major street in Grand Rapids. Additional staging and temporary stockpiling will also be made available at 555 Monroe Ave. NW; however, this site would not include construction access into the river channel. Construction staging has been identified above the OHWM. Staging will not be placed in wetlands.

6.1.0 AH-NAB-AWEN PARK

The alternatives evaluation for construction staging established Ah-Nab-Awen Park as the Project's primary construction staging and sole construction access point. The park is well-located, adjacent to most of the proposed in-channel improvements and is large enough to accommodate construction equipment and temporary material stockpiling in the opinion of the CMA. The park is City-owned and its use minimizes impacts to pedestrian use of pathways and other potential staging locations.

With Ah-Nab-Awen's open space and its gradual slope to the river, it makes this a natural entrance for the project into the river, allowing the least amount of streambed impacts due to construction access. Since a large area of the park would be disturbed during construction staging, the project also provided an opportunity for the planned improvements to Ah-Nab-Awen Park to be implemented according to the City of Grand Rapids Park's master plan. These improvements are summarized in section 5.4.

6.1.1 555 MONROE AVE. NW

The 555 Monroe Ave. NW site will be used for temporary construction staging but will not provide access to the river or impact water resources. Temporary access from 555 Monroe Ave. NW was initially considered due to it being on the east side of the river but the additional impacts to the stream bottom to provide access to the project location were not justified.

6.1.2 LACKS PARK AND GRAND RAPIDS PUBLIC MUSEUM

Access from Lack's Park, located on private property at the west end of the Blue Bridge, was originally considered due to its location at the downstream end of the project. Through the design progression process, significant concerns were voiced by the private property owner about

temporary and permanent impacts to the park. In addition, a sinkhole formed in the park in 2017, likely because of the former gypsum mines located beneath this area. As a result of objections from the property owner and public safety concerns regarding the mine, this temporary access point was removed from consideration.

6.1.3 EAST RIVER EDGE AT FULTON STREET

Access from the east edge of the river between Fulton Street and the Blue Bridge was also considered but eliminated as a potential access point due to the steep, high banks resulting in feasibility concerns with installing a functional ramp. There is also a large amount of existing mature vegetation and wetland impacts that would be realized accessing the river from this location so it was removed from consideration.

6.1.4 SCRIBNER AVE NW

Staging and access from Scribner Ave NW was considered early in the project as it was the site MDOT used during construction of the I-196 bridge expansion across the Grand River. However, due to the distance from the project location, this access point was deemed too impactful, and the benefits would not be justified. Therefore, this alternative staging and access site was eliminated.

6.1.5 GILLETT BRIDGE

Early consideration was also given to the use of Gillett Bridge for construction purposes. These purposes included potential use of hauling material in and out of Ah-Nab-Awen Park, stockpiling material on the bridge, and using a crane and barges to stage material along the river edge. The structural integrity of Gillett Bridge and its' capacity to withstand significant and repeat heavy load from construction traffic or crane was a concern to the project team.

Use of the Gillett Bridge as a construction access and staging site would temporarily close the river edge trail to the north and prevent pedestrians crossing the river at this location. Lastly, the use of this location as a staging and access point would also shut off one of the two vehicular access points into the DeVos Place parking garage.

Due to the impacts to river trail use, convention center parking, potential public safety issues because of construction equipment on the bridge, and the determination that barge work would not be feasible, the use of Gillett Bridge was eliminated from further consideration as an access/staging location.

6.1.6 SUMMARY OF CONSTRUCTION STAGING ALTERNATIVES

The alternatives analysis for construction staging resulting in two staging areas being recommended for use during construction. The primary staging area and the location of construction access will be from Ah-Nab-Awen Park and additional staging and temporary stockpiling will be made available from the 555 Monroe Ave. NW site. All other potential staging and access areas were eliminated from consideration due to additional impacts to the stream bottom, additional public safety concerns, or lack of property owner objections.

6.2 CONSTRUCTION ACCESS AND ISOLATION

Access ramps and causeways will provide routes to construction areas from the Ah-Nab-Awen Park staging area. These temporary structures have been configured to result in minimal temporary impacts to the streambed and wetlands. These impacts are shown in detail in the Design Impact Sheets [TOC No. 4]. Alternative means and methods are discussed below, along with impacts associated with construction access are described below. In all cases, equipment and

material will access the in-channel work areas through the designated staging areas via designated ramps and causeways down to the channel bed.

See the temporary care of water and staging area sheets (T sheets) in the construction plan set [TOC No. 3] for the proposed staging and access temporary work structures.

6.2.1 TEMPORARY CONSTRUCTION CAUSEWAYS AND ACCESS RAMPS

Through coordination with the construction management advisor and the regulatory agencies, several alternative means and methods for construction access were considered and evaluated. Barge access, as well as floating causeways, were considered as a way to avoid and minimize impacts to the streambed; however, this option was ruled out due to insufficient depths and velocities during the construction season. Ultimately, temporary aggregate causeways were determined as the most feasible and prudent alternative. The dimensions, including height, top width and side slopes of the causeways were minimized to what was determined necessary for construction by the construction management advisor.

Because construction staging is limited to Ah-Nab-Awen Park, it was determined the only way to safely access equipment into the work areas south of Pearl Street was to build a causeway from Ah-Nab-Awen Park.

A temporary construction causeway will also extend from the Ah-Nab-Awen Park staging area upstream to low-head dams 3 and 4. A causeway would then extend across the river downstream of each dam to provide a working pad for the demolition of the dams in the flowing channel.

Another causeway would extend from the Ah-Nab-Awen staging area down the west bank to the work areas downstream of Pearl Street and Blue Bridge. From this causeway, additional causeways would extend along Dam 1 and within the footprint of the constructed riffle at that location.

The western half of the proposed improvements at the Dam 2 location, including removal of the dam and construction of substrate enhancements, would be performed under isolated conditions. The western portion of the proposed improvements at the Dam 2 location would be accessed by causeways extending around the isolation system. Refer to the T sheets in the construction plan set [TOC No. 3] For the layout of these temporary structures.

Based on discussions with the construction management advisor, causeway and access ramp widths were determined to be 25 feet minimum with assumed 2:1 side slope and minimized to only what would be required for construction access using the existing riverbank as support where possible.

Causeways and access ramps will be composed of crushed, clean aggregate. Coarser aggregate will be used along the side slopes for erosion prevention and finer aggregate will be used for the driving surfaces.

Timber mats were considered as an alternative causeway material, but they were determined to be infeasible for use in the river due to the flow velocity and depths that would be present during construction. Stacking timber mats to necessary elevations to allow construction equipment to drive on, combined with the buoyancy of the mats resulted in this alternative being eliminated from consideration due to stability and safety concerns. However, timber mats will be used at any location where temporary impacts to wetlands cannot be avoided. The timber mats would serve as a protective layer between the aggregate causeway and the wetland.

6.2.2 WORK AREA ISOLATION

As part of the redesigned project, less of the proposed improvements were determined to require work isolation. Based on coordination with the construction management advisor, the placement of the boulder arch structures on the western half of the grade control structure at Dam 2 is the only work that was determined to require work isolation. It was the opinion of the construction management advisor and design engineer that to verify footer elevations, achieve intimate contact between boulders, and fill void spaces between boulder, to achieve the desired intent of the structure, work isolation was required for the construction of the boulder arch structures. The cofferdam structure for this isolation was chosen to be aggregate bags filled with imported sediments. Other options considered include sheet piling and aggregate cofferdams. Sheet piling was determined infeasible due to the coarse, armored nature of the streambed. Aggregate cofferdams weren't preferred due to increased impact footprint and time of installation/removal compared to the aggregate bags.

To minimize temporary impact area, the cofferdam would extend up approximately six feet and would consist of stacked three-foot aggregate bags. Due to the decreased height of the work isolation system, the work area would be inundated by the river during flow rates above approximately 3,900 cfs, which means that isolated work must occur during low flow periods, likely during July and August. The contractor would remove personnel, equipment, and loose materials prior to flooding the isolated area before the cofferdams are overtopped. Refer to the T sheets in the construction plan set [TOC No. 3] for the layout of work isolation system.

6.2.3 WORK IN WET CONSTRUCTION ACTIVITIES

All other construction, other than that described in section 6.2.2 would be performed in the wet, flowing river without work isolation. The temporary causeways would also serve as working pads to provide stable platforms with reduced flow depths. Tracking directly on the riverbed as well as long-reach excavators would be used to reach all areas of proposed improvements. These means and methods were chosen as a way to minimize temporary impact areas to the streambed as well as secondary hydraulic impacts, including potential impact to flooding or scour potential, during construction.

6.3 CONSTRUCTION SEQUENCING

Please refer to TOC No. 9 Recommended Construction Sequencing for a complete discussion of the construction sequencing for the project. This report also contains an explanation of the means and methods of dam removal during construction.

-- END OF SECTION 6 --

7.0 BASIS OF DESIGN REPORT CONCLUSION

After a decade of planning, research, and analysis, followed by a year-long re-design effort that included extensive coordination between EGLE and MDNR, the City and GRWW, and other regulatory agencies, Design Concept 4 was selected as the Preferred Project Alternative (Project) that is the subject of the City's permit application. This Basis of Design report is intended to provide EGLE with background information regarding the Project and the many steps it has taken to get here.

The City and its project partners have raised funding for this Project and acquired property rights to construct the Project. NRCS is nearing a final draft WPP-EA for the construction of this Project. And the USFWS began Formal Consultation on April 23, 2024 for the Biological Assessment submitted on March 29, 2024. A Biological Opinion concluding that the Project and its associated mussel salvage and relocation activities is not likely to jeopardize the continued existence of Snuffbox mussels is expected later in the summer of 2024.

The City and its project partners appreciate EGLE's continued collaboration over the many years that the Project was developed, and is excited to seek approval to construct a project that will have positive impacts on the public trust, riparian rights, and the environment. The City looks forwarding to securing permits under Parts 301, 303, and 31 of NREPA to bring the vision of a revitalized Grand River that everyone can enjoy to reality.

Section 1 – Introduction and Project Description

This report is intended for the Michigan Department of Environment, Great Lakes, and Energy (EGLE) and follows their Hydraulic Report Guidelines (EGLE, 2019). Section 1 describes the project and the location, Section 2 describes methods of analysis, and Section 3 summarizes the results.

This report, prepared for the City of Grand Rapids, details the harmful interference evaluation of proposed actions of the Grand River Lower Reach Project. Harmful interference is defined by EGLE (2019) as causing an increase stage or change in the direction of flow that causes, or is likely to cause: damage to property, a threat to life, pollution, impairment, or destruction of water or other natural resources.

This report is for the purpose of evaluating harmful interference under EGLE guidelines. The models developed herein are for relative comparison only.

Date of report: May 2024
Date of Topographic Data used in this report: 2007-2018

Numerous other technical reports and memorandums related to the hydraulic performance of the proposed Lower Reach Project have been prepared as part of the design. The technical reports listed below are included with the permit submittal or available upon request. Subjects addressed include (with the JPA table of contents (TOC) number in parentheses):

- Recommended Construction Sequencing Means and Methods (TOC No. 9)
- Sediment Transport Report (TOC No. 6)
- Temporary Conditions Hydraulics Report (TOC No. 10)
- Bridge Scour Report (TOC No. 7)
- Hydraulic Influence at 6th Street Dam (TOC No. 8)
- Fish Passage Report (TOC No. 14)

1.1 Project Description

The City of Grand Rapids (City) proposes to make improvements in and along the Grand River within City boundaries to improve aquatic habitat/diversity and enhance access to the river (Project). The Project

includes the demolition of four low-head dams, excavation of areas of the existing channel, and placement of coarse fill materials. The overall extents of the Project are shown in Attachment 1.

In summary, for the Project, the Grand River is proposed to be modified by:

- Demolition of four concrete low head dams
- Installation of constructed riffles and aquatic habitat structures, consisting of approximately 16,000 cubic yards of stable fill material, including boulder, riprap, and alluvium.
- Riparian shoreline improvement
- Installation of shoreline access

1.2 Watercourse and Location

The project is located on the Grand River in downtown Grand Rapids, Michigan. The Grand River Watershed is the second largest in the State of Michigan with an overall drainage area of 5,572 square miles and an elevation change of about 680 feet over about 250 miles of length. The location of the project is the approximately half-mile reach through downtown Grand Rapids, approximately 40 river miles upstream of Lake Michigan. The upstream drainage for the project location is approximately 4,900 square miles. The Grand River through the project reach has been heavily modified, including dredging and channelization (Baxter, 1891). The river is encroached by fill and concrete flood walls on the east bank. On the west bank the bank conditions vary. From Fulton Street to 6th Street Dam the bank is a vegetated and riprapped slope. The bank is formed by a concrete floodwall from 6th Street Dam to approximately 950 feet downstream of the Indian Mill Creek confluence (Fishbeck, 2020). Numerous bridges cross the river, and the majority of the bridges have three to five piers within the channel. Four concrete weirs/dams provide grade control in the river through the project reach. They vary in height from 1.5 feet to 3 feet. See photo documentation of the project reach in Attachment 14.

The Project proposes modifications to the channel bed from approximately 300 feet upstream of Bridge Street to upstream of Fulton Street Bridge. The hydraulic influence of the Project terminates upstream at the 6th Street Dam hydraulic control and downstream immediately above Fulton Street.

The low head dam just upstream of the Bridge Street bridge is the upstream extent of the Project reach and is located at the following WGS 84 Coordinates:

42.970814° N
85.674866° W

1.3 Scope of Investigation

This Hydraulics Report investigates the proposed Project on the Grand River through downtown Grand Rapids, Michigan as described in Sections 1.1 and 1.2. An alternatives analysis was performed as part of the design development process, see the Basis of Design Report included with the Joint Permit Application package for details.

1.4 Scope of Analysis

The scope of analysis for this Hydraulics Report is to evaluate the potential of proposed actions to increase water surface elevations (WSE) and energy grade line (EGL) during the 2-, 5-, 10-, 25-, 50-, 100-year flood frequency events. Proposed Conditions Model results will be compared with Corrected Effective Model WSE and EGL within the river and on the adjacent floodplain to evaluate affected properties. The threshold defined by EGLE is an increase in EGL of 0.005 ft or greater (EGLE, 2019). Exceedance of the threshold requires assessment of harmful interference, defined by EGLE as causing an increase stage or change in the direction of flow that causes, or is likely to cause: damage to property, a threat to life, pollution, impairment, or destruction of water or other natural resources (EGLE, 2019).

1.5 Existing Studies

In 2020, Fishbeck finalized the evaluation of the flood protection system through Grand Rapids on behalf of the City. This report, entitled *Grand River Flood Protection System Freeboard Evaluation Report* (Fishbeck, 2020) has been referenced for the hydraulic evaluation of the project. As part of the Federal Emergency Management Agency (FEMA) Flood Map Modernization project an updated hydraulic model created by Stantec and reviewed by Fishbeck was established as the Effective Model FEMA's National Flood Insurance Program in February 2023. This has been used as the baseline model for this hydraulic evaluation. Refer to Section 2.2.2 for more information on the Effective model.

Section 2 – Method of Analysis

2.1 Numerical Hydraulic Model

Analyses conducted in this study used HEC-RAS v.4.1 software (Brunner, 2016a). HEC-RAS is the preferred hydraulic analysis software of EGLE (EGLE, 2019). FEMA has requested that version 4.1 be used for these analyses because it was the version in which the Effective model was developed. The HEC-RAS models assume steady-state, one-dimensional open channel flow conditions. The basic computational procedure of HEC-RAS for steady flow is based on the solution of the one-dimensional energy equation. Energy losses are evaluated by friction and contraction / expansion. The momentum equation may be used in situations where the water surface profile is rapidly varied.

2.2 Hydraulic Models

2.2.2 Duplicate Effective Model (DEM)

The Current Effective Model (EM) is dated 12/2017 and became effective on February 23, 2023. This model was initially developed as part of FEMA's Flood Map Modernization Project.

The EM was obtained from FEMA and run using HEC-RAS v4.1 to create the Duplicate Effective Model (DEM). HEC-RAS v4.1 was used because this was the version originally used to create the EM. No changes were made to the flow file, geometry, or plan settings from the EM to create the DEM. The DEM HEC-RAS files are included with this report.

2.2.2 Corrected Effective Model (CEM)

The Corrected Effective Model (CEM) was created by updating the EM within the project reach. All cross sections upstream and downstream of the project reach remain identical between the EM and CEM. To generate the CEM, 11 cross sections have been added at the locations of proposed changes to the river or banks. Additionally, the CEM has incorporated more recent survey data collected for the purposes of designing the proposed enhancements. Lastly, bank elevation and levee data has been revised based on certified as built tables from the Grand River Flood Protection System Freeboard Evaluation Report (Fishbeck, 2020).

The added cross sections within the project limits were created to represent the location of proposed channel improvements at the resolution based on coordination with EGLE. In general, cross sections were added at the crests and catch lines of proposed in-channel structures which have hydraulic influence.

No physical changes or additions made to channel geometry or infrastructure since the approval of the EM were included in the CEM. The design team has not identified any physical changes to the project reach that have been made since the approval of the EM. Therefore an "existing conditions" model is not required. The CEM HEC-RAS files are included with this report.

2.2.3 Proposed Conditions Model

The Proposed Conditions model modified cross sections of the CEM, including bed elevations, blocked obstructions, and Manning's roughness, to represent the proposed project improvements.

All proposed in-stream features were modeled with multiple cross sections, including one at each invert. The Manning's roughness selected is described in Section 2.8.3. Manning's n Roughness values in locations of proposed emergent boulder were weighted to model boulders in surrounded alluvium. The four low-head dams downstream of 6th St Dam were removed from the model. These structures will be either demolished entirely from the river or cut to grade and buried so they no longer have a hydraulic effect on river flow. See the permit plans for more information on the low-head dam demolition.

Attachment 3 shows the cross sections overlain on the proposed grading areas. The HEC-RAS output for this model is included with this submittal. Attachment 10 provides a comparison of the Proposed Conditions HEC-RAS cross sections to the CEM cross sections. Detailed cross sections were created for each of the two proposed grade control structure crests.

The Proposed Condition model ties into the CEM at the upstream and downstream end of the project reach. The proposed conditions HEC-RAS files are included with this report.

2.2.4 Temporary Conditions Models

As part of a separate analysis, one-dimensional hydraulic models were developed to analyze the effects of temporary cofferdam installations on flood events in the project reach. The cofferdam will isolate portions of the river during different construction phases to allow for construction of the proposed in-channel features. Refer to the Temporary Conditions Hydraulics Report for a detailed evaluation of flood impacts during temporary construction conditions.

2.3 Horizontal and Vertical Datum

All elevations presented in this report are in the North American Vertical Datum of 1988 (NAVD-88). The use of NAVD-88 was requested by the City of Grand Rapids for consistency with the City datum.

The project was surveyed on, or projected to, the NAD 83 Michigan State Plane South Zone International Feet horizontal datum and NAVD-88. Surveyed data were GPS derived in the NAVD-88 datum using GEOID 12a with NGS benchmarks. All elevations depicted in the permit documents, including drawings and other technical reports, are in the project datum of NAVD-88.

2.4 Topographic/Hydrographic Data

Topographic and hydrographic survey data collected by RiverRestoration has been combined with data collected by FEMA and Fishbeck to establish a combined digital elevation model of the project reach and surrounding area. This combined data has been referenced to establish the model geometry for the Corrected Effective model updates to the Preliminary Effective model.

The combined existing grade surface and the proposed condition grading surfaces were developed in AutoCAD Civil 3D. Cross sections were aligned to represent the proposed bed forms in the model. Cross sections were cut from generated surfaces and exported to HEC-RAS.

2.5 Hydrology

Hydraulic analyses were performed using steady-state simulations at the 2-, 5-, 10-, 25-, 50-, and 100-year flood frequency flow rates as provided in Table 1. These flow rates were dictated through correspondence with EGLE, which is included as Attachment 2.

Table 1 – EGLE Flood Flow Rates

Recurrence Interval	**Flow (cfs)**
100-yr	50,000
50-yr	44,000
25-yr	38,000
10-yr	31,000
5-yr	26,000
2-yr	18,000
Bankfull	13,000

2.6 Extent of Model and Cross section Spacing

The Effective HEC-RAS model extends from Lake Michigan, through the project reach, and upstream of 6th Street Dam to Plainfield Township. The total length of river modeled is approximately 45 miles. The project reach begins at cross section 2121+03.5 and ends at Cross section 2147+20.8, a distance of 0.5 miles.

Cross section maps of the entire modeled reach and a zoom in of the project reach are included as Attachment 3.

A total of 41 cross sections were used to represent the project area, extending from Fulton St. upstream to 6th Street Dam, for an average cross section spacing of 64 feet, approximately 14% of the average channel width. For each feature, cross sections were placed at the downstream and upstream extent and at the crest. Additionally, cross sections were added in locations of scattered habitat boulder and bank vane structures.

Cross section locations are shown in Attachment 3. The cross sections that have been added to the HEC-RAS models to represent the changes in grading and substrate of the proposed improvements are summarized in the cross section Information Tables found as Attachment 4.

2.7 Boundary Conditions

The downstream extent of the HEC-RAS model is Lake Michigan and is represented in the flow file as a known water surface set to 579.17 feet. This boundary condition is the same for all flow rates and has been left unchanged from the Effective model. Per request from EGLE, all plans have been run under "mixed" flow regime. The upstream boundary condition for all flow rates has been set to critical depth. See Attachment 5 for the Effective water surface profile through the project reach.

Upstream and downstream boundary conditions are consistent across the Effective, Corrected Effective, and Proposed Conditions models.

2.8 Variables, Coefficients and Modeling Strategies

2.8.2 Ineffective Flow Areas and Blocked Obstructions

Overbank ineffective flow and blocked obstructions areas are consistent for the CEM and proposed conditions models and were used to represent the effects of bridge openings, floodwalls, buildings, and other structures. The CEM does not have blocked obstructions or ineffective flow areas in the main channel through the project reach. Blocked obstructions were also not used in the main channel of the proposed conditions model. Instead, proposed changes to bed elevations are represented by updates to channel geometry and emergent boulder have been modeled by implementing weighted manning n values, discussed more in the following section.

2.8.3 Manning Roughness Coefficients

EGLE is responsible under the Floodplain Authority found in Part 31, Water Resources Protection, to identify any potential increases in flood stages resulting from the Project. EGLE requested conservative Manning's *n* values be utilized such that increases to flood stages are conservatively represented by the model.

2.8.3.1 Existing Conditions (i.e., Corrected Effective)

The Manning's *n* values for the Corrected Effective Model remained unchanged from Effective Model and were not varied horizontally across the main channel, as the existing substrate is considered fairly uniform

in the river channel. At river station 212766.3 a Manning's *n* value of 0.07 was used to represent an emergent boulder in the main channel. Manning's *n* values used in the CEM are described in Table 2.

Table 2- Corrected Effective model Manning n values (as reviewed by EGLE)

Area land cover	**Manning n value**
River bottom outside of project area	0.020 – 0.040
Native Alluvium within project area	0.028 – 0.030
River Banks	0.045 – 0.080
Overbanks and floodplain	0.045 – 0.080

2.8.3.2 Proposed Conditions

Manning's *n* values were assigned to each cross section varying with material type in the Proposed Conditions Models based on WRIR 86-4127 (Blodgett, 1986) and were varied horizontally across the main channel delineated by the proposed material type as requested by EGLE. Table 10 from WRIR 86-4127 is included for reference as Attachment 6. WRIR 86-4127 was suggested as a suitable reference by EGLE staff through correspondence (EGLE, 2018).

Four material sizes are proposed to be imported and placed in the river for the project: imported fine alluvium, imported coarse alluvium, mix of MDOT plain and heavy riprap, and boulder. The Sediment Transport Report provides additional detail on how these material sizes were chosen. Manning's *n* values were assigned to each material type based on Table 10 in Blodgett (1986) per guidance from EGLE (2018). To remain conservative for analysis of more frequent flow events, a depth range associated with the 10-year event was used for determining the Manning's *n* values in the Proposed Conditions model. The 10-year event has a maximum depth of 21.5 feet, a minimum depth of 12.9 feet, and an average depth of 16.4 feet. For the 100-year event, modeled flood depths in the Grand River through the project reach are a maximum of 27.5 feet, a minimum of 19.5 feet, and an average of 22.4 feet.

Modeled Manning's *n* values for proposed substrate are summarized in Table 3 along with corresponding d_{50} particle sizes. Attachment 7 provides specifications of the imported substrate materials.

Table 3 - Proposed Conditions model Manning n values from Blodgett (1986)

Area land cover	**Manning n value**
Boulder (d_{50} = 36-48")	0.070
Mix of MDOT Plain and Heavy Riprap (d_{50} = 12")	0.055
Imported Coarse Alluvium (d_{50} = 12")	0.049
Imported Fine Alluvium (d_{50} = 3")	0.035
Native Alluvium *(same as existing)*	0.028 - 0.030
River Bottom outside of project area *(same as existing)*	0.020 – 0.040
River Banks *(same as existing)*	0.045 – 0.080
Overbanks and floodplain *(same as existing)*	0.045 – 0.080

Emergent boulders are proposed in various locations of the project, as scattered habitat boulder in native riverbed as well as in imported alluvial riffle structures. Based on coordination with EGLE in December of 2023, Manning's n values at these emergent boulder locations were weighted based on total width of boulder, projected onto the cross sections. Emergent Boulder weighted Manning roughness values are summarized in Table 4. Manning's roughness information for each cross section is found in the cross section Information Tables found in Attachment 4. Manning's *n* values for unmodified sections and overbanks were left unchanged from the values used in the CEM and EM.

Table 4: Weighted Manning n values at locations with emergent boulder

Cross section	Total flow width of boulder (ft)	Total flow width of alluvium (ft)	Alluvial material	Weighted value
2122+50	87.5	167.5	Existing bed, n = 0.03	0.0437
2127+06.3	11.2	393.9	Existing bed, n = 0.028	0.0292
2127+66.3	11.5	192.9	Existing bed, n = 0.028	0.0304
2128+77.2	51.1	154.6	Existing bed, n = 0.028	0.0384
2129+80.5	38.8	144.9	Existing bed, n = 0.028	0.0369
2133+00	123.4	308.8	Imported riprap, n = 0.055	0.0593
2143+99.5	150	303.7	Existing bed, n = 0.028	0.0419

2.8.4 Contraction and Expansion Coefficients

Contraction and Expansion (C&E) coefficients are utilized in HEC-RAS to represent minor losses caused by floodplain contractions and expansions through structures such as culverts and bridges. C&E coefficients were set in the Effective Model based on standard engineering practice, using 0.1 and 0.3 for most cross sections and higher coefficients for approach and departure sections of bridges and other large obstructions in the floodplain or river (USACE, 2016). The 100-year floodplain and active flow channel is contained entirely in the floodwalls through the project reach, so there is minimal contraction or expansion through the bridges compared to a classic example of a smaller opening created by bridge approaches spanning a larger floodplain. Expansion and contraction coefficient information for each cross section is found in the cross section Information Tables found in Attachment 4.

2.8.5 Flow Regime

All flow rates for the Duplicate Effective, Corrected Effective, and Proposed Conditions HEC-RAS models were modeled assuming a mixed flow regime with the boundary conditions summarized in Section 2.7. Sub-critical flow is a conservative estimate of flow depths during these flood events which can be greater than 20 feet with Froude Numbers typically between 0.1 and 0.5.

2.8.6 Bridge Modeling Approach

Bridge modeling approaches, variables and other assumptions are unchanged from the Effective model. All Bridges in the project used the same low flow modeling approach, taking the highest energy answer of the energy equation, momentum equation and the Yarnell equation. Pier coefficients ranged from 1.0 to 1.5 for the momentum equation and 0.9 to 1.15 for the Yarnell equation. For high flow scenarios, bridges whose low chord was submerged were modeled as pressure/weir flow. The remaining bridges in the HEC-RAS model were high flow modeled as energy only. Default values were used for the submerged inlet and

outlet coefficients. The bridge modeling approaches were kept the same for all HEC-RAS models used in the project analysis.

Attachment 8 lists the modeling approach and coefficients used for each bridge in the project reach.

2.8.7 Weir Discharge

There are five in-line structures in the EM and CEM HEC-RAS models, the four low head dams in the project reach and the 6th Street Dam. When present in the modeled scenario, all dams are modeled identically in all project models and have remained unchanged from the EM. The four low head dams have been removed from the Proposed Conditions models and replaced with cross sections representing the proposed channel improvements. The proposed in-channel features are in general wide and gently sloping. Modeling these proposed features as in-line structures in HEC-RAS would not be appropriate. Table 5 summarizes the relevant paraments for each in-line structure.

Table 5 – In-line structure modeling parameters

Structure	River Sta	Weir Crest Shape	Width	Weir Coefficient
Low-head Dam #1	2132+16.5	Broad Crested	5	3.2
Low-head Dam #2	2138+54.3	Broad Crested	3.3	3.2
Low-head Dam #3	2143+96.4	Broad Crested	4.2	3.2
Low-head Dam #4	2147+16.2	Broad Crested	7.3	3.2

Section 3 - Modeling Results

3.1 Duplicate Effective Model Comparison to Corrected Effective Model

The 100-year Water Surface Elevation (WSE) of the Duplicate Effective Model was compared to the 100-year WSE with the Corrected Effective model. The addition of 11 cross sections (see Section 2.6) through the project reach results in locations of increased calculated water 100-yr water levels within the project reach and extending up to 6th Street Dam. The maximum increase was calculated to be 0.02 feet downstream 6th Street Dam. Calculated increases in 100-yr water levels upstream of 6th Street Dam are 0.01 feet directly upstream of the dam and gradually decrease to 0.00 feet at the upstream extent of the model. Water surfaces downstream of the project reach are identical between the two models. Figure 1 compares 100-yr water surface profiles for the DEM vs CEM.

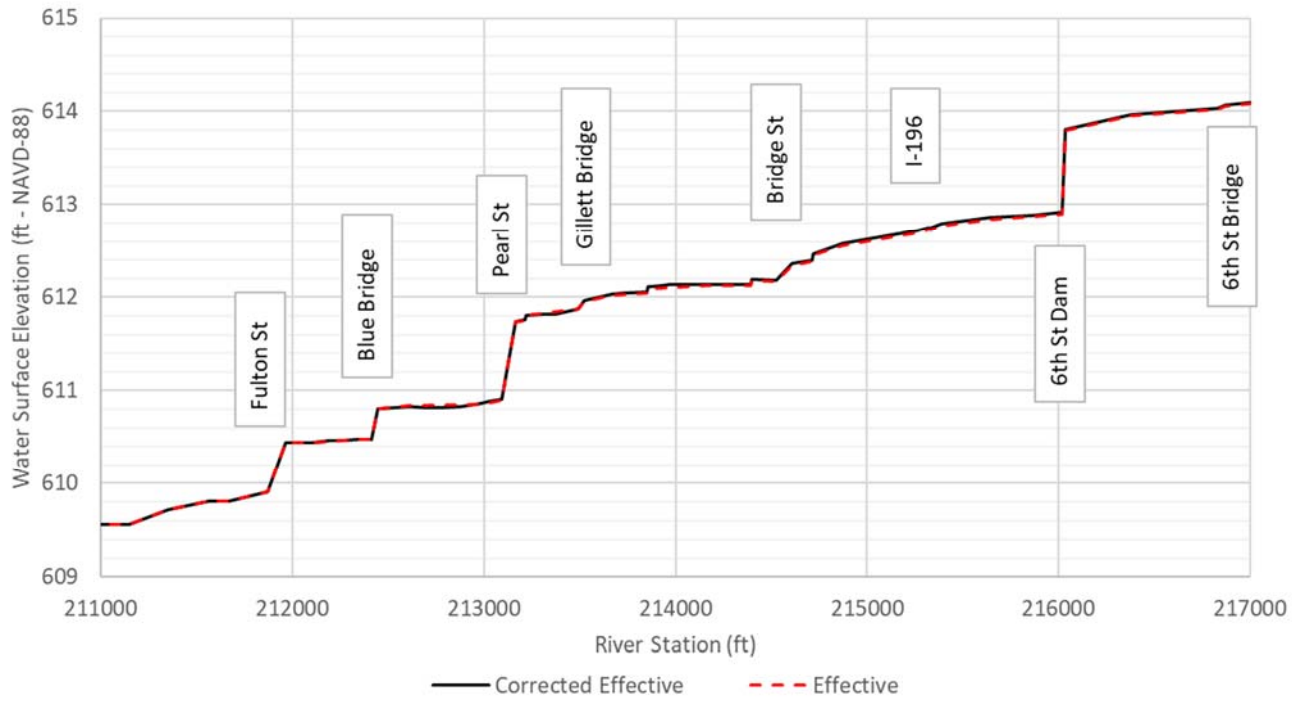

Figure 1 – Duplicate Effective model compared to Corrected Effective model (100-yr Flow Event)

3.2 Corrected Effective vs Proposed Conditions

Tabular modeling results for the WSE and EGL of the Corrected Effective and Proposed Conditions models, as well as comparisons between the two models, are presented in Attachment 11. Profile plots of the WSE and EGL for each flow event are provided in Attachment 12. Planimetric extents of the inundation limits for the 2-yr, 5-yr, 10-yr, 25-yr, 50-yr, and 100-year are provided in Attachment 9.

Table 6 and Figure 2 compares the Corrected Effective model to the Proposed Conditions model for the 100-year flow event. The cross sections included in the table and figure correspond to the channel between Fulton St. Bridge and the 6th Street Bridge, which includes the entire project reach. Small increases in 100-yr water surface elevation were calculated within the project reach. These increases, ranging between 0.01 – 0.05 ft (0.1 - 0.6 inches), all remain within the flood protection system and are being addressed through a CLOMR process with FEMA. The CLOMR will address rises modeled in the CEM (discussed in Section 3.1) and Proposed Conditions. FEMA and EGLE have agreed that the CLOMR and State permit review process will happen concurrently.

The tables in Attachment 11 and the profiles in Attachment 12 also show the modeling results for flows less than the 100-year event. For these smaller flow events, there are water surface increases in the reach between Fulton St Bridge and the 6th Street dam. The largest increases are for the lowest modeled flow events; the 2-year increases are 0.27 ft maximum and 0.07 ft average. As is shown in the Attachment 12 profiles, all increases are contained within the floodwall system and City of Grand Rapids easements and do not cause harmful interference. There are some private property owners adjacent to the flood

protection system between Fulton St Bridge and the I-196 Bridge. Attachment 13 includes a table of each adjacent property and the adjacent calculated increase in water surface for each flow rate.

Although reductions in water levels are calculated at the downstream cross section of 6th Street Dam (RS 2160+20.2), 25-year flood modeling results show rounding adjustments within the model at a few isolated cross sections upstream of the dam result in 0.01' increases being shown in the HEC-RAS results tables when set to round to two decimal places. These small increases seem to be a result of inconsistencies in the HEC-RAS calculations and cannot be explained hydraulically, given the lower tailwater elevations calculated at 6th Street Dam. Three decimal places have been reported in the Attachment 11 tables where these inconsistencies occur. Given that the tailwater elevation is lower during these flow rates and subcritical flow is present, these rounding adjustments are not an actual hydraulic concern.

Table 6 – Comparison of Calculated 100-yr Water Surface Elevation (WSE): Corrected Effective comparison to Proposed Conditions

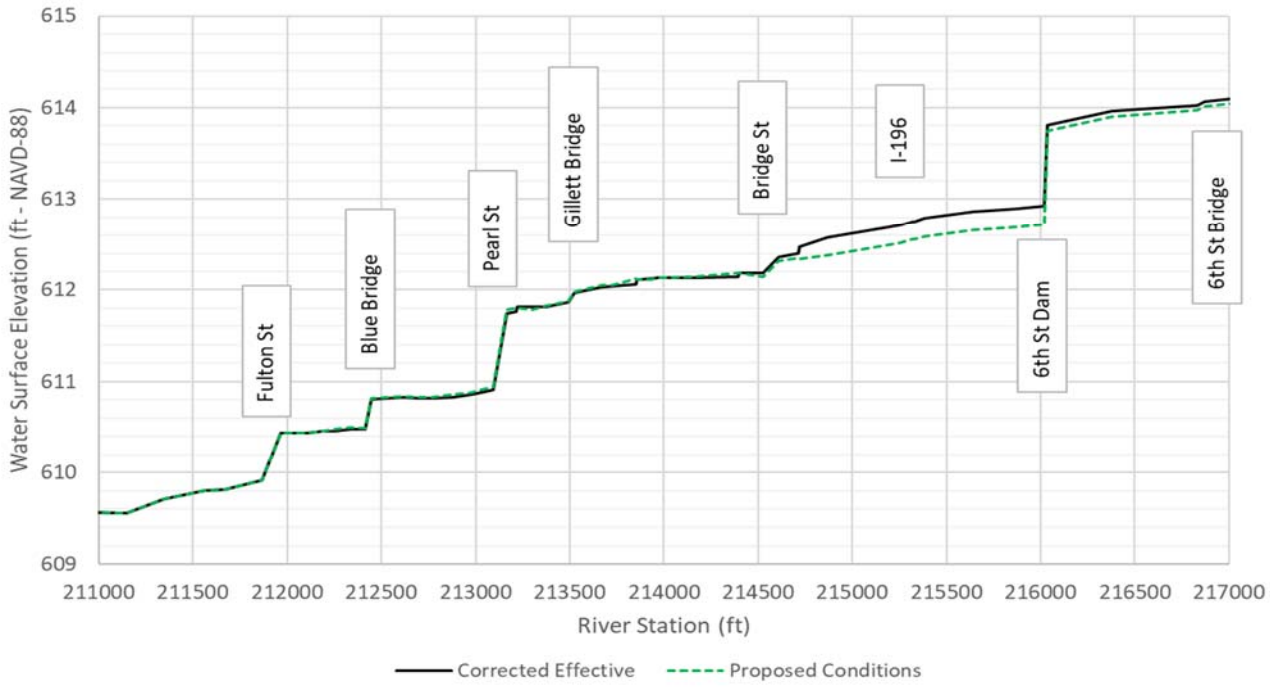

Figure 2 – Corrected Effective compared to Proposed Conditions (100-yr Flow Event)

The increases in modeled base flood elevation compared to the EM are being addressed in a Conditional Letter of Map Revision (CLOMR) that will be developed by the project team and submitted to FEMA as part of the project's permitting process.

3.3 Floodway Analysis

All fill associated with the project is located in the main channel of the Grand River, within the current Effective Floodway boundaries and within the City's flood protection system. A floodway evaluation is being completed as part of the CLOMR review FEMA has requested; any potential revisions to the Floodway boundaries will be discussed through that CLOMR process.

3.4 Conclusion

It is the opinion of the engineer, Scott Prins (RiverRestoration.org, LLC), that based on the hydraulic modeling results and analysis presented herein, the proposed project does not create a harmful interference as defined in the EGLE Hydraulic Report Guidelines (EGLE, 2019) as "causing an increase stage or change in the direction of flow that causes, or is likely to cause: damage to property, a threat to life, pollution, impairment, or destruction of water or other natural resources".

The proposed conditions model calculates modeled increases of up to 0.05 ft within the project reach. However, increases do not extend upstream or downstream of the project and remain within the City's flood protection system. A CLOMR request details these changes to the 100-yr flood profile and is being reviewed by FEMA. Increases in water surface elevations are present for the 2- through 50-year flood events, but the increases are also contained within the City of Grand Rapids' flood projection system and do not result in Harmful Interference as defined by EGLE.

Section 4 – Abbreviations

Crit W.S. – Critical water surface elevation

E.G. Elev – Energy Grade Elevation

E.G. Slope – Energy grade slope

EGL - Energy Grade Line

HGL – Hydraulic Grade Line

Min Ch El – Minimum channel elevation

Q Total – Total Discharge of water flow

Vel Chnl – Average velocity of flow in the channel

W.S. Elev (WSE) – Water Surface Elevation

WSE – Water Surface Elevation

RE: flood or low flow discharge request (ContentID - 168812)

GL -wrd-qreq <GL -wrd-qreq@michigan.gov>

Thu 3/24/2022 5:37 PM

To: Scott Prins <scott.prins@riverrestoration.org>

We have processed the discharge request submitted by email on March 11, 2022 (Process No. 20220143), as follows:

Grand River at 6th Street Dam, Section 24, T7N, R12W, City of Grand Rapids, Kent County, has a total drainage area of 4637 square miles and a contributing drainage area of 4531 square miles. The 50%, 20%, 10%, 4%, 2%, 1%, 0.5%, and 0.2% chance peak flows are estimated to be 18000 cubic feet per second (cfs), 26000 cfs, 31000 cfs, 38000 cfs, 44000 cfs, 50000 cfs, 57000 cfs, and 65000 cfs, respectively. (Watershed Basin No. 14 Grand).

Please include a copy of this letter with your application for permit. These estimates should be confirmed by our office if an application is not submitted within one year. If you have any questions concerning the discharge estimates, please contact Ms. Susan Greiner, Hydrologic Studies and Floodplain Management Unit, at 517-927-3838 or by email to GreinerS@michigan.gov. Any questions concerning the hydraulics or the proper procedure for filing for a permit should be directed to Mr. Jacob Patin, Water Resources Division, Grand Rapids District Office, at 616-204-7176 or email to PatinJ1@michigan.gov.

Low flows are provided in a separate email.

NOTES TO USERS

For information and questions about this Flood Insurance Rate Map (FIRM), available products associated with this FIRM, including historic versions, the current map date for each FIRM panel, how to order products, or the National Flood Insurance Program (NFIP) in general, please call the FEMA Map Information eXchange at 1-877-FEMA-MAP (1-877-336-2627) or visit the FEMA Flood Map Service Center website at https://msc.fema.gov. Available products may include previously issued Letters of Map Change, a Flood Insurance Study Report, and/or digital versions of this map. Many of these products can be ordered or obtained directly from the website.

Communities annexing land on adjacent FIRM panels must obtain a current copy of the adjacent panel as well as the current FIRM Index. These may be ordered directly from the Flood Map Service Center at the number listed above.

For community and countywide map dates refer to the Flood Insurance Study Report for this jurisdiction.

To determine if flood insurance is available in this community, contact your Insurance agent or call the National Flood Insurance Program at 1-800-638-6620.

Base map information shown on this FIRM was provided in digital format by multiple agencies. The following sources provided base data: Kent County, Michigan, the United States Geological Survey (USGS), the United States Department of Agriculture (USDA), and the Center for Shared Solutions and Technology Partnerships. Imagery was provided in digital format by the United States Department of Agriculture, dated 2016, and has a 1-meter ground resolution.

NON-ACCREDITED LEVEE SYSTEM: This panel contains a levee system that has not been accredited and is therefore not recognized as reducing the 1-percent-annual-chance flood hazard.

Relationships used in preparing table:

Equation 12 $$n = \frac{0.0926\, d_a^{0.167}}{0.794 + 1.85 \log d_a/D_{50}} \quad \text{for } 1.5 < d_a/D_{50} < 185$$

Equation 17 $$n = 0.0185 d_a^{0.167} \quad \text{for } 185 < d_a/D_{50} < 30{,}000$$

ATTACHMENT 7:
IMPORTED SUBSTRATE SPECIFICATIONS

IMPORTED BOULDERS SPECIFICATION

Imported Boulders may be quarried or excavated and generally smooth in shape with the largest rock faces being approximately flat. Boulders shall be of a consistent material for the entire project and shall be a color that is aesthetically neutral with the native landscape. Boulder gradations shall conform to Table 1 by number, and measurement of the intermediate axis ("B"-Axis). The minor axis (shortest dimension or "C"-Axis) shall not be less than indicated in Table 1. Boulders exposed in the grade controls and keyed into the toe of each structure shall have a minimum intermediate axis (B-Axis) of 48 inches.

Table 1. B-Axis Rock Gradations (inches)

Percent of Stones	Indicator	24 inch	36 inch	48 inch	60 inch	72 inch
< 10%	Greater	36	48	60	72	84
> 75%	Between	32&18	42&30	54&36	66&	78&60
0%	Less	15	21	28	38	48
C-Axis	Greater	10	15	20	25	30

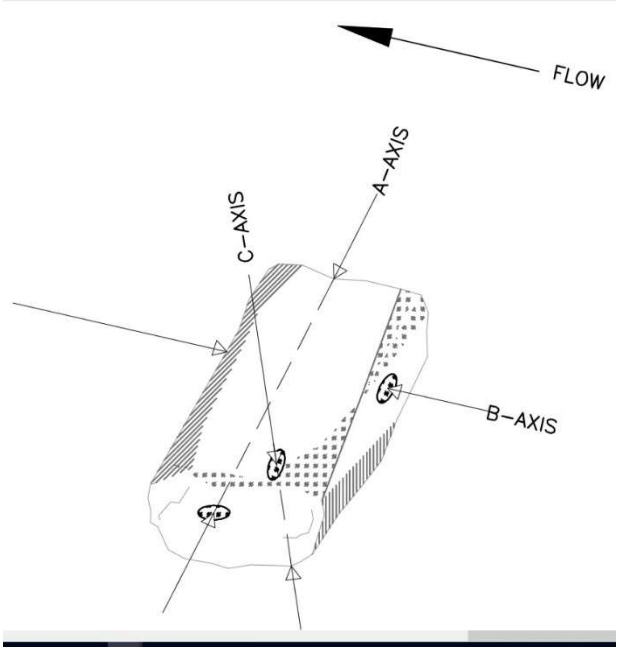

Figure 1. Dimensional axes of a boulder

Natural Boulders shall consist of hard, dense durable stone, resistant to weathering. Surface stones must have an aesthetic, neutral color and be consistent material throughout the project unless specified in plans. Stone shall be suitable for incidental human contact. CONTRACTOR shall submit source information and samples to ENGINEER. Erratic boulders in the lower peninsula of Michigan that have been subjected to weathering such as glacial or alluvial flows will be preferred and may be approved by Engineer based on visual inspection.

The Engineer may require the Contractor to furnish laboratory results if, in the Engineer's opinion, the material is marginal or unacceptable. At the request of the Engineer, the Contractor shall furnish laboratory test results indicating that the material meet the requirements including those for abrasion resistance and soundness as indicated below:

---Boulders shall have a minimum specific gravity of 2.65.

---Abrasion resistance by Los Angeles Machine; Test Method ASTM C535; Specification Requirement: 20% loss, maximum.

--Soundness by use of Sodium/Magnesium Sulfate, Test Method ASTM D5240-04 Standard Test Method for Testing Rock Slabs to Evaluate Soundness of Riprap by Use of Sodium Sulfate or Magnesium Sulfate; Specification Requirement: 5% loss, maximum.

--Soundness by Freezing and Thawing, Test Method ASTM D5312-04 Standard Test Method for Evaluation of Durability of Rock for Erosion Control Under Freezing and Thawing Conditions; Specification Requirement: 5% loss, maximum.

Figure 2. Glacial run natural boulders 48-inch gradation

IMPORTED ALLUVIUM MATERIAL

The Project will utilize two size classes of imported alluvium: Coarse Alluvium and Fine Alluvium. Coarse Alluvium shall be used for in-river construction of riffle structures and Fine Alluvium shall be used in specified locations on plans. Both gradations may be used to backfill voids within boulder and riprap structures. Imported Alluvium shall consist of clean, hard, durable, rounded, and well graded material. Imported Alluvium may be screened or crushed material. Unless specified in drawings, gradations shall match those detailed in Table 2. Materials shall meet the following specification requirements.

---Minimum specific gravity of 2.55.

---Abrasion resistance by Los Angeles Machine; Test Method ASTM C535; Specification Requirement: 28% loss, maximum.

--Soundness by use of Sodium/Magnesium Sulfate, Test Method ASTM D5240-04 Standard Test Method for Testing Rock Slabs to Evaluate Soundness of Riprap by Use of Sodium Sulfate or Magnesium Sulfate; Specification Requirement: 10% loss, maximum.

--Soundness by Freezing and Thawing, Test Method ASTM D5312-04 Standard Test Method for Evaluation of Durability of Rock for Erosion Control Under Freezing and Thawing Conditions; Specification Requirement: 10% loss, maximum.

Glacio-fluvial erratic materials deposited in the lower peninsula of Michigan may be approved by Engineer upon visual inspection.

Table 2. Coarse and Fine Alluvium Material Gradations (inches)

By weight	Indicator	Coarse Alluvium	Fine
100%	Passing	30”	8"
60%-85%	Passing	20”	6"
35%-65%	Passing	12”	3"
25%-55%	Passing	8”	1.5"
15%-35%	Passing	4”	3/4”
0%-5%	Passing	1.5”	1/5”
	D_{85}	18”	6"
	D_{50}	12”	3"
	D_{30}	4”	3/4”

Figure 2. Example of suitable alluvium material

IMPORETED RIPRAP MATERIAL

Riprap shall be used as shown in plans to form the stabilizing core and toes structures of the constructed riffles as well as the toe backfills at dam removal locations as shown on plans.

Riprap materials should comply with the 2012 Michigan Department of Transportation (MDOT) Standard Specifications for Construction, Section 916 – Erosion and Sedimentation Control with the following exceptions:

1. Only natural stone is permitted. Solid precast concrete blocks and sound pieces of broken concrete are not permitted. No reinforcing steel is permitted.
2. Riprap Substructure shall consist of 50 percent (by volume) MDOT spec Plain Riprap and 50 percent (by volume) MDOT spec Heavy Riprap. The Contractor is permitted to mix the two size classes on site with equipment. The resulting mix shall be a well-mixed gradation with a D50 of 12 inches.

Construction and installation of Riprap should comply with the 2012 Michigan Department of Transportation (MDOT) Standard Specifications for Construction, Section 813 – Slope Protection with the following exceptions:

1. Geotextile liner is only needed where shown on plans along banks. Geotextile liner is not required beneath riprap substructure places on the horizontal plane of the channel bed.
2. Riprap will be placed in the horizontal plane of the channel as shown in the plans in horizontal individual lifts not to exceed 30 inches, backfilling with alluvium between lifts. Placement of riprap shall maintain intimate contact between riprap material within matrix of rock.
3. Riprap placed along banks will be placed as shown in the plans and in accordance with MDOT Standard Specifications for Construction, Section 813.

Figure 3. Imported riprap example

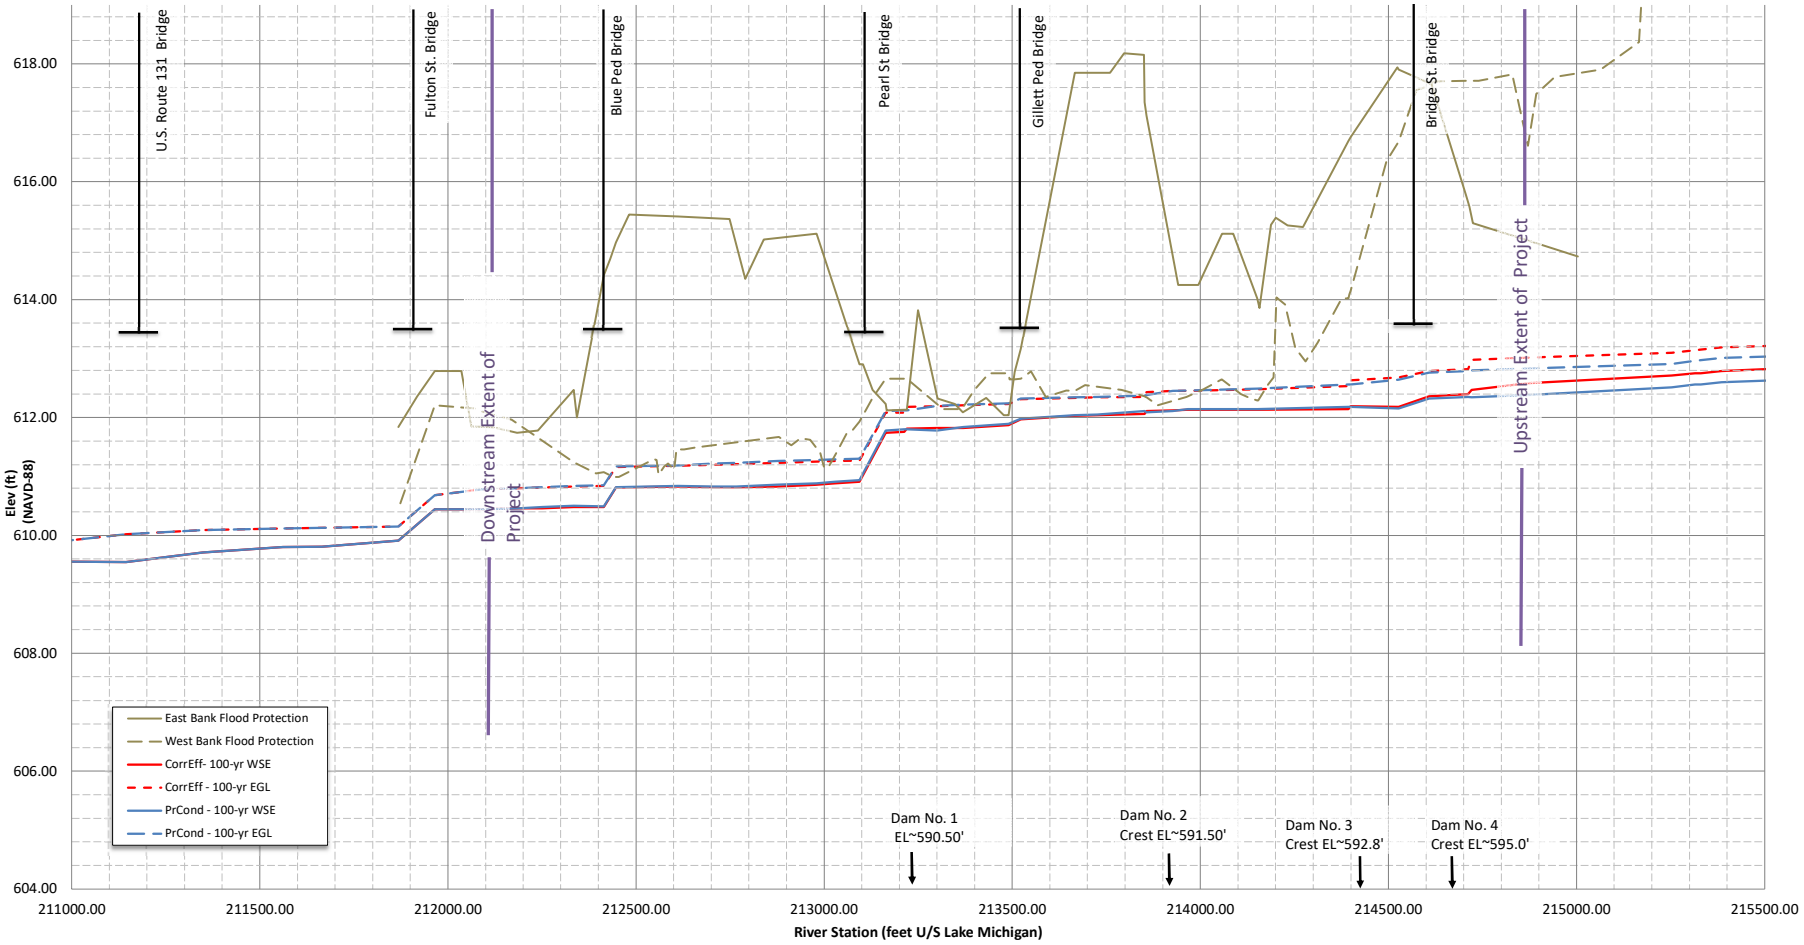
HYDRAULIC MODEL – WSE AND EGL PROFILES

Attachment 12

100-yr Flood Modeling Results - Hydraulic and Energy Grade Line
STA 211+000 to 214+500

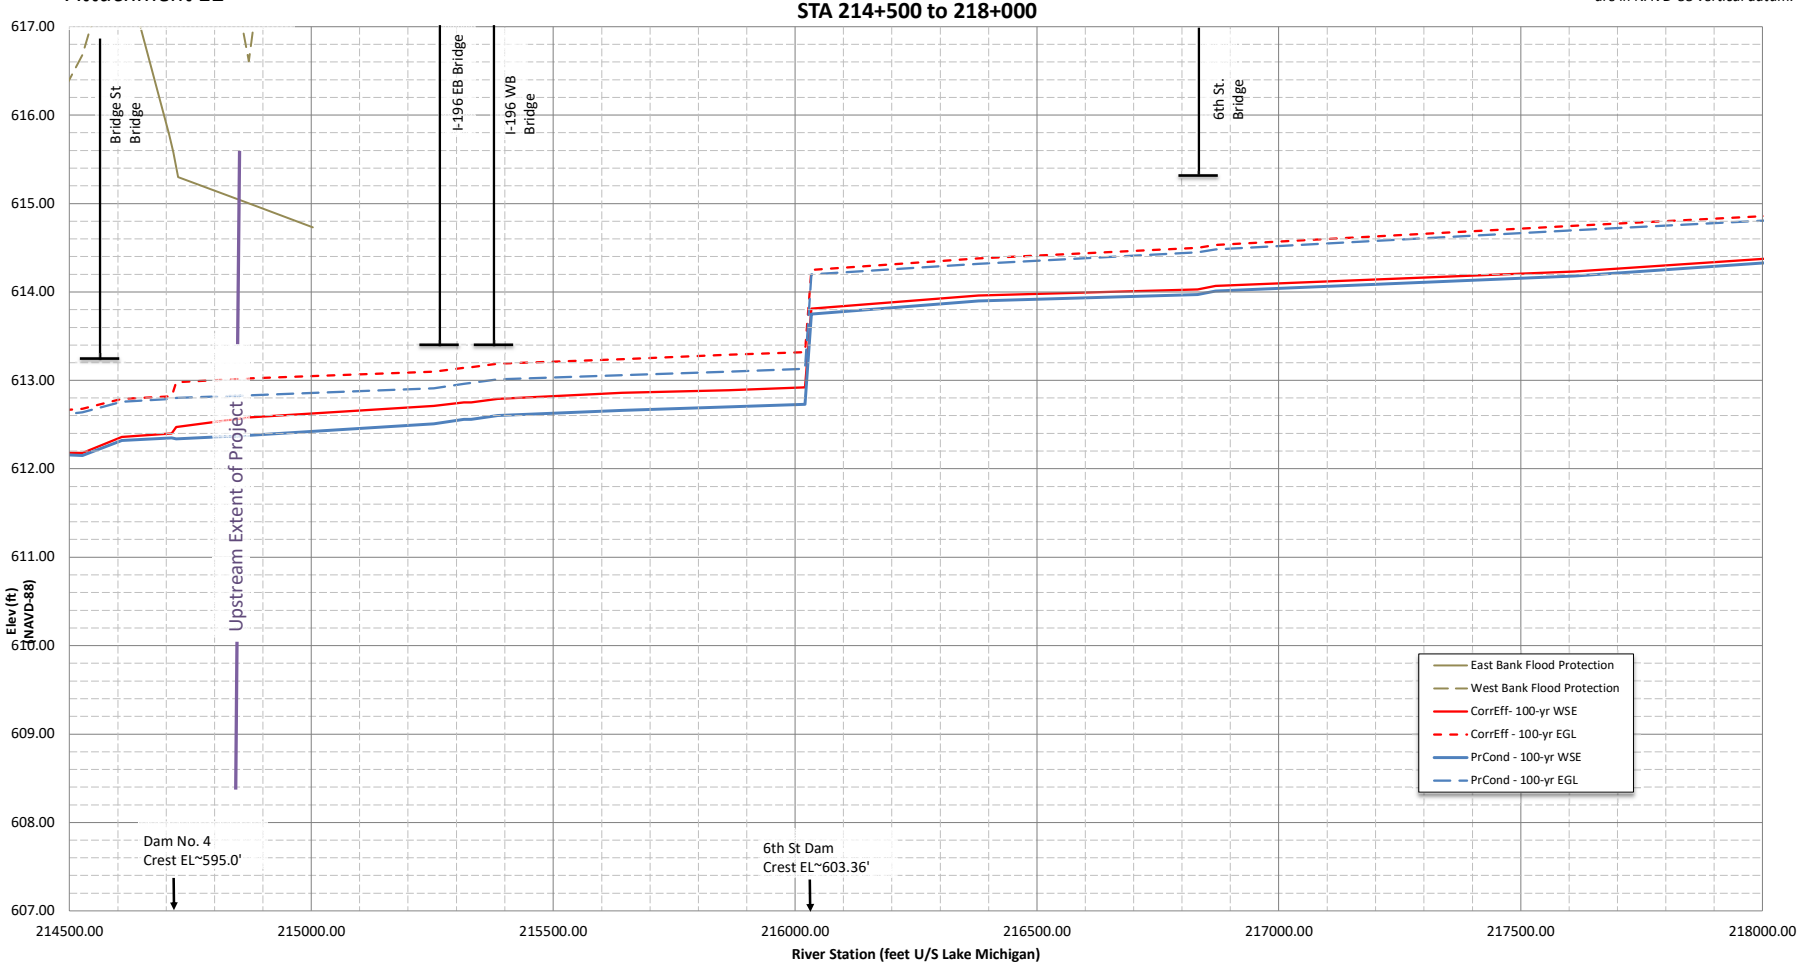
All elevation shown in this chart are in NAVD-88 vertical datum.



Attachment 12

100-yr Flood Modeling Results - Hydraulic and Energy Grade Line
STA 214+500 to 218+000

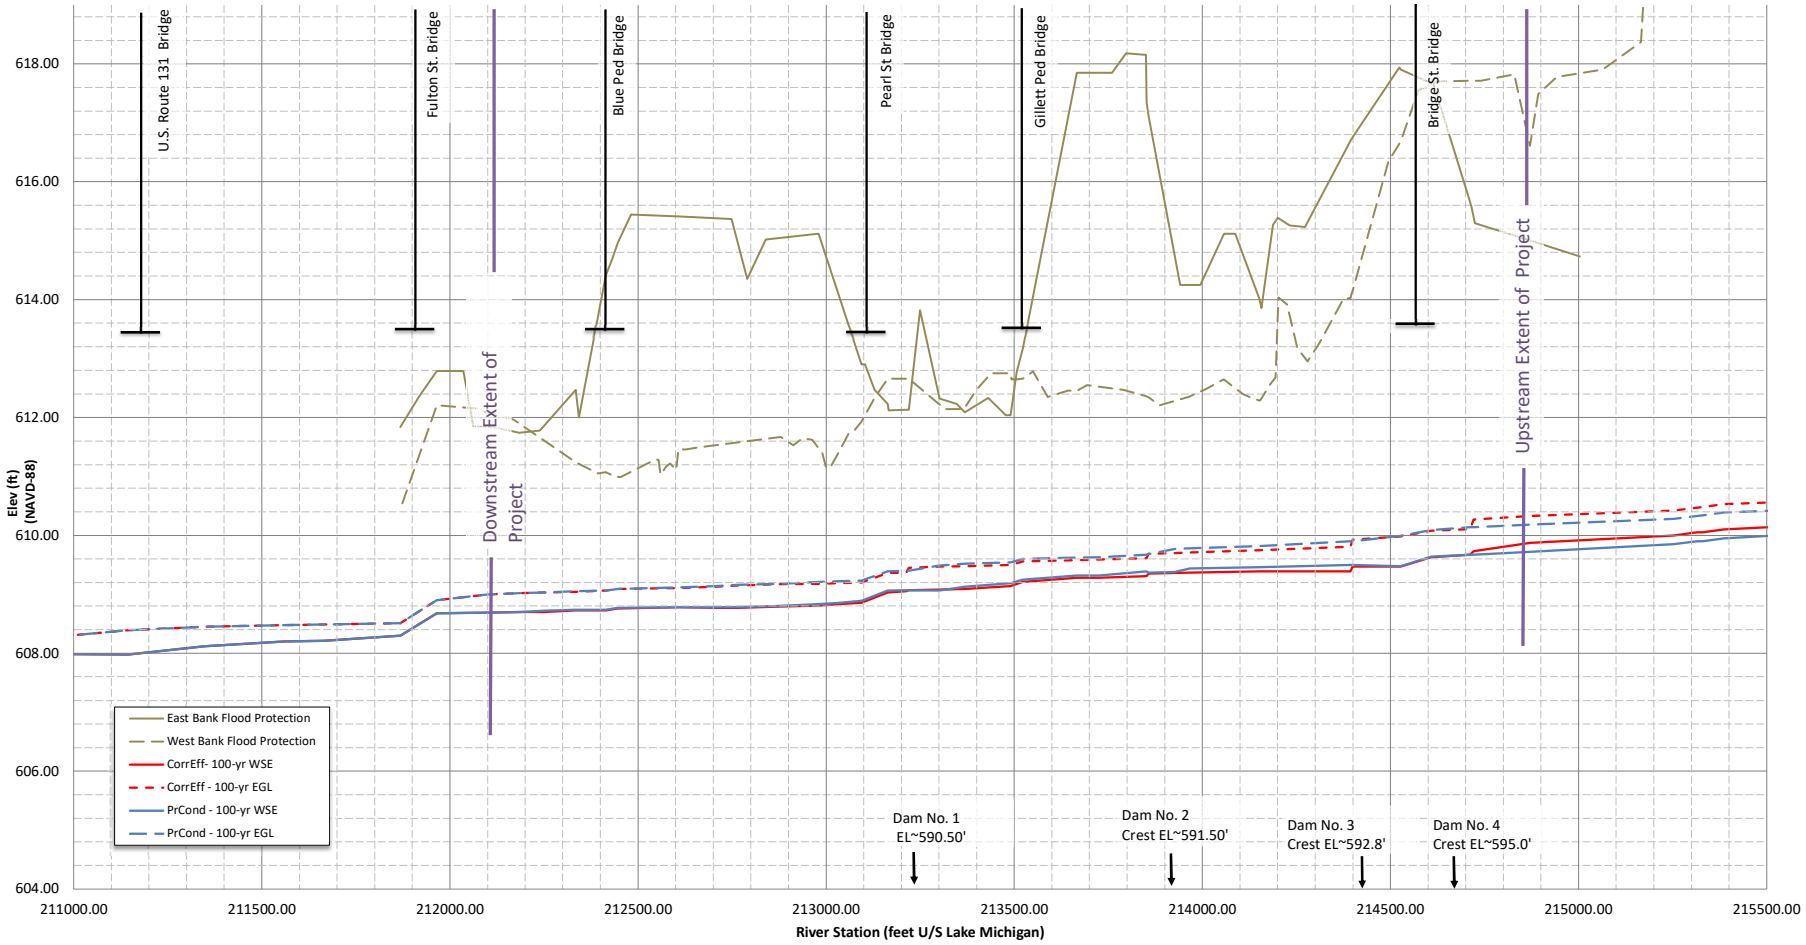
All elevation shown in this chart are in NAVD-88 vertical datum.



Attachment 12

50-yr Flood Modeling Results - Hydraulic and Energy Grade Line
STA 211+000 to 214+500

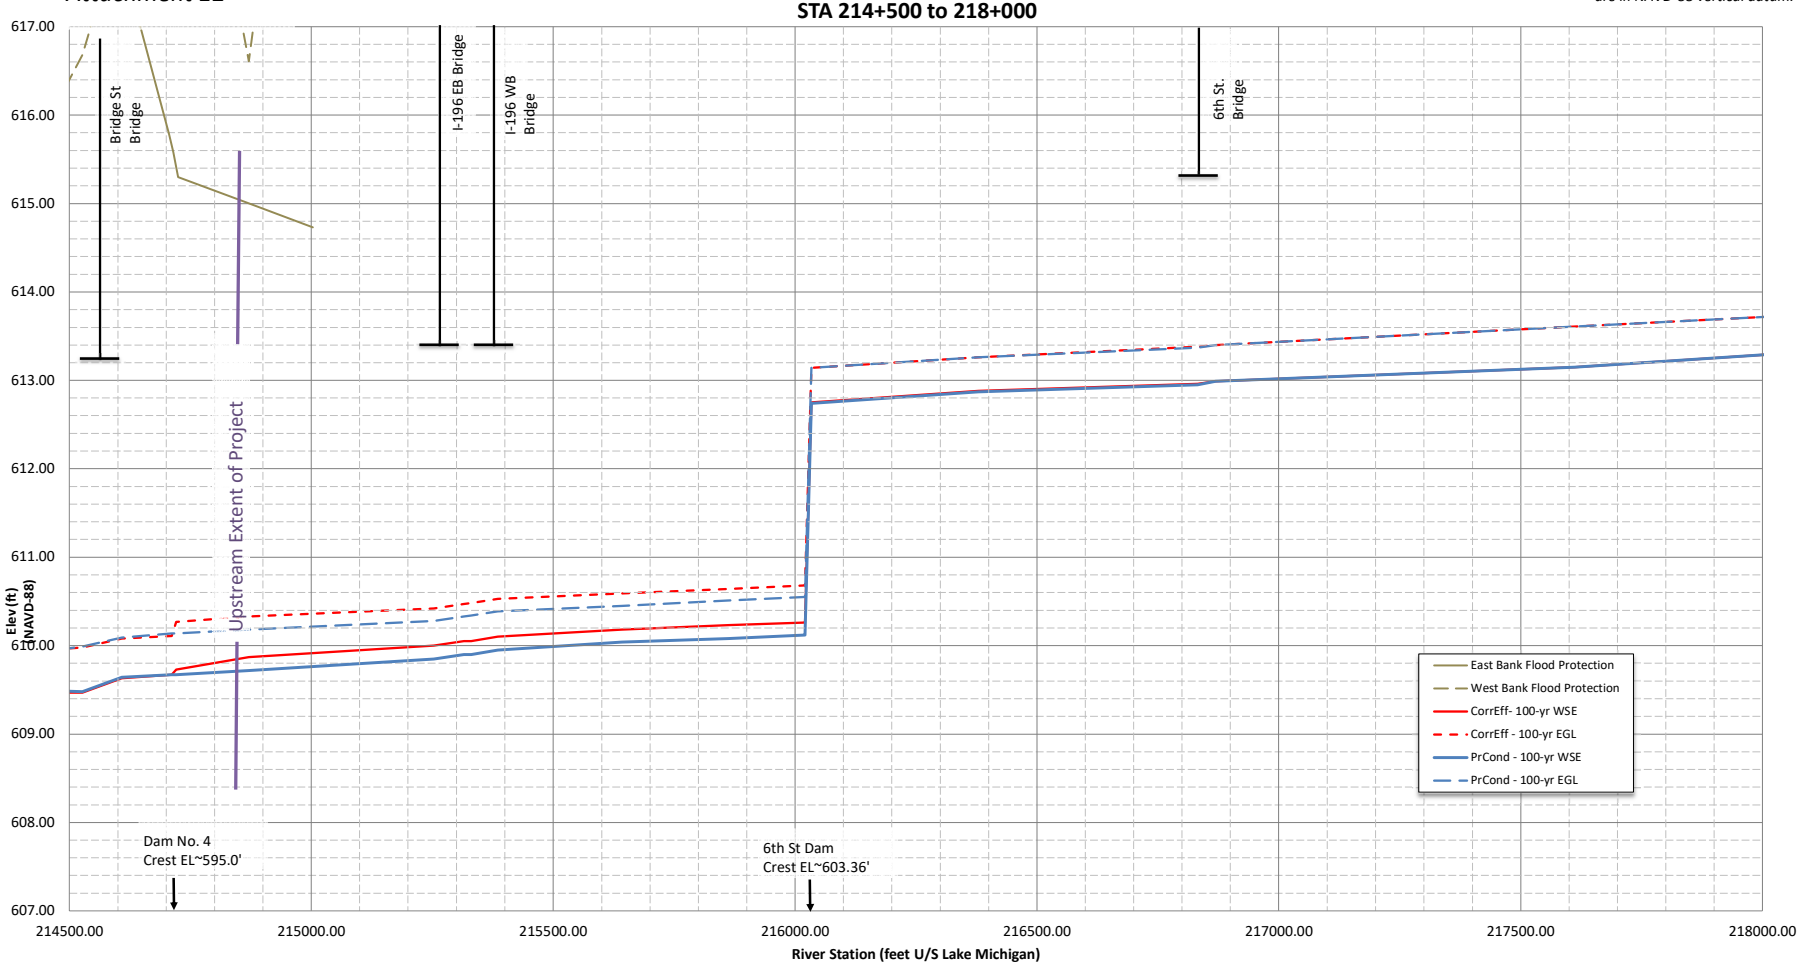
All elevation shown in this chart are in NAVD-88 vertical datum.



Attachment 12

50-yr Flood Modeling Results - Hydraulic and Energy Grade Line
STA 214+500 to 218+000

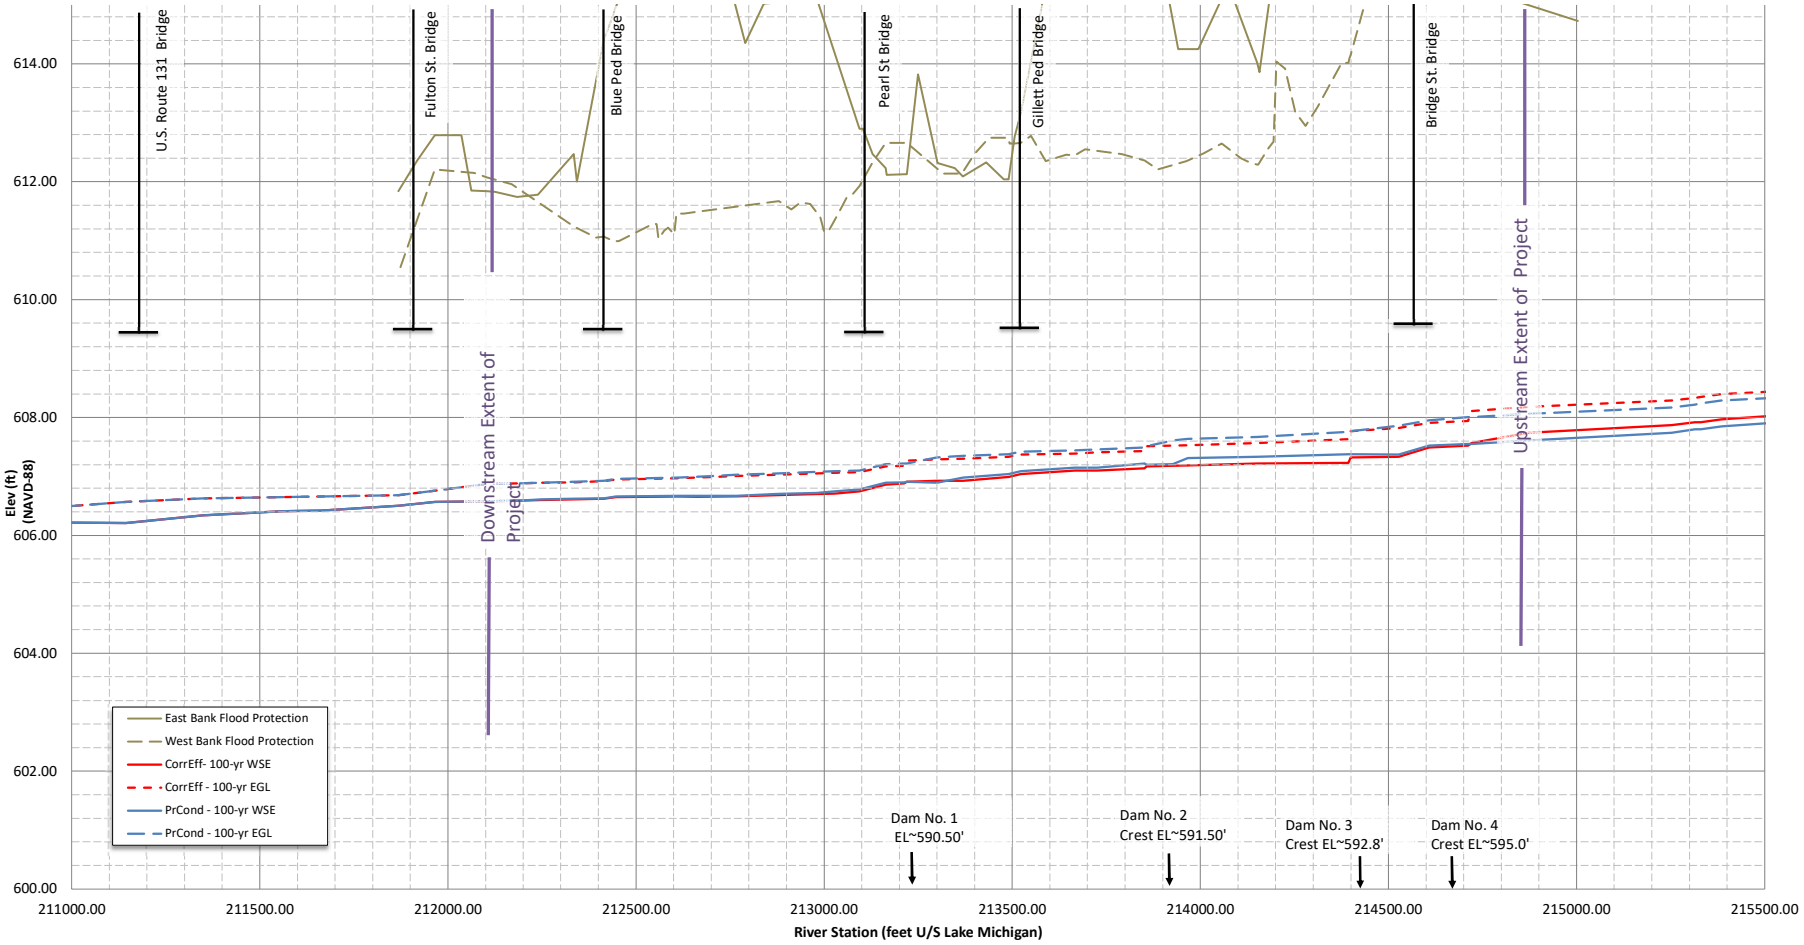
All elevation shown in this chart are in NAVD-88 vertical datum.



Attachment 12

25-yr Flood Modeling Results - Hydraulic and Energy Grade Line
STA 211+000 to 214+500

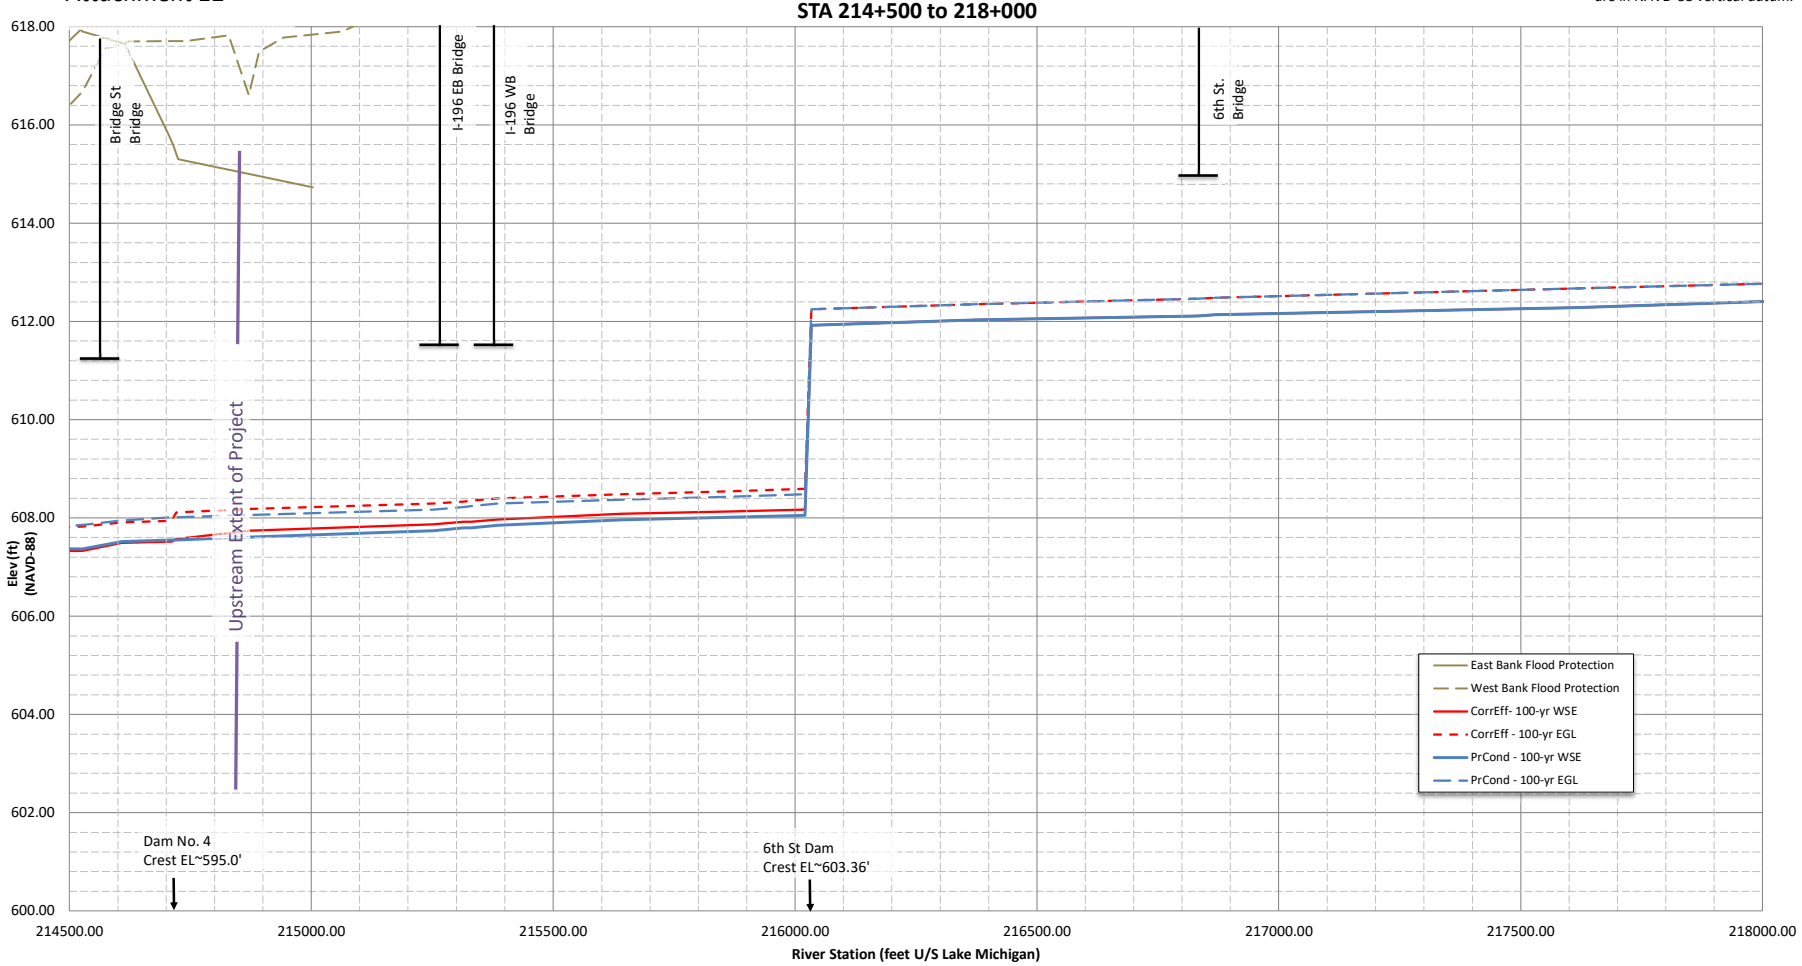
All elevation shown in this chart are in NAVD-88 vertical datum.



Attachment 12

25-yr Flood Modeling Results - Hydraulic and Energy Grade Line
STA 214+500 to 218+000

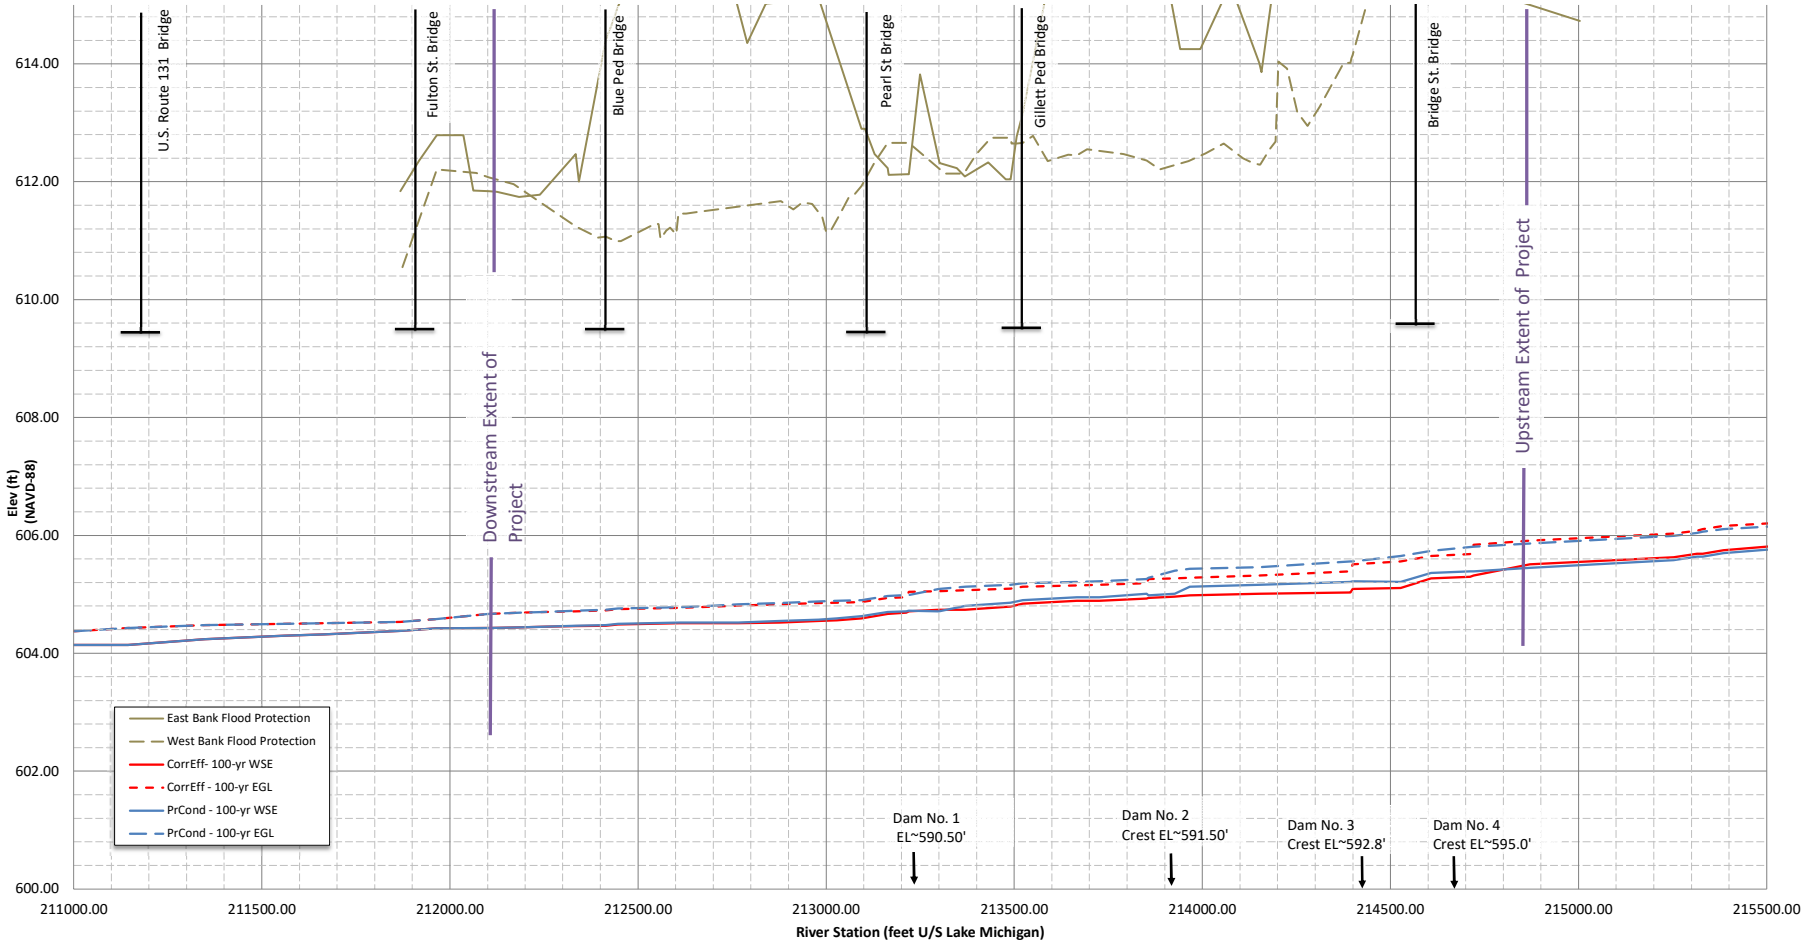
All elevation shown in this chart are in NAVD-88 vertical datum.



Attachment 12

10-yr Flood Modeling Results - Hydraulic and Energy Grade Line
STA 211+000 to 214+500

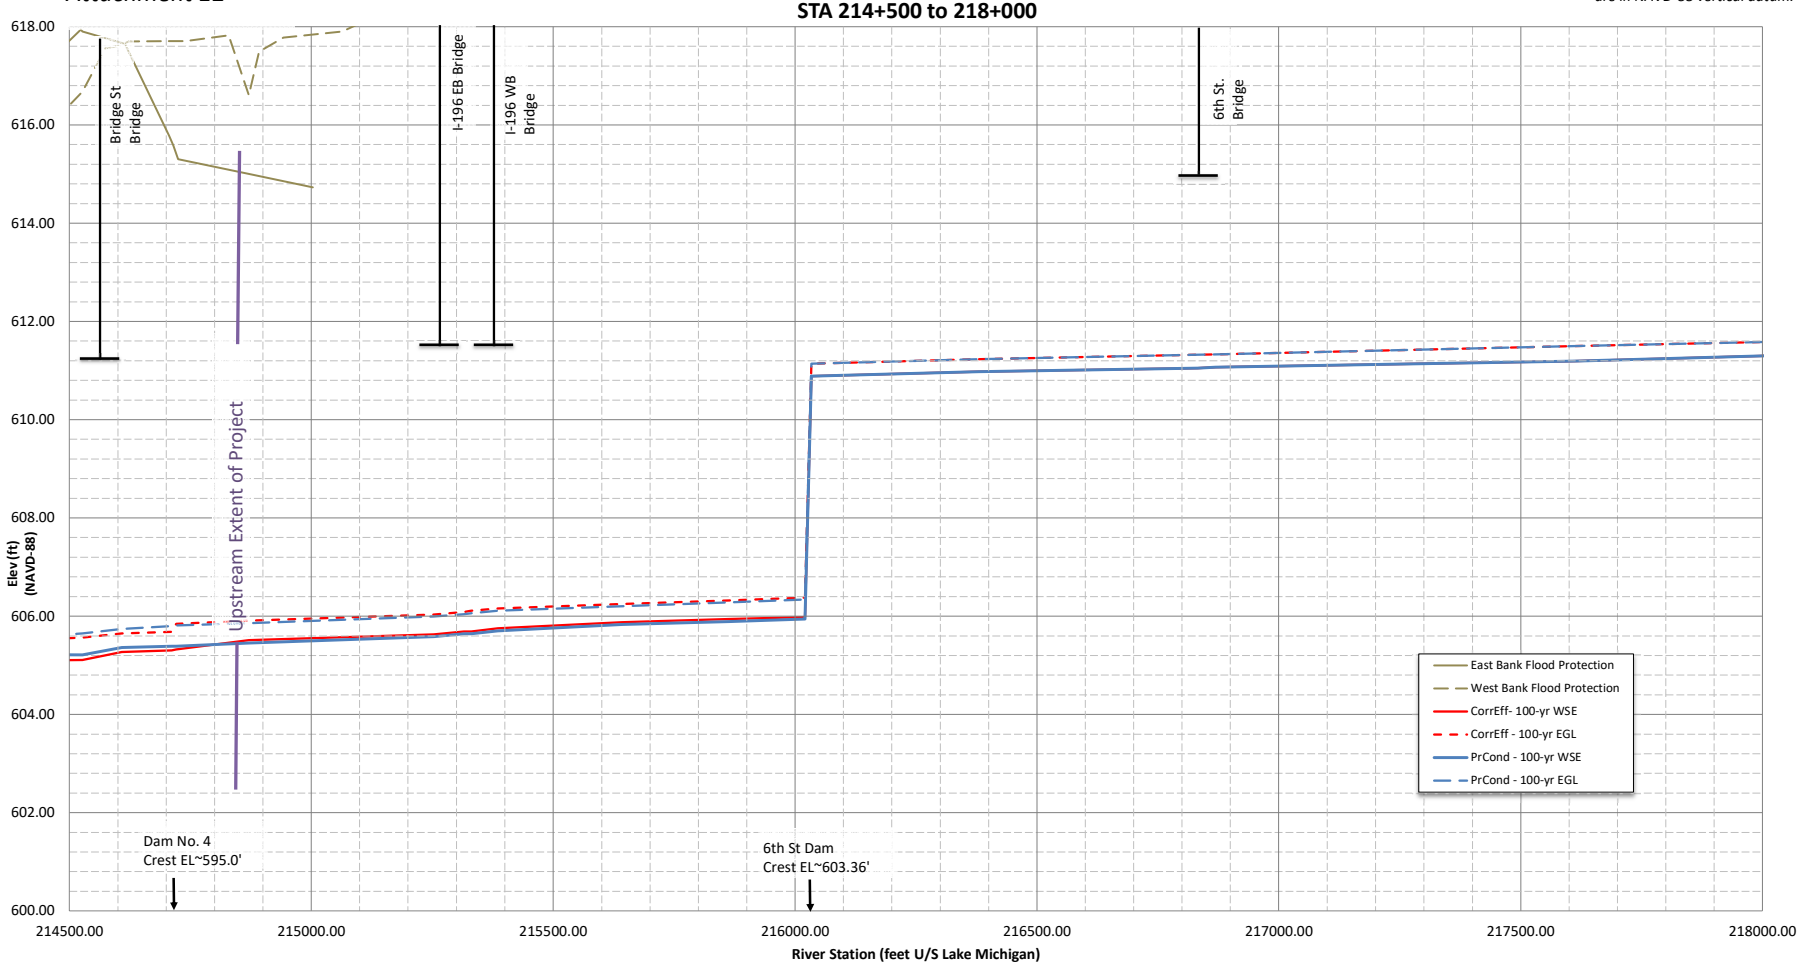
All elevation shown in this chart are in NAVD-88 vertical datum.



Attachment 12

10-yr Flood Modeling Results - Hydraulic and Energy Grade Line
STA 214+500 to 218+000

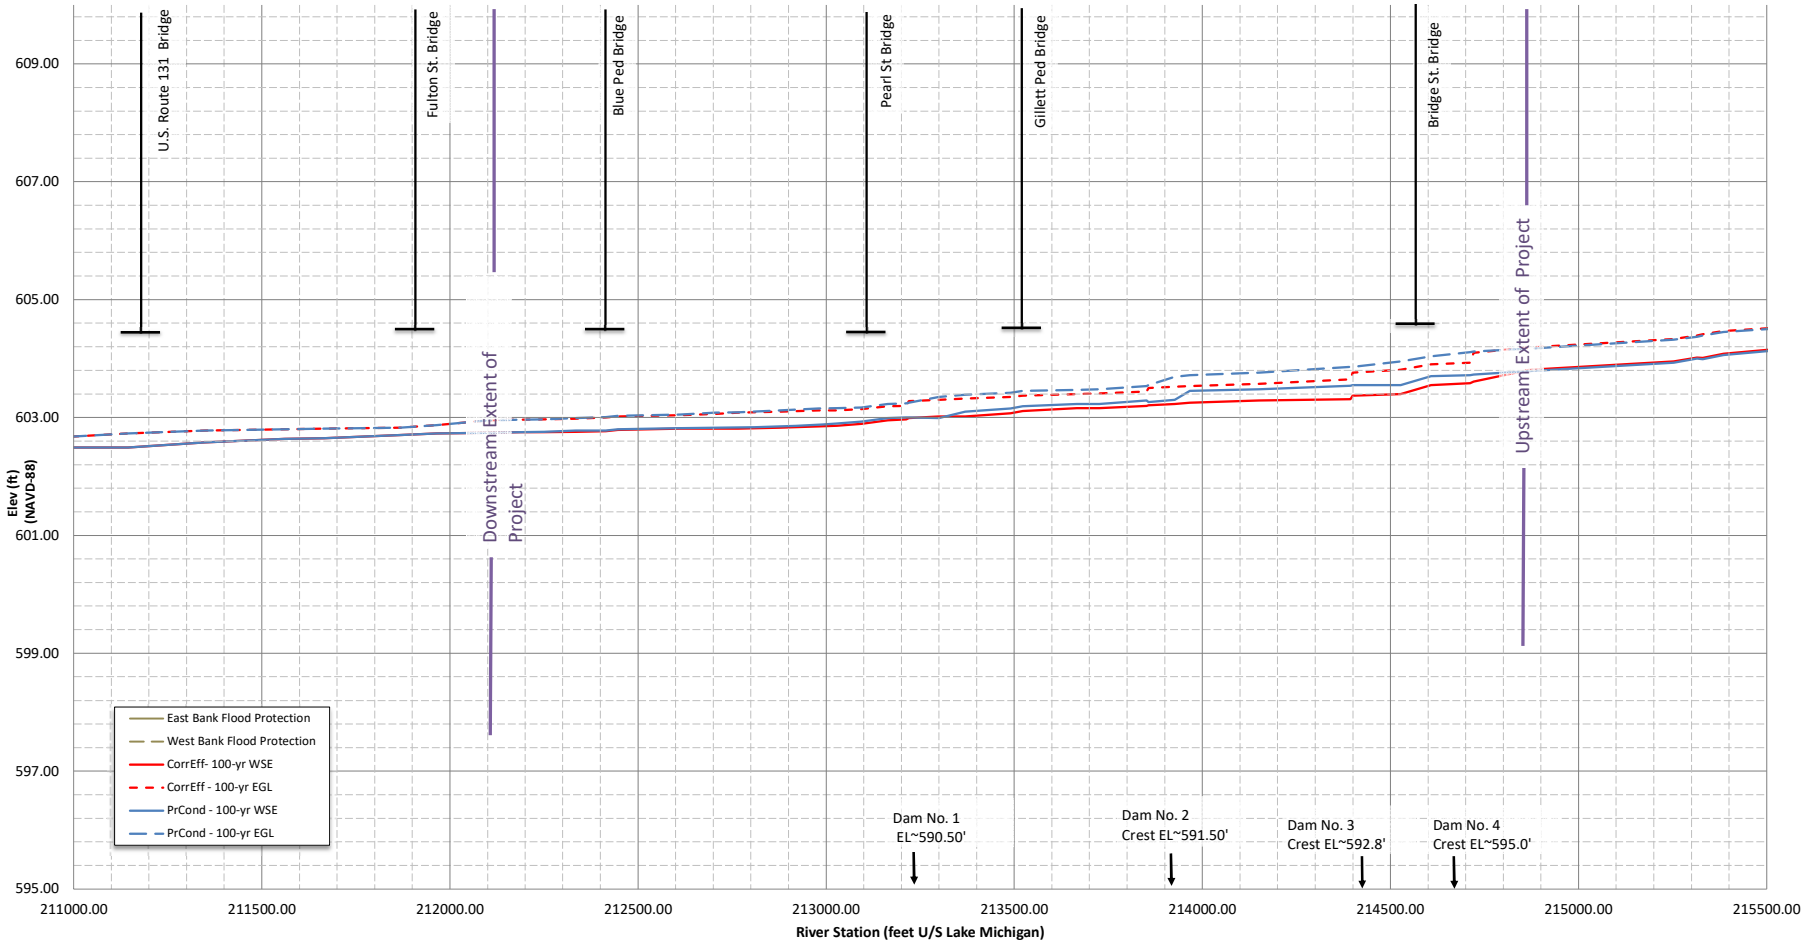
All elevation shown in this chart are in NAVD-88 vertical datum.



Attachment 12

5-yr Flood Modeling Results - Hydraulic and Energy Grade Line
STA 211+000 to 214+500

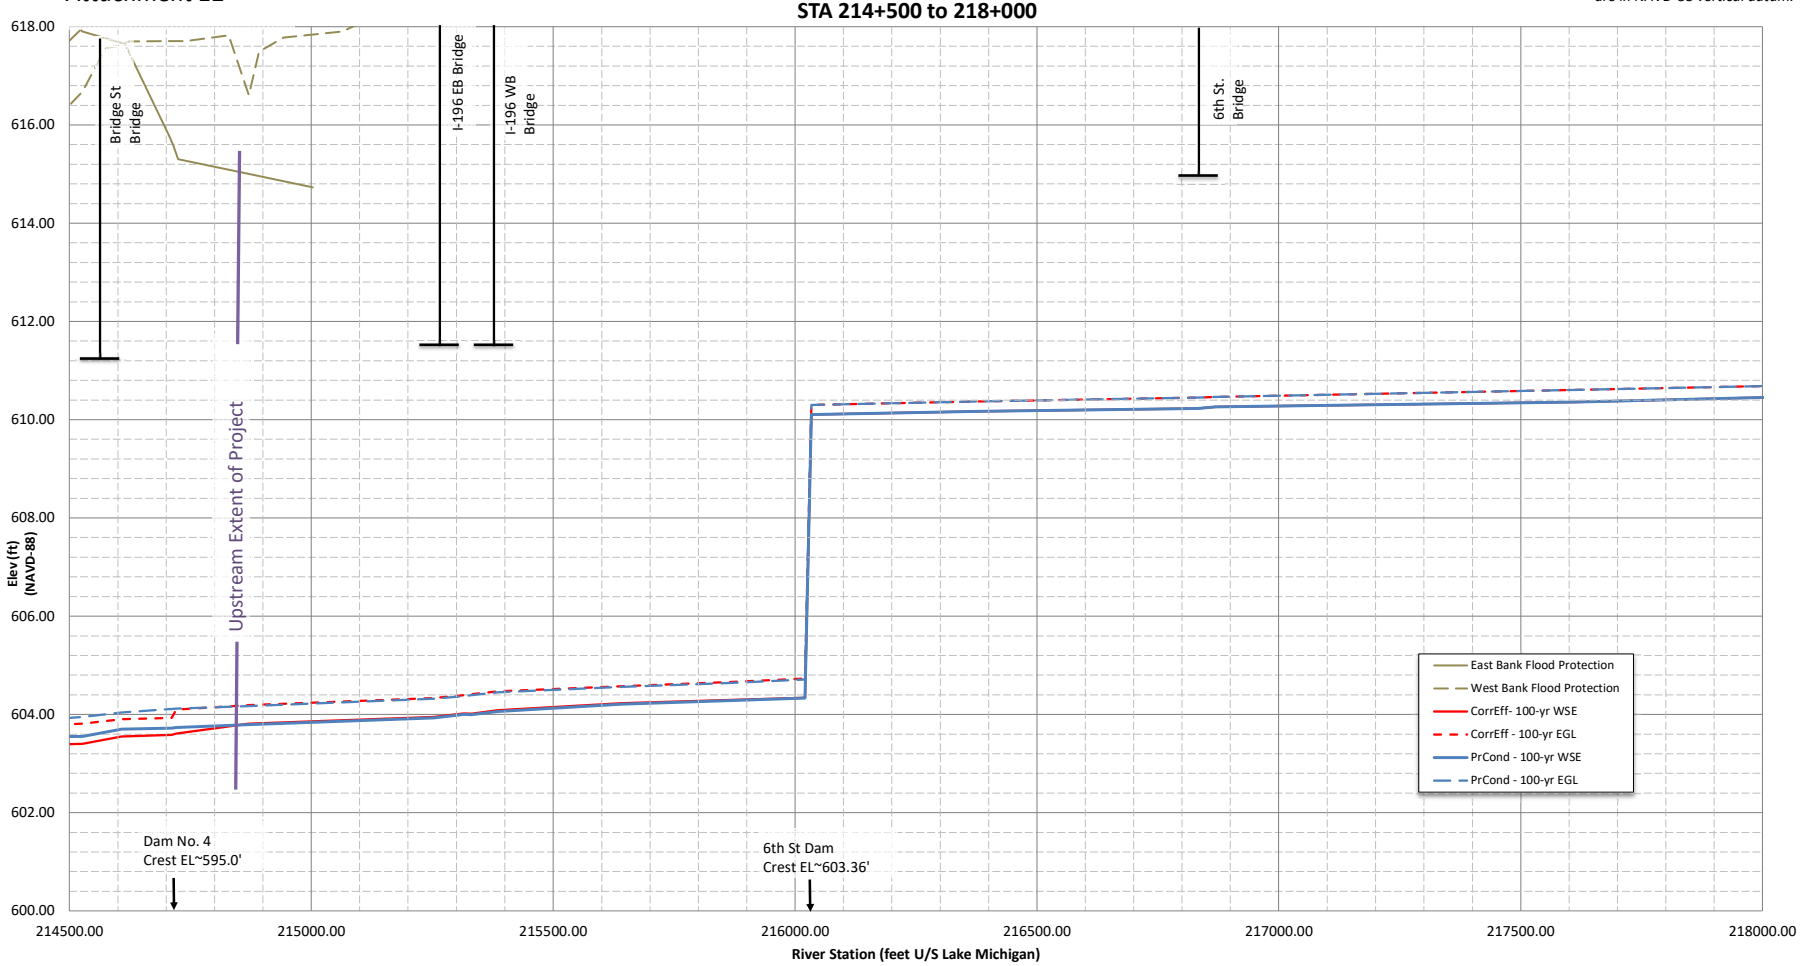
All elevation shown in this chart are in NAVD-88 vertical datum.



Attachment 12

5-yr Flood Modeling Results - Hydraulic and Energy Grade Line
STA 214+500 to 218+000

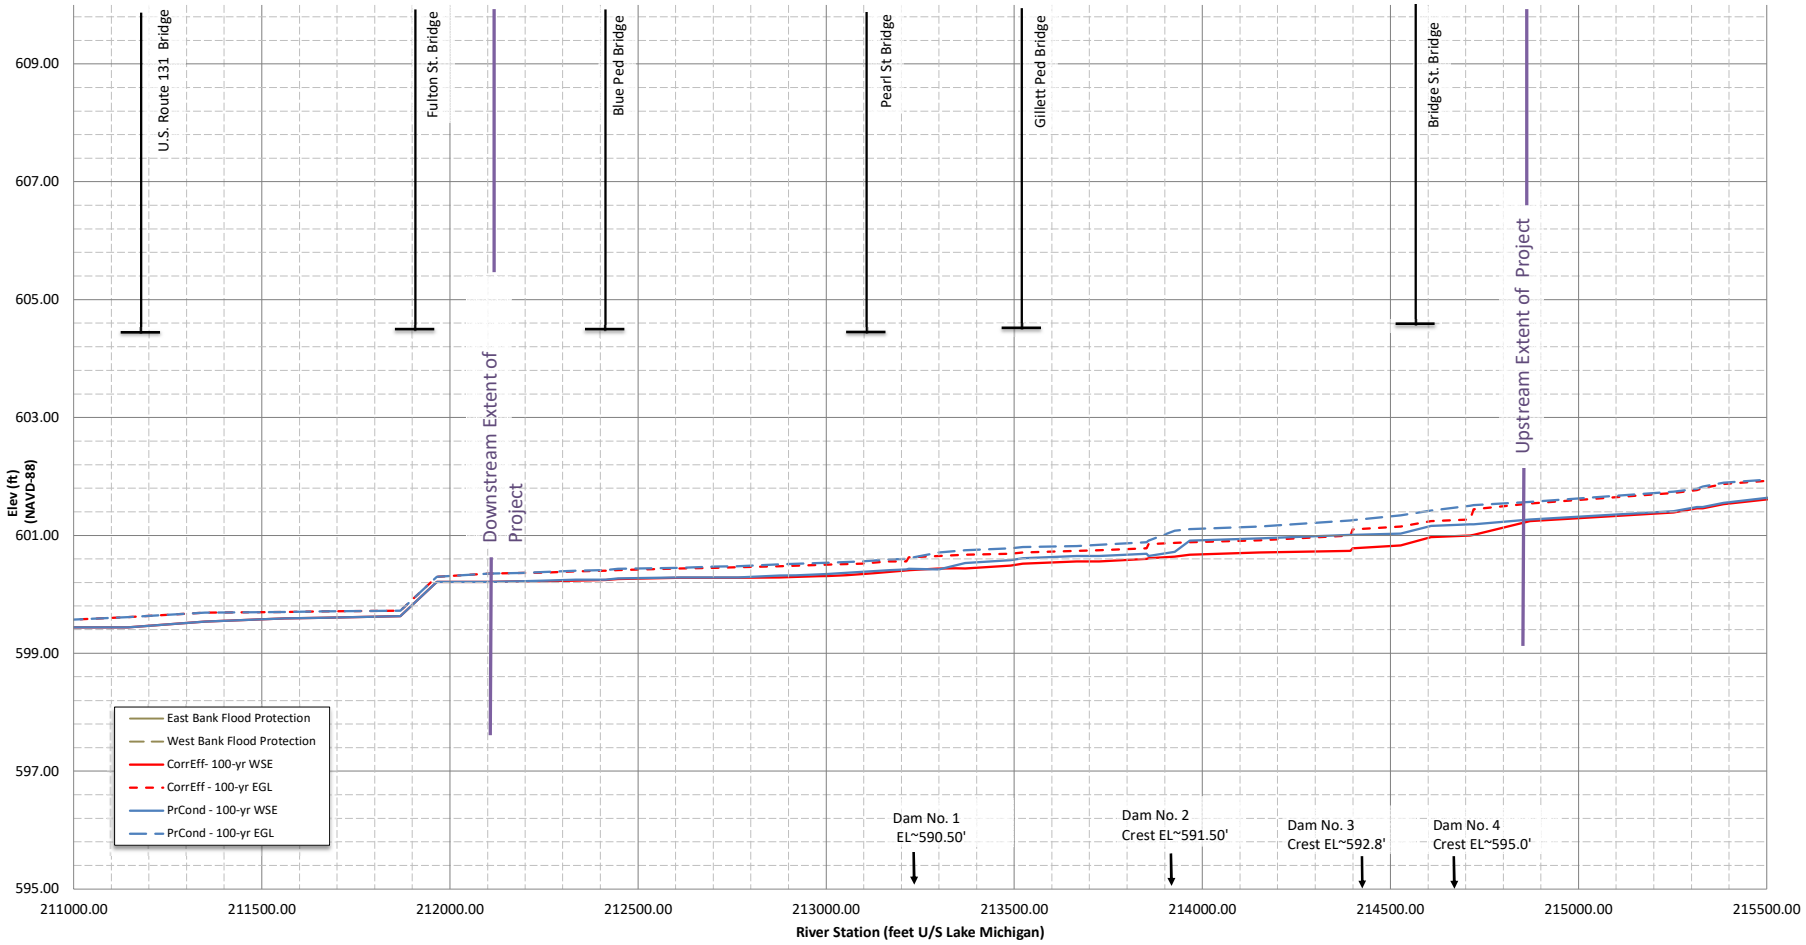
All elevation shown in this chart are in NAVD-88 vertical datum.



Attachment 12

2-yr Flood Modeling Results - Hydraulic and Energy Grade Line
STA 211+000 to 214+500

All elevation shown in this chart are in NAVD-88 vertical datum.



Attachment 12

2-yr Flood Modeling Results - Hydraulic and Energy Grade Line
STA 214+500 to 218+000

All elevation shown in this chart are in NAVD-88 vertical datum.

Temporary Conditions Hydraulics Report
GRAND RIVER REVITALIZATION LOWER REACH PROJECT
GRAND RAPIDS, MICHIGAN

Temporary Conditions Hydraulics Report

Prepared for:
City of Grand Rapids

Prepared by:
RiverRestoration
P.O. Box 248
Carbondale, CO 81623

May 2024

This document entitled – Temporary Hydraulic Conditions for the RCPP Reach, Grand River Revitalization Project, Grand Rapids, Michigan was prepared by RiverRestoration.org, LLC for the account of City of Grand Rapids (Client). The material in it reflects the professional judgement of RiverRestoration in light of the scope, schedule, and other limitations stated in the document and in contract between RiverRestoration and Client.

Section 1 - Introduction

This report, prepared for the City of Grand Rapids, details the harmful interference evaluation of the proposed temporary construction activities within the Lower Reach Project. Harmful interference is defined by Michigan Department of Environmental, Great Lakes and Energy (EGLE) as "causing an increase stage or change in the direction of flow that causes, or is likely to cause: damage to property, a threat to life, pollution, impairment, or destruction of water or other natural resources" (EGLE, 2019).

The models developed herein are for relative comparison of temporary river conditions only. The models developed herein are not intended for the evaluation of National Flood Insurance Program (NFIP) flood hazards under 44 Code of Federal Regulations Part 65.

This hydraulic analysis was conducted to examine potential temporary flood stage impacts resulting from the construction of the Grand River Revitalization Lower Reach Project (Project). The Project spans from the low-head dam upstream of the Bridge Street Bridge to the upstream face of Fulton Street Bridge. A detailed evaluation of flood stage impacts associated with the proposed in-channel improvements of the Project, including background information of the Project can be found in Report I1 - Hydraulics Report.

To construct the Project, temporary causeways, work isolation measures, and other best management practices (BMPs) will encroach into the floodplain of the Grand River through the Project reach. As detailed in this analysis, the proposed temporary conditions required to construct the Project will cause temporary rises in water surface elevations (WSE) for a range of flow rates. These temporary increases in the water surface profile are expected to remain contained within the existing City of Grand Rapids flood protection system up to the 100-year flood event.

Section 2 - Method of Analysis

Corrected effective and temporary construction conditions water surface profiles were computed using HEC-RAS 4.1, provided by the U.S. Army Corps of Engineers. All elevations are given in North American Vertical Datum of 1998 (NAVD88).

The flow rates for Grand River through the Project reach were obtained from EGLE and are provided in Table 1. Correspondence regarding the determination of project flow rates can be found in Attachment 2 of Report I1. This report is meant to be a supplement of the main Hydraulics Report with a focus on temporary construction conditions. All hydraulic modeling assumptions made in the overall hydraulic analysis effort are carried through to this report.

Table 1. *Project Flow Rates*

Recurrence Interval	Flow (cfs)
100-yr	50,000
50-yr	44,000
25-yr	38,000
10-yr	31,000
5-yr	26,000
2-yr	18,000
Bankfull	13,000

2.1 Corrected Effective Model

As described in Report I1, Section 2.2.2, the Corrected Effective Model was developed from the Effective Model and includes 11 additional cross sections to represent the location of the proposed channel improvements. The HEC-RAS output for this model is under plan "Corrected Effective."

2.2 Temporary Conditions Models

The project is proposed to be constructed by access provided from a staging area in Ah-Nab-Awen Park and in-channel causeways accessing each work area from the park. At Dam 2, the west half of the proposed improvements would be constructed within isolation conditions after installing a cofferdam around the work area and diverting flow to the east side of the channel. Construction activities will be limited by flow depths in the river are anticipated to be performed during flow rates less than approximately 4,000 cfs. Above this flow, depths would likely exceed those for safe and efficient construction in the flowing water and would begin to overtop the cofferdam at the Dam 2 location. Additionally, because construction would only occur during the lower flow periods, the temporary structures (causeways and cofferdam) are proposed to remain in the river during periods of higher flows when construction is unable to occur. Removing temporary structures prior to 4,000 cfs being exceeded would not provide for feasible construction of the project.

The proposed hydraulic feature at the Dam 2 location replaces the grade control function of Dam 3 and part of Dam 4. In order to maintain stable grade control within the reach until the completion of the proposed new hydraulic feature, the removal of Dams 3 and 4 is proposed to be done after the completion of the feature at Dam 2. This also allows for the coffered work at Dam 2 to occur during historically low flows during summer (July and August) when construction would be most efficient and potential impacts to flooding or bridge scour during isolation would be minimized.

Refer to the construction sequencing discussion in Report D1 and the temporary care of water sheets (T Sheets) in permit drawings for reference.

Three temporary conditions models have been evaluated for potential flood impacts:

- Temporary Conditions Model 1 assumes that causeways to Dams 1 and 2, as well as causeways to all work downstream of Pearl Street have been installed and all dams remain in place.
- Temporary Conditions Model 2 assumes that the cofferdam at the Dam 2 location has been installed in addition to all causeways as described in model 1. All dams remain in place
- Temporary Conditions Model 3 assumes that the cofferdam has been removed and all proposed improvements have been completed, but all causeways still need to be removed from the channel.

These temporary conditions models make conservative assumptions as to what all would potentially be in the river at one time. This is to provide the contractor flexibility to perform the work as efficiently as possible, while still adhering to the sequencing detailed in Report D1.

The HEC-RAS plans corresponding to the three temporary conditions models are discussed in the following subsections and cross section maps are provided in Attachment 1 to this report. A full description of the recommended construction sequencing and care of water activities can be found in Report D1 – Construction Sequencing and Methods.

Section 3 - Modeling Results and Discussion

The baseline comparison of the 100-year WSE between Effective Model and the Corrected Effective Model is presented in Figure 1 of TOC No. 5 Hydraulics Report. In order to evaluate the potential rises to the flood profile during construction, water surface elevations for the temporary conditions were compared to water surface elevations for corrected effective conditions for the range of flow rates listed in Section 2. Conservative assumptions have been made for each temporary conditions model; all assume that all causeways are in the river at the same time, and temporary conditions models 2 and 3 assume all proposed improvements are in the river along with temporary causeways before they are removed. Table 2 (following page) presents the 100-year WSE comparisons. Complete tabular results of water surface elevations for the 100-yr flood event are provided in Attachment 2.

The modeling results show that for the 100-year event, the temporary conditions are predicted to cause maximum increases in water levels downstream of 6th Street Dam of 0.07 feet for temporary conditions model 1, 0.10 feet for temporary conditions model 2, and 0.11 feet for temporary conditions model 3.

Temporary conditions models 1 and 2 calculate small increases in modeled 100-yr water surfaces upstream of 6th Street Dam. These conditions have been conservatively modeled in regard to potential temporary fill in the river at one time, and would be very unlikely to exist in the river over winter and into spring when historically large flow events occur. Temporary conditions model 1 represents construction during the ~3-week duration of coffered isolation at Dam 2. This condition would be during the historically driest part of the year (July and August) and would not be left in the river over winter. Temporary conditions model 2 represents the stage of construction, immediately following the completion of the Dam 2 feature, but immediately before the removal of dams 3 and 4, which would be a very short period

of time (~1 - 2 weeks). This condition would only be left over winter if Dams 3 and 4 are unable to be safely removed prior to flow conditions being too deep or swift in the fall.

The anticipated construction schedule is to have all improvements (including dam removals) completed in one season. All potential increases in flood levels associated with construction would be a temporary condition due to the presence of work isolation measures and construction activities and would remain within the City's flood protection system.

3.1. Conclusion

Modeling results indicate that with conservative assumptions, the temporary conditions may result small modeled increases of 0.01'-0.11' in 100-year water levels within the project area downstream of 6th Street Dam during construction and could have a very low probability of small modeled increases of up to 0.03' upstream of 6th Street Dam under the temporary conditions when Dams 3 and 4 are in place with temporary fill in the project reach. Modeled increases would remain with the City's flood protection system. Under the anticipated construction schedule, there would be no modeled increase in 100-yr levels upstream of 6th Street Dam during winter and spring months when large flooding has historically occurred most frequently. Any increases modeled for this evaluation of temporary construction activities associated with the project are less significant than those modeled and permitted for the recent in-river work on the I-196 Bridge piers.

It is the opinion of the engineer, Scott Prins (RiverRestoration.org, LLC), that based on the temporary hydraulic modeling results and analysis presented here, the temporary condition of the Project will cause no harmful interference to upstream properties.

1.0 INTRODUCTION

The concrete 6th Street Dam in the Grand River at Grand Rapids, MI has been assumed to be an effective barrier to upstream migration of the invasive sea lamprey (*Petromyzon marinus*) (Great Lakes Fishery Commission (GLFC), 2018). Proposed modifications to the Grand River associated with the Grand River Revitalization Lower Reach Project include the demolition of four low-head dams and construction of naturalized instream restoration features between Bridge Street and Fulton Street. Hydraulic conditions at the 6th Street Dam under post-project conditions have been modeled to show that the hydraulics of 6th Street Dam will not be impacted to result in reduced effectiveness in blocking sea lamprey as compared to corrected effective conditions. Temporary conditions during construction have also been modeled to evaluate impacts to tailwater conditions at 6th Street Dam. These evaluations and corresponding hydraulic modeling results are reported in this memorandum.

Hydraulic comparisons are made to channel conditions prior to recent instream work conducted by Michigan Department of Transportation (MDOT). This is referred to as the Existing Conditions Configuration herein.

2.0 MODELING RESULTS EVALUATION OF EXISTING AND PROPOSED CONDITIONS

Flow rates below bankfull flow of 13,000 cfs, were evaluated in SRH-2D and comparisons were made between existing and proposed conditions. Flood flows, greater than bankfull flow, were evaluated and compared using the effective HEC-RAS FEMA flood model.

Tailwater elevations were taken from both models directly downstream of 6th Street Dam, at River Station 2160+20.2; Table 1 compares the calculated rating curves. The crest of 6th Street Dam is submerged by tailwater at the 5-year flood (26,000 cfs). Proposed Conditions tailwater elevations were modeled to remain at or at or below Existing Conditions, within modeling error, for all flow rates evaluated. An 18" vertical separation between tailwater and crest was maintained for similar flow rates as existing conditions.

Table 1: Comparison of modeled tailwater elevations at 6th Street Dam

3.0 MODELING RESULTS EVALUATION OF EXISTING AND TEMPORARY CONSTRUCTION CONDITIONS

The project is proposed to be constructed by access provided from a staging area in Ah-Nab-Awen Park and in-channel causeways accessing each work area from the park. At Dam 2, the west half of the proposed improvements would be constructed within isolation conditions after installing a cofferdam around the work area and diverting flow to the east side of the channel. Construction activities will be limited by flow depths in the river are anticipated to be performed during flow rates less than approximately 4,000 cfs. Above this flow, depths would likely exceed those for safe and efficient construction in the flowing water and would begin to overtop the cofferdam at the Dam 2 location. Additionally, because construction would only occur during the lower flow periods, the temporary structures (causeways and cofferdam) are proposed to remain in the river during periods of higher flows when construction is unable to occur. Removing temporary structures prior to 4,000 cfs being exceeded would not provide for feasible construction of the project.

The proposed hydraulic feature at the Dam 2 location replaces the grade control function of Dam 3 and part of Dam 4. In order to maintain stable grade control within the reach until the completion of the proposed new hydraulic feature, the removal of Dams 3 and 4 is proposed to be done after the completion of the feature at Dam 2.

Refer to the construction sequencing discussion in Report D1 and the temporary care of water sheets (T Sheets) in permit drawings for reference.

Three temporary conditions models have been evaluated for potential impacts to tailwater at 6th Street Dam:

- Temporary Conditions Model 1 assumes that causeways to Dams 1 and 2, as well as causeways to all work downstream of Pearl Street have bene installed and all dams remain in place.
- Temporary Conditions Model 2 assumes that the cofferdam at the Dam 2 location has been installed in addition to all causeways as described in model 1. All dams remain in place
- Temporary Conditions Model 3 assumes that the cofferdam has been removed and all proposed improvements have been completed, but all causeways still need to be removed from the channel.

These temporary conditions models make conservative assumptions as to what all would potentially be in the river at one time. This is to provide the contractor flexibility to perform the work as efficiently as possible, while still adhering to the sequencing detailed in Report D1.

Modeling results for tailwater at 6th Street Dam are compared and discussed for each temporary condition below. Low flows, which include flow rates below bankfull flow of 13,000 cfs, were evaluated in SRH-2D and comparisons were made between existing and temporary conditions. High flows, which includes flow rates greater than bankfull flow, were evaluated and compared using the effective HEC-RAS FEMA flood model. Tailwater elevations were taken from both models directly downstream of 6th Street Dam, at River Station 2160+20.2.

3.1 Temporary Conditions Model 1

Table 1 compares the calculated rating curves for Existing Conditions and Temporary Conditions; the crest of 6th Street Dam is submerged by tailwater at the 5-year flood (26,000 cfs). Modeling results indicate potential for increased tailwater elevations of up to 0.37 feet and an 18" vertical separation from tailwater to dam crest being maintained for flow rates below 18,000 cfs.

Table 2: Comparison of modeled tailwater elevations at 6th Street Dam for Temporary Conditions Model 1

Flowrate (cfs)	Existing Conditions (ft)	Temporary Conditions (ft)	Modeled Change in Tailwater (ft)	Modeling Results
1,200	595.92	596.25	0.33	SRH-2D
2,500	596.64	596.96	0.32	
3,900	597.26	597.58	0.32

4.0 WATER TEMPERATURE

Water temperature plays a major role in predicting when sea lampreys may be migrating upriver. The following information is included to corelate flow rates and water temperature to various times of year. The project will not have an impact on these correlations. Sea lampreys typically spawn in the Grand River in the late winter through spring months (February through June) (USFWS, *personal communication*). Table 5 provides the calculated mean-monthly flow rates and corresponding average temperatures. For the flow data. forty-years of discharge data were obtained from USGS Gage 04119000 and a mean-monthly flow rate was calculated from the mean-daily rate. For water temperatures, 10°C has been identified as a target, with migration beginning as temperatures sustain above 10°C. The annual hydrograph is summarized along with water temperature in Figure 1.

Table 5: Mean monthly flow rates for active spawning months

Month -	Mean daily flow ft^3/s	Mean monthly water temp. ^oC
February	4,878	2
March	7,725	4
April	7,387	10
May	5,696	15
June	4,024	21

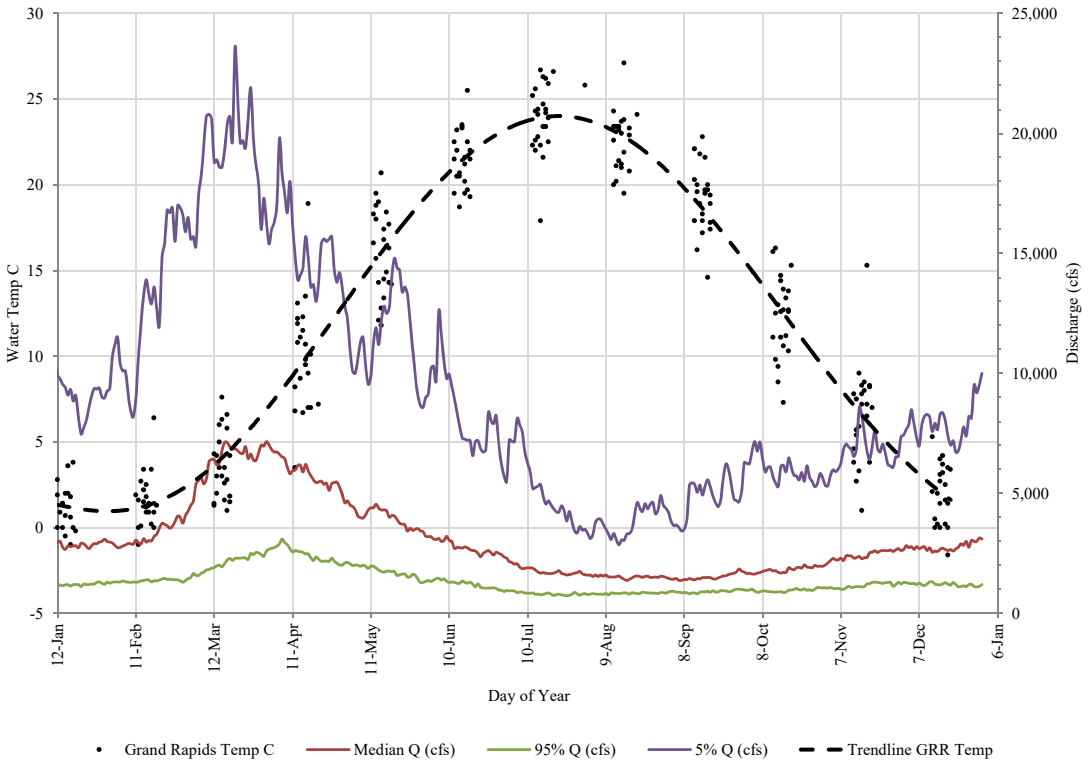

Figure 1: Annual hydrograph with water temperature

5.0 CONCLUSION

The systemic processes of the river and hydraulic characteristics of the 6th Street Dam that contribute to blockage of sea lampreys is not explicitly understood and blockage is likely a combination of various components, including water temperature, vertical free over-fall from crest to tailwater, as well as velocity of flow over and through the dam.

The hydraulic function of 6th Street Dam as a barrier to sea lampreys is not anticipated to be negatively affected by the Lower Reach project. The systemic processes of the river and hydraulic characteristics of the dam that contribute to blockage of sea lampreys is not explicitly understood and blockage is likely a combination of various components, including water temperature, vertical free over-fall from tailwater to crest, as well as velocity of flow over and through the dam.

The project would have no effect on water temperatures or on the dam structure itself.

Modeling results indicate that tailwater elevations would remain at or below existing conditions, within modeling error. Based on this evaluation, the function of 6th Street Dam as a barrier to sea lampreys is anticipated to remain as effective as the existing condition.

The removal of Dams 3 and 4 would be sequenced after the completion of the proposed feature at Dam 2 as means to maintain stable grade control within the reach through construction. The addition of obstruction associated with the temporary causeways and cofferdam resulted in small, modeled increases in tailwater at 6th Street Dam. For this reason, installation of temporary structures would begin immediately following sea lamprey migration season (July 1st) if flow conditions allow. If flows are low enough before sea lamprey migration season ends, isolation measures would be installed if approved after coordination with the USFWS Sea Lamprey Control Program.

Construction is anticipated to be potentially completed in one season but will be dependent on flow conditions throughout the season. If conditions do not allow for full completion of work in one season, some temporary causeway material may be left in the channel over winter (along with all constructed proposed improvements). Potential increases in modeled tailwater elevations that may result if this is the case have been minimized by prioritizing the removal of Dams 3 and 4 immediately following the completion of the feature at Dam 2. Potential modeled impacts to tailwater over winter are represented by temporary conditions models 2 and 3; condition 2 assumes Dams 3 and 4 remain in place and condition 3 assumes they've been removed, which would be the more likely scenario given the anticipated construction schedule.

Section 1 – Introduction

Sediment transport was evaluated for existing and proposed conditions of the Grand River Revitalization Lower Reach Project. Sediment analyses are important to predict long-term stability and function while seeking project benefits and evaluating maintenance requirements. The Grand River at Grand Rapids, MI is a unique geomorphic channel, with a locally steep-gradient and a glacially deposited remnant encompassed within an otherwise low-gradient, sand-bed channel. As the flowrate in the river increases above baseline summer flows, the backwater from the downstream reach affects progressively more upstream area of the steep-gradient channel, reducing sediment transport potential. As such, the sediment dynamics are complex and are a function of both the discharge of the river as well as the location within the project reach. This report describes the sediment analyses performed including survey sampling procedures as well as capacity and competency calculations and presents implications for long-term stability. Proposed instream alterations are not anticipated to have significant effects on the sediment dynamics extending beyond the project reach.

The project reach is composed of a stable substrate with transporting sediment loads, supplied from upstream, passing over the substrate. Transient deposition of upstream sediment load may occur within the reach.

1.1 Sediment Sampling

Sediment sampling has been performed both quantitatively and qualitatively beginning in 2011. Sampling was performed upstream and downstream of the project reach, as well as within the project reach. Analysis of the samples indicates that the channel bed upstream of Ann Street and downstream of US-131 are primarily composed of uniform sand. A broken bedrock outcrop with glacio-fluvial alluvium deposits exists between Ann St. and I-196. Glacio-fluvial alluvium deposits make up the substrate within the project reach between I-196 and Fulton Street. Sampling results indicate that sand supplied from the upstream reach is transported through the project reach to downstream areas. Data also allude to the transport of coarser materials from the upstream end of the project reach which deposit out of the total mobile load at the slope break near Fulton Street.

In 2013, sediment grab samples were collected by RiverRestoration at three locations upstream and downstream of the project site as displayed in Figure 1 to compare with sampling within the project reach in order to evaluate transport of the upstream supply through the reach. Grab samples were obtained near Riverside Park, at Fulton Street Bridge, and downstream of the project reach past the US-131 Bridge. The collected samples were analyzed using sieve distributions by MTC in 2015. Figure 2 illustrates particle size distributions determined by MTC (MTC, 2015) with primarily fine to medium sand indicated upstream and downstream of the project reach (represented in Figure 2 by circles and squares, d_{50} = 0.39 mm) and coarse sand to fine gravel near the downstream extent of the project site (represented by triangles, d_{50} = 3.71 mm). Distributions of the bed sample sizes are provided in Table 1.

Table 1. Grand River Bed Sample Size Distributions (mm)

Location	*D85*	*D60*	*D50*	*D30*	*D15*	*D10*	*Cc*	*Cu*
Riverside Park	0.53	0.42	0.39	0.33	0.29	0.27	0.96	1.57
Fulton St	8.91	4.82	3.71	1.43	0.27	0.23	1.86	21.14

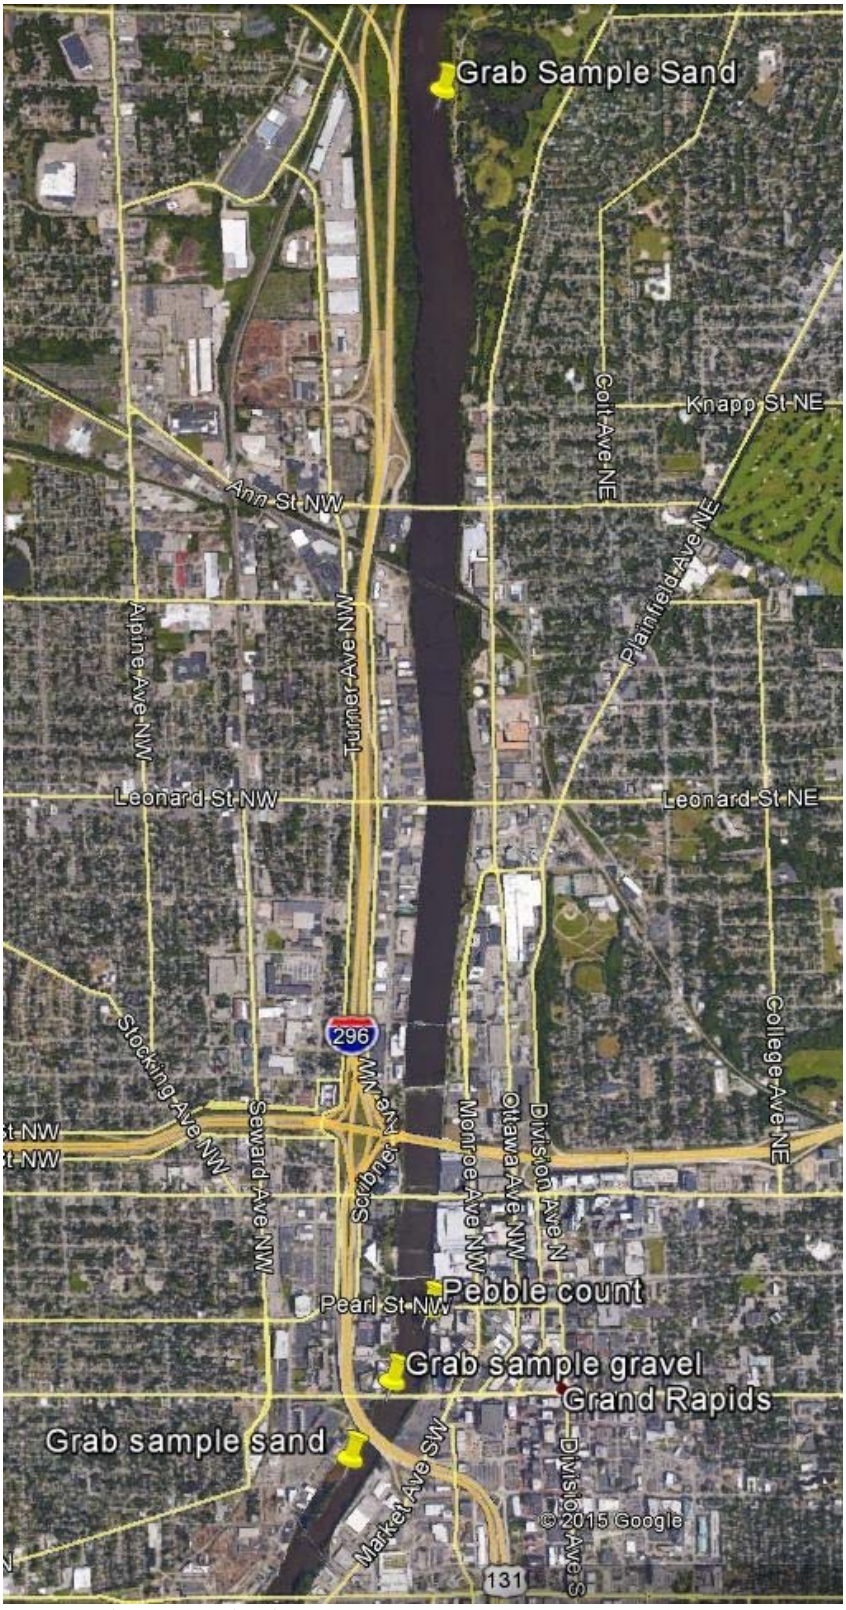

Figure 1. Sediment sampling locations

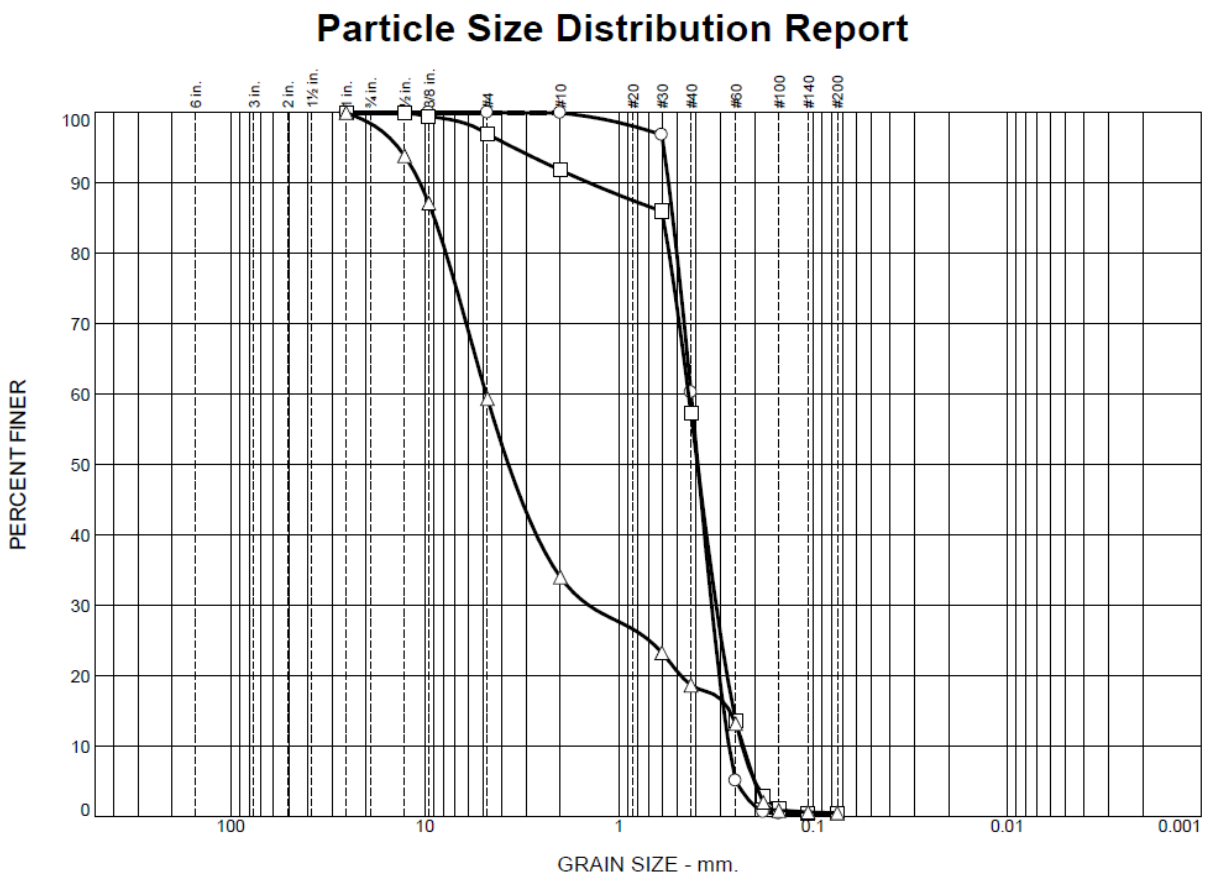

Figure 2. Sediment sampling locations; circle – Riverside Park, square – downstream of project reach, triangle – Fulton St. (MTC, 2015).

1.1.1 Sampling Within the Project Reach

Sampling efforts to date include:

- RiverRestoration performed bathymetric survey in Fall of 2011 combined with probing to develop qualitative substrate characterization;
- Wolman pebble counts of bed substrate were collected August 4, 2015 downstream of Pearl St and June 17, 2016 upstream of Gillette Bridge in sites selected as qualitatively mobile gravel deposits;
- Mussel surveys were performed by EcoAnalysts Inc. (ESI) in November 2014; during the mussel survey, bed substrates were also qualitatively described and mapped (ESI, 2014); and
- A comprehensive substrate sampling of the riverbed was performed by MTC in March 2017. The MTC 2017 sampling included two sample locations between each set of bridges from 6th Street Dam to Fulton Street for a total of 12 substrate samples. Probe sampling was conducted to determine the amount of substrate larger than 6 inches (coarse cobble). Ponar grab sampling was then performed at each location to determine the gradation of the substrate finer than 6 inches (MTC, 2017). The locations and percentages of coarse material (greater than 6 inches) for each sampling location are presented in Table 2. The locations of the samples are presented in Figure 3. On average, 60% of the sampled riverbed was determined to be coarser than 6 inches. Throughout the project reach, the percent distribution of sand ranged from 0% to 5% of the recovered substrate. The downstream sampling location, immediately upstream of Fulton

Street, produced larger percentages of sand; this is indicative of the change in the energy grade of the river at this location.

- Additional substrate sampling was performed in July 2020 at 11 locations using a combination of Geoprobe and Pitch Sampler equipment to collect 1.75-inch diameter macrocores followed by both grain size analysis and chemical analysis of collected samples. The sampling locations for the 2020 survey are presented in Figure 3. During both the 2020 sampling and the 2017, shallow refusal with respect to the planned sampling depths and poor sampler recovery were encountered due to the frequent presence of coarse gravel, cobble and boulder. The 2020 sampling results indicated the presence of coarse-grained material with less than 5% of the material passing the 200 sieve. Each sample was tested for heavy metals, volatile organic compounds, semi-volatile organic compounds, pesticides, polychlorinated biphenyls, dioxins and furan, per and polyfluoroalkyl substances, biochemical oxygen demand, and total solids. Refer to the sampling report for more information (MTC. 2020)

Table 2: MTC, 2017 Sampling Data

Sample Location	Location (MI State Plane South)		Water Depth (ft)	River Bottom Consistency Based on Probing (%)		d50 of collected sample (inches)	Estimated d50 of sample area (inches)
	Northing	Easting		< 6-inches	> 6-inches

Section 2 – Inflowing Suspended Sediment Load Data

The inflowing suspended sediment load was determined based on gage data in order to evaluate the potential for long-term aggradation or degradation. Five USGS stream gages on the Grand River were referenced for comparing sampled sediment loads. Data from these gage records were analyzed along with the sediment modeling findings from Baird (2007). The locations of the USGS gages are presented in Figure 4. A summary of the USGS gages referenced is provided in Table 3.

Table 3. Grand River Gaged Sediment Data

USGS Gage	Proximity to Grand Rapids	Period of Record	Suspended Sediment Concentration, mg/L			Suspended Sediment Discharge, tons/day		
			Max.	Min.	Avg.	Max.	Min.	Avg.
04113000 Lansing	90 miles U/S	4/20/1975 - 5/29/1975	312	24	136	9,440	9,440	9,440
04114000 Portland	65 miles U/S	4/20/1975 - 4/23/1975	347	96	208	11,400	11,400	11,400

04119300 Eastmanville	22 miles D/S	2/14/1979 - 10/7/1994	294	1	33.7	8,930	5	669.6
04119400 Eastmanville	25 miles D/S	4/29/2011 - 10/15/2014	895	4	37.9	44,900	29	1,570

2.1 Calibrated SWAT Model (Baird 2007)

Baird (2007) compiled available data on transporting sediment loads and concentrations in the Grand River watershed and used the results to calibrate a comprehensive Soil and Water Assessment Tool (SWAT) model. SWAT uses a wide range of input parameters to predict long-term responses to changes in land use, climate, and vegetation in the form of sediment yields and water quality. The input parameters represent climate, hydrology, ponds and wetlands, groundwater, main channel draining, soils, land cover, and land use. The sediment load of the Lower Grand River (Downstream of Lansing) was predicted by the SWAT model and compared to sampled data at all USGS gage stations shown in Figure 3, with the exception of #04119400, which was not available at the time of the report. All the input parameters listed above are specific to the Grand River watershed. The hydrology, which seasonally fluctuates, has the largest effect on the sediment load. By comparing sediment load to discharge at various points along the river, predictions can be made about suspended sediment load based on a given discharge. The comparison of the SWAT model and gage data are presented in Figure 5. Sediment load in mg/L is presented on the *y*-axis and related to the discharge in cubic meters per second (cms) of the river on the *x*-axis. Both axes are on logarithmic scales.

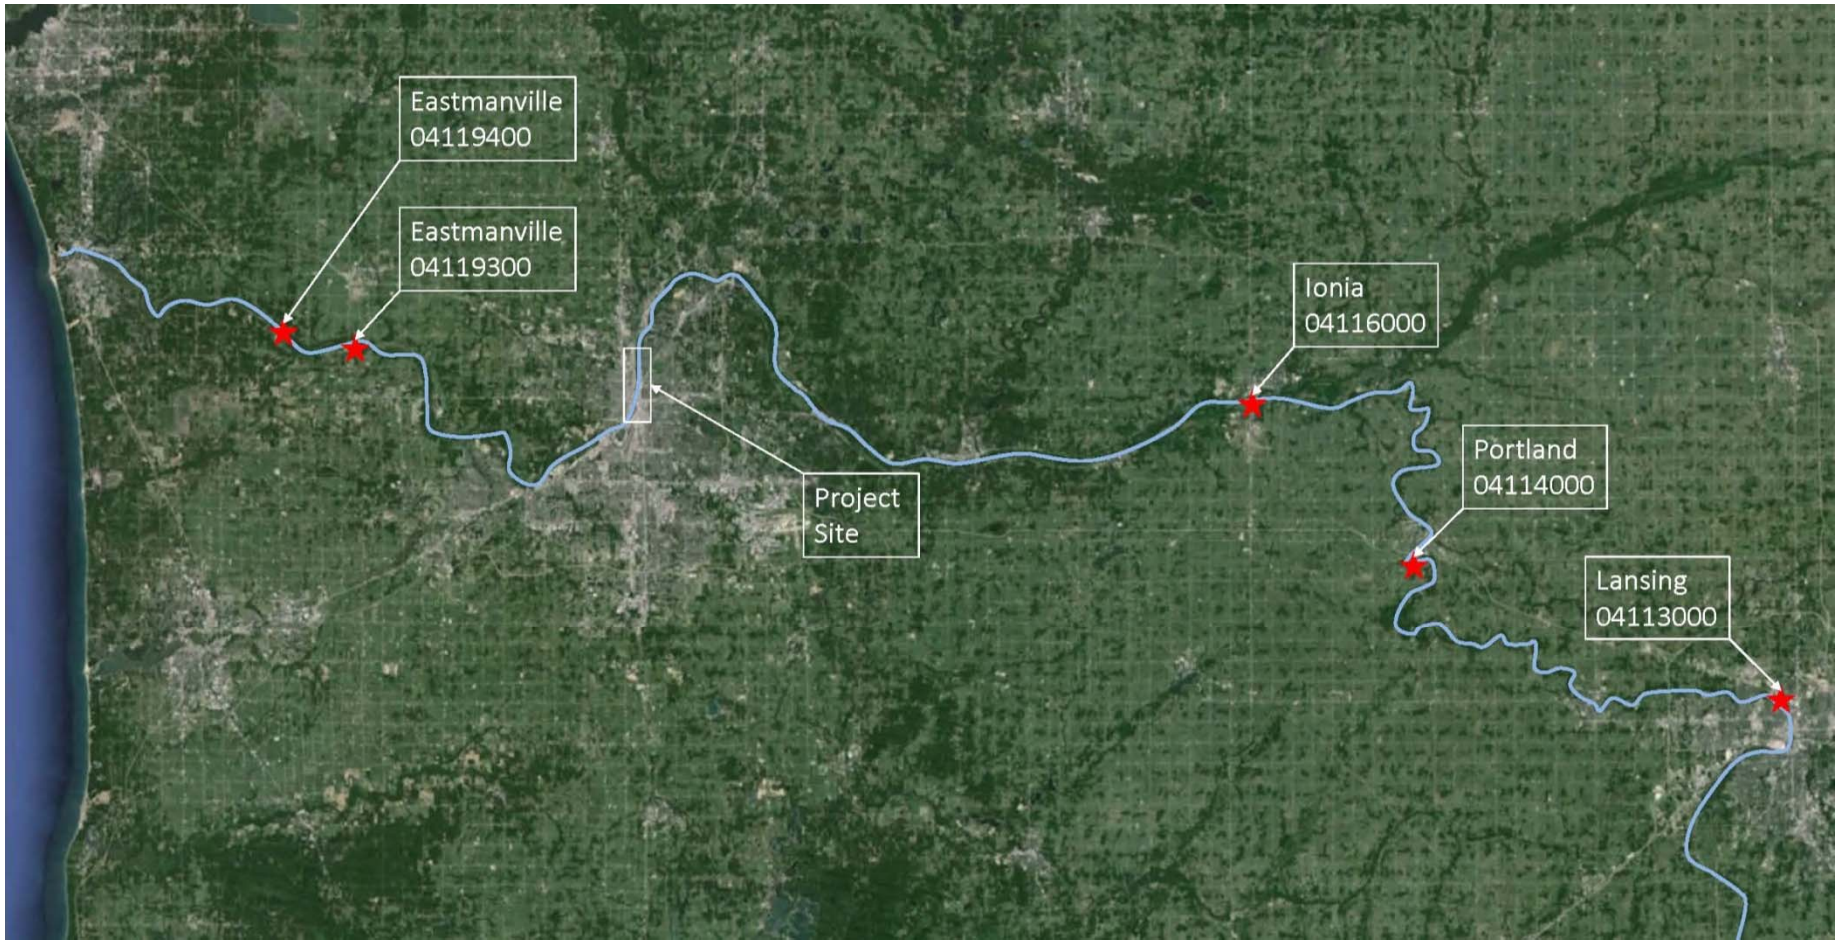

Figure 4. USGS Gage Locations

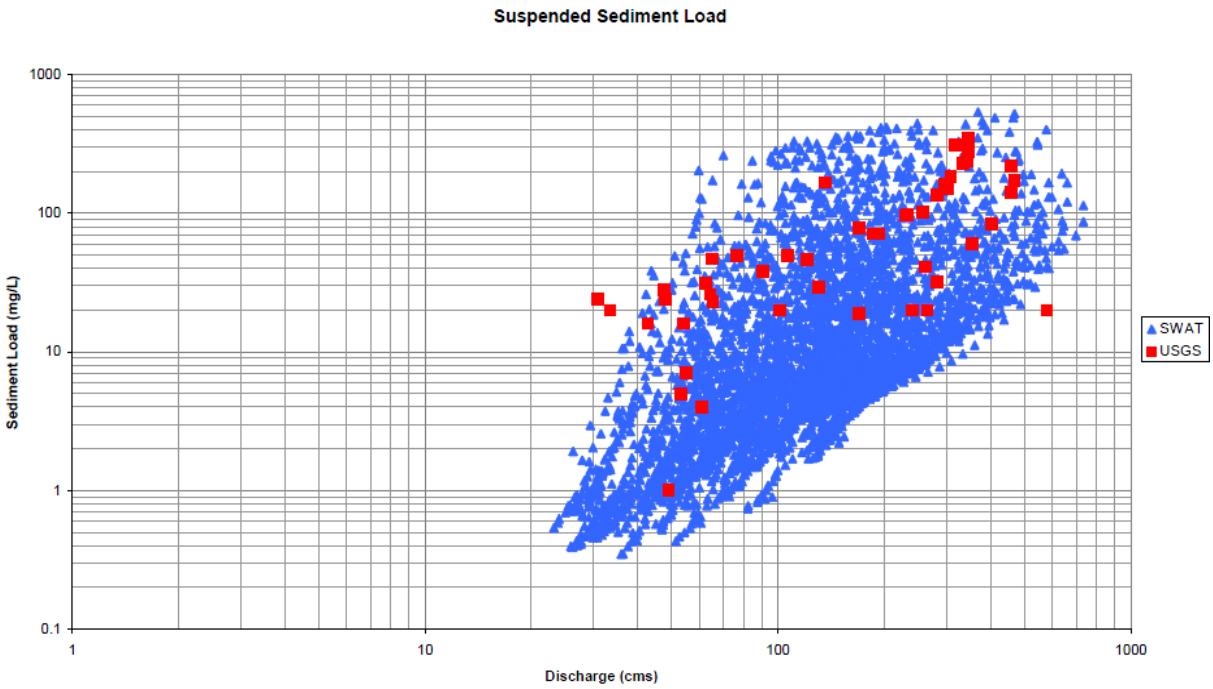

Figure 5. Sediment Load Comparison between USGS Data and SWAT Simulation (from Baird, 2007)

The suspended sediment load data from Baird (2007) was obtained from the four USGS gages presented in Figure 4, excluding #04119400. Figure 6 presents this same data with the addition of new data from gage #04119400 which contains data from 2011 to 2014. It should be noted that the units for discharge in Figure 6 are cubic feet per second (cfs) and not cms.

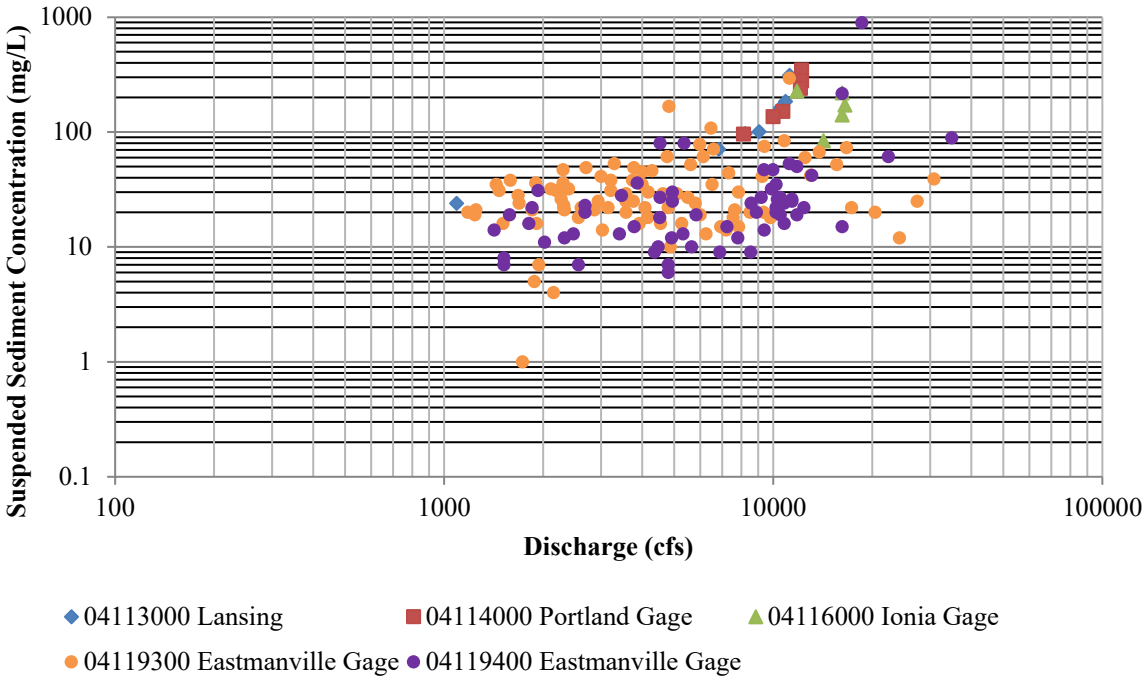

Figure 6. Suspended Sediment Concentration from USGS Gages near Grand Rapids, MI

2.2 *Verification of stable channel dimensions of inflowing reach using Copeland's Method*

Data presented in the above figures provided a range of inflowing sediment concentrations that were evaluated in HEC-RAS using the Copeland method to examine and verify stable channel dimensions for the existing inflowing reach. The Copeland method in HEC-RAS is empirically derived and uses sediment discharge relationships developed by Brownlie (1981) to compare channel width and depth to bed slope in order to predict aggradation or degradation of the channel based on an assumed inflowing sediment load.

The channel characteristics of the upstream reach were evaluated first. This evaluation was based on the dimensions of the river adjacent to Riverside Park near river station 2295+00. Channel dimensions and hydraulic parameters for the upstream reach include a median channel width of 600 feet, 1:1 side slopes on the banks, manning's roughness of 0.03, a particle gradation based on bed sampling of a d_{84} of course sand (0.53 mm), a d_{50} of medium sand (0.39 mm), and a d_{16} of fine sand (0.29 mm), an effective discharge of 10,000 ft^3/s, and an inflowing sediment concentration ranging from 10 mg/L to 300 mg/L which was based on the gaged sediment concentrations. The range of inflowing sediment concentrations produced a range of stable bed slopes at a channel width of 600 feet. Figure 7 presents the predicted stable bed slopes for a channel width of 600 feet over the range of inflowing sediment concentrations. Degradation of the assumed particle size distribution is predicted for conditions above the line and aggradation for conditions below the line.

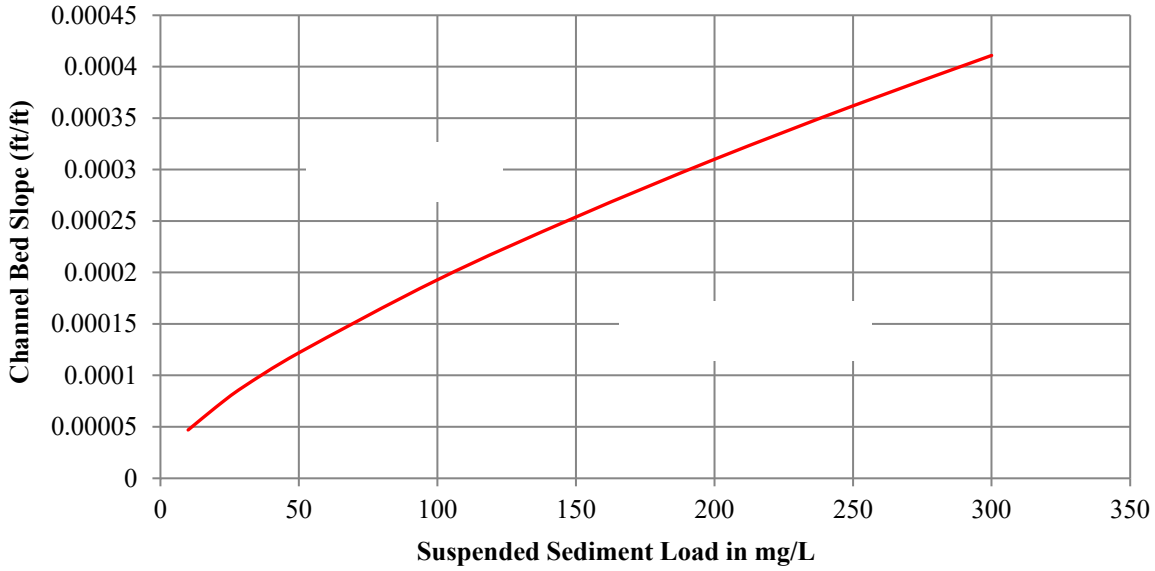

Figure 7: Copeland Stability Curve for 600 ft Wide Channel and Inflowing Sediment Load of 10 mg/L and 300 mg/L

According to gage data, the majority of the inflowing sediment load data were between 10 and 100 mg/L. The stable bed slopes predicted for this sediment concentration range are consistent with slopes calculated from bathymetric survey data. The upstream reach of the Grand River adjacent to Riverside Park is considered a stable reach (i.e. not actively aggrading or degrading) based on calculations, which corresponds to field observations and recent historic reports of the reach. Incoming sediment loads to Riverside Park pass downstream to the project reach; the

anticipated inflowing suspended sediment load to the project reach is 10 to 100 mg/L with the possible larger event of 300 mg/L.

The hydraulic gradient of the Grand River within the project reach is currently distributed by the existing low-head dams with relatively flat water between them. The proposed project seeks to distribute this gradient with more naturally functioning bedforms, including constructed riffles. The imported substrate has been sized to remain stable and also function as hydraulic controls to protect the un-impacted native substrate from being degraded over time. By spreading out the hydraulic gradient over more of the reach, the project would increase the relative energy grade slope between Bridge Street and Fulton Street. The supplied bed load must pass through a much lower-gradient reach upstream. Therefore, there is no concern of aggradation from the inflowing suspended sediment load within the project reach. Instead., inflowing suspended sediment loads are anticipated to seasonally pass through the proposed conditions project reach. The project does not propose importing fine sediment and is not anticipated to have an impact on the suspended sediment load being transported to the lower reach. The potential for local transient deposition of the mobile bed load around in-channel features is discussed in section 5 of this report.

Section 3 – Substrate Mobility Analysis

Sizing of the imported substrate is critical for project success; too small of substrate may mobilize beyond the project reach or destabilize structures through scour, while too large of material may create poor habitat conditions or safety hazards to river users. Balancing these two criteria is the goal of sizing imported substrate.

Therefore, a substrate mobility analysis was performed in order to determine the particle size gradation to use in the proposed stable substrate materials imported to the channel which would avoid persistent degradation of bed material. This analysis compared calculated maximum bed shear stresses to critical shear stresses, or the shear stress at which substrate sizes begin to mobilize.

3.1. Critical Shear Stress and Incipient Motion

Boundary shear-stress magnitudes have been linked to incipient motion of individual particles through empirical and theoretical examination (Julien, 2002). There is a critical shear-stress magnitude (τ_C) which corresponds with the mobilization of a given size class of substrate. Table 4 summarizes mobilization values from Julien (2002). Factors not considered in the values of Table 4 include hydraulic impingement angle, bed slope, substrate matrix, gradation variability, material density, and water temperature.

Shear-stress values from the numerical models can be directly compared to the critical mobility values to approximate the substrate size classification that may remain stable under maximum loading at each location in the Grand River. An incipient motion analysis was performed based on the critical shear stress to determine what individual size particle would be mobile for given flowrates. Bed shear stresses over the proposed grading were iteratively evaluated using hydraulic modeling to determine the critical grain size, or threshold mobile grain size. A factor of safety of 2.0 was then applied to the threshold mobile grain size to determine the proposed gradation of the imported material.

Table 4:Critical Shear Stress by Particle-size Classification for determining approximate condition for sediment mobility - taken from USGS Scientific Investigations Report 2008-5093 (adapted from Julien, 2002)

Particle Classification Name	Ranges of Particle Diameters mm	Shields Parameter (dimensionless)	Critical Bed Shear Stress (τ_C) N/m^2	Critical Bed Shear Stress (τ_C) lb/ft^2
Coarse cobble	128 – 256	0.054 – 0.054	112 – 223	2.34 - 4.66
Fine cobble	64 – 128	0.052 – 0.054	53.8 – 112	1.12 - 2.34
Very coarse gravel	32 – 64	0.05 – 0.052	25.9 – 53.8	0.54 - 1.12
Coarse gravel	16 – 32	0.047 – 0.05	12.2 – 25.9	0.25 - 0.54
Medium gravel	8 – 16	0.044 – 0.047	5.7 – 12.2	0.12 - 0.25
Fine gravel	4 – 8	0.042 – 0.044	2.7 – 5.7	0.056 - 0.12
Very fine gravel	2 – 4	0.039 – 0.042	1.3 – 2.7	0.027 - 0.056
Very coarse sand	1 – 2	0.029 – 0.039	0.47 – 1.3	0.0098 - 0.027
Coarse sand	0.5 – 1	0.033 – 0.029	0.27 – 0.47	0.0056 - 0.0098
Medium sand	0.25 – 0.5	0.048 – 0.033	0.194 – 0.27	0.0041 - 0.0056
Fine sand	0.125 – 0.25	0.072 – 0.048	0.145 – 0.194	0.0030 - 0.0041
Very fine sand	0.0625 – 0.125	0.109 – 0.072	0.110 – 0.145	0.0023 - 0.0030
Coarse silt	0.0310 – 0.0625	0.165 – 0.109	0.0826 – 0.110	0.0017 - 0.0023
Medium silt	0.0156 – 0.0310	0.25 – 0.165	0.0630 – 0.0826	0.0013 - 0.0017
Fine silt	0.0078 – 0.0156	0.3 – 0.25	0.0378 – 0.0630	0.00079 - 0.0013

Hydraulic modeling was performed with SRH-2D, a publicly available computer program from the US Bureau of Reclamation which has been extensively validated for the open-channel flow applications similar to the Grand River (Lai, 2010). The model uses an implicit numerical scheme to calculate the depth-averaged (i.e. two-dimensional) Navier-Stokes equations and generates flow depths, velocities, turbulence parameters, and boundary shear stresses. The unstructured mesh used in the numerical model was sufficiently refined (approximately 1-ft^2 cells) to capture hydraulic gradients produced by the modeled surface.

The determining hydraulic parameter for substrate stability is boundary shear stress. SRH-2D calculates boundary shear stress vectors as follows:

$$(\tau_{bx}, \tau_{by}) = \frac{\rho g n^2 \sqrt{U^2 + V^2}(U, V)}{h^{1/3}}$$

where:
τ_{bx} = bed shear stress in the *x*-direction;
τ_{bx} = bed shear stress in the *y*-direction;
ρ = water density;
g = gravitational acceleration;
n = Manning roughness coefficient;
U = mean-flow velocity in the *x*-direction;
V = mean-flow velocity in the *y*-direction; and
h = flow depth.

Bed shear stresses calculated by SRH-2D are dependent on Manning roughness values, which have been specified based on substrate size. Therefore, sizing the imported substrate to have a minimum factor of safety of 2.0 was an iterative process of calculating maximum bed shear, changing the gradation of substate and increasing Manning n values, and re-calculating bed shear stresses.

3.2. Imported Substrate Gradations

By applying a factor of safety to imported d_{50} grain sizes, the substrate used in the proposed grading has been designed to avoid degradation while promoting a more natural river function. At larger flood flows, backwater from downstream of the project reach reduces bed shear stresses and corresponding mobile particle sizes. For this reason, calculated bed shear stresses for flowrates ranging from 890 ft^3/s to 31,000 ft^3/s were evaluated in SRH-2D. Shear stress values calculated in HEC-RAS during larger flood events were also referenced in this evaluation. The maximum bed shear values over the full range of flows were used to evaluate against existing conditions as well as in reference to Table 4 to determine the gradations and locations of proposed stable substrate fill material. Maximum bed shear maps are presented in Figure 9.

The final substrate configuration of the channel will be a combination of both imported materials and existing native alluvium. Over native alluvium, the existing substrate was found to remain stable with a minimum factor of safety of 2.0 under post-project hydraulics. Where proposed conditions create shear stress exceeding the existing material stability, stable material will be imported to the channel. Figure 8 illustrates the proposed finished grade substrate configuration after construction. Imported substrates for the proposed grading include:

1) Fine alluvium for proposed shear stresses exceeding 1.1 lb/ft^2, specified with d_{50} of 3 inches;
2) Coarse alluvium and riprap for shear stresses exceeding 5.6 lb/ft^2, specified with d_{50} of 12 inches; and
3) Boulder at the structure crests and where shear stresses exceed 18.7 lb/ft^2.

Riprap will be used as sub-grade control structures within riffle features; plain and heavy riprap per MDOT will be combined to provide a d_{50} of 12 inches. The recommended gradations for the imported alluvium size classes are presented in Table 5.

Table 5. Recommended imported coarse and fine alluvium gradations

Weight	Indicator	Coarse	Fine
100%	Passing	30”	8”
60%-85%	Passing	20”	6”
35%-65%	Passing	12”	3”
25%-55%	Passing	8”	1.5”
15%-35%	Passing	4”	3/4”
0%-5%	Passing	1.5”	1/2”
	D_{85}	18”	6”
	D_{50}	12”	3”
	D_{30}	4”	3/4”

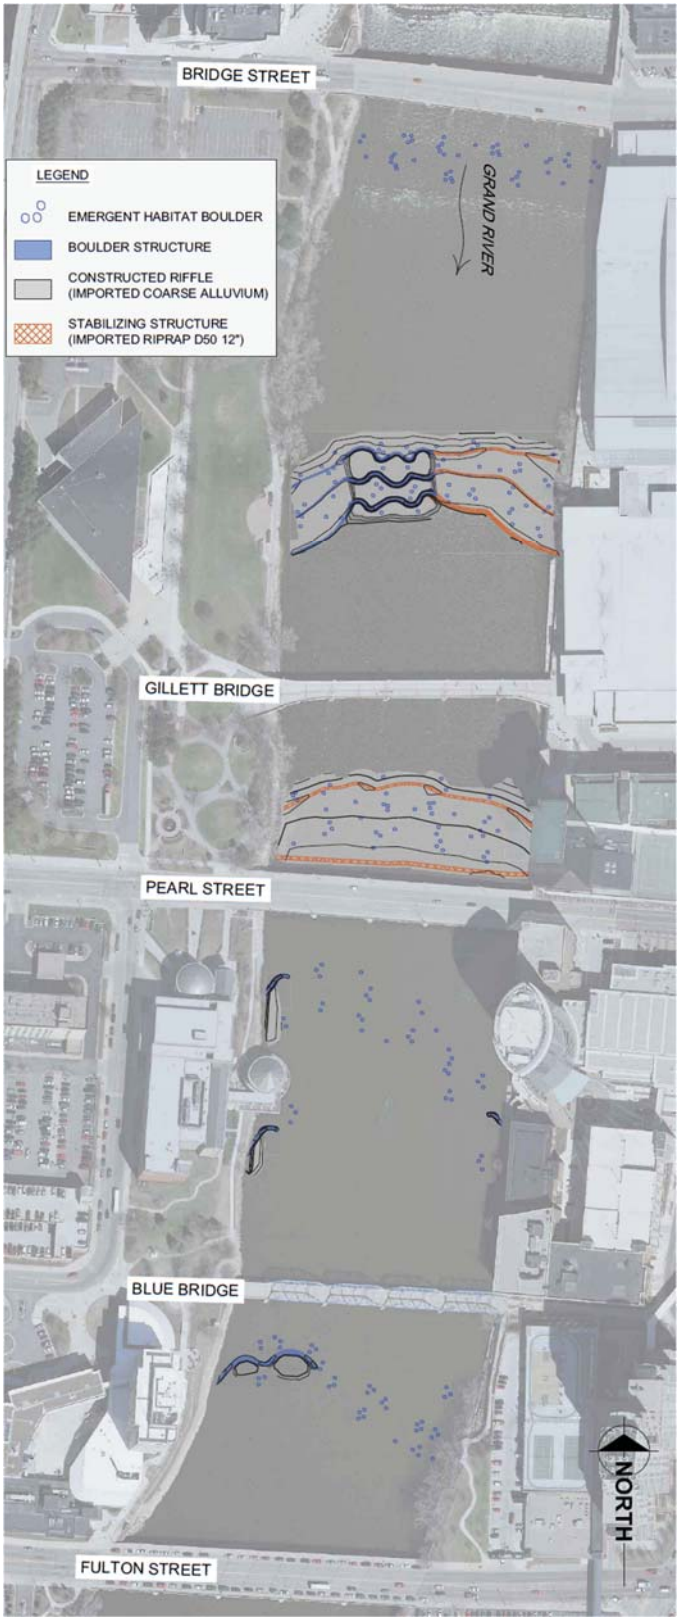

Figure 8: Proposed Substrate Fill Map

3.4. Manning Roughness

The empirically derived parameter, *n*, is the primary user-defined value in the numerical model which affects localized boundary shear stress. Values of *n*, typically termed "roughness" are dependent on the boundary friction of the channel, the resolution of the model, and the depth of flow relative to the substrate size of the bed. The roughness of any one reach of river is unique to the characteristics of the site and determining an *n* value that calibrates modeled channel roughness at the flow rates being modeled is an important part of hydraulic design. Calibration can be achieved by surveying water levels for a range of flow rates throughout the reach for comparison to modeled or calculated water levels. This process was performed on the project reach and a Manning value of 0.03 was determined to calibrate to surveyed water surface profiles under existing conditions during typical flow rates, including the average annual flow rate of 3,900 cfs.

The proposed substrate includes material that is coarser than what currently exists in the channel; therefore, a set of proposed *n* values were used based on proposed substrate size. The *n* values for proposed substrate were based on an investigation report by the USGS in which a series of calibrated *n* values were calibrated for a range of different modeled channels with various grades, substrate size, and flow rates. The data referenced in this investigation report were used to develop equations based on grain size and flow depth to approximate *n* values for various conditions. These findings were used to choose *n* values for modeling proposed substrate within the project reach. The results of this investigation report are presented in Table 6, taken from Blodgett (1980).

Table 6. Manning's roughness coefficient, *n*, for selected values of mean depth and median bed material size (Blodgett, 1980).

Mean depth, d_a (ft)	Median diameter of bed material, D_{50}, in feet

Relationships used in preparing table:

Equation 12 $$n = \frac{0.0926\, d_a^{0.167}}{0.794+1.85 \log d_a/D_{50}} \quad \text{for } 1.5 < d_a/D_{50} < 185$$

Equation 17 $$n = 0.0185 d_a^{0.167} \quad \text{for } 185 < d_a/D_{50} < 30{,}000$$

Table 6 was referenced at flow depths of four feet, which corresponds to when each channel location begins to become submerged by the lower gradient tailwater and not produce as much scour potential. Depending on the specific location of each feature, this occurs at a different flow rate ranging from about 4,000 cfs to 10,000 cfs. 10,000 cfs is approximately the 1-year flood, or ordinary high water. The proposed substrate and selected *n* values used in the SRH-2D model to predict substrate stability and determine appropriate material sizing is presented in Table 7. These values are considered to be conservatively high for evaluating flood flows, which contain larger flow depths. High *n* values also result in relatively high calculated shear stresses. Because shear stress is being used to determine imported substrate sizes, the conservatively high *n* values are considered to be a base level safety factor for substrate stability.

Table 7: Manning *n* values for proposed conditions SRH-2D model

Substrate	D50 (inches)	Manning n Value
Existing/Native Alluvium	Varies	0.03
Imported Fine Alluvium	3	0.041
Imported Very Coarse Alluvium	12	0.061
Imported Boulder	36-48	0.07

3.3. Existing and Proposed Hydraulic Modeling Output Comparison

Proposed modifications to the channel will alter velocity and shear stresses which directly impact substrate mobility. In order to gain perspective on the degree and the locations of increased shear potential, SRH-2D modeling results were compared between existing and proposed conditions. Flow velocity and bed shear stress calculations were made for flow rates ranging from 890 cfs to 31,000 cfs, representing extreme low flows to the 10-year flood. As tailwater elevations increase for larger flow events, the project reach becomes submerged and shear stresses are reduced throughout the project reach with the upstream feature becoming submerged at approximately 13,000 cfs. Maximum values for velocity and bed shear stress were determined by evaluating all flow rates modeled and combining all calculation results at each node within the model for existing and proposed conditions. The existing and proposed maximum value maps were compared to one another to determine locations of increases and decreases. Results are presented in Figure 9. This evaluation was used to help determine proposed substrate sizes and apply a stability factor of safety of 2.0.

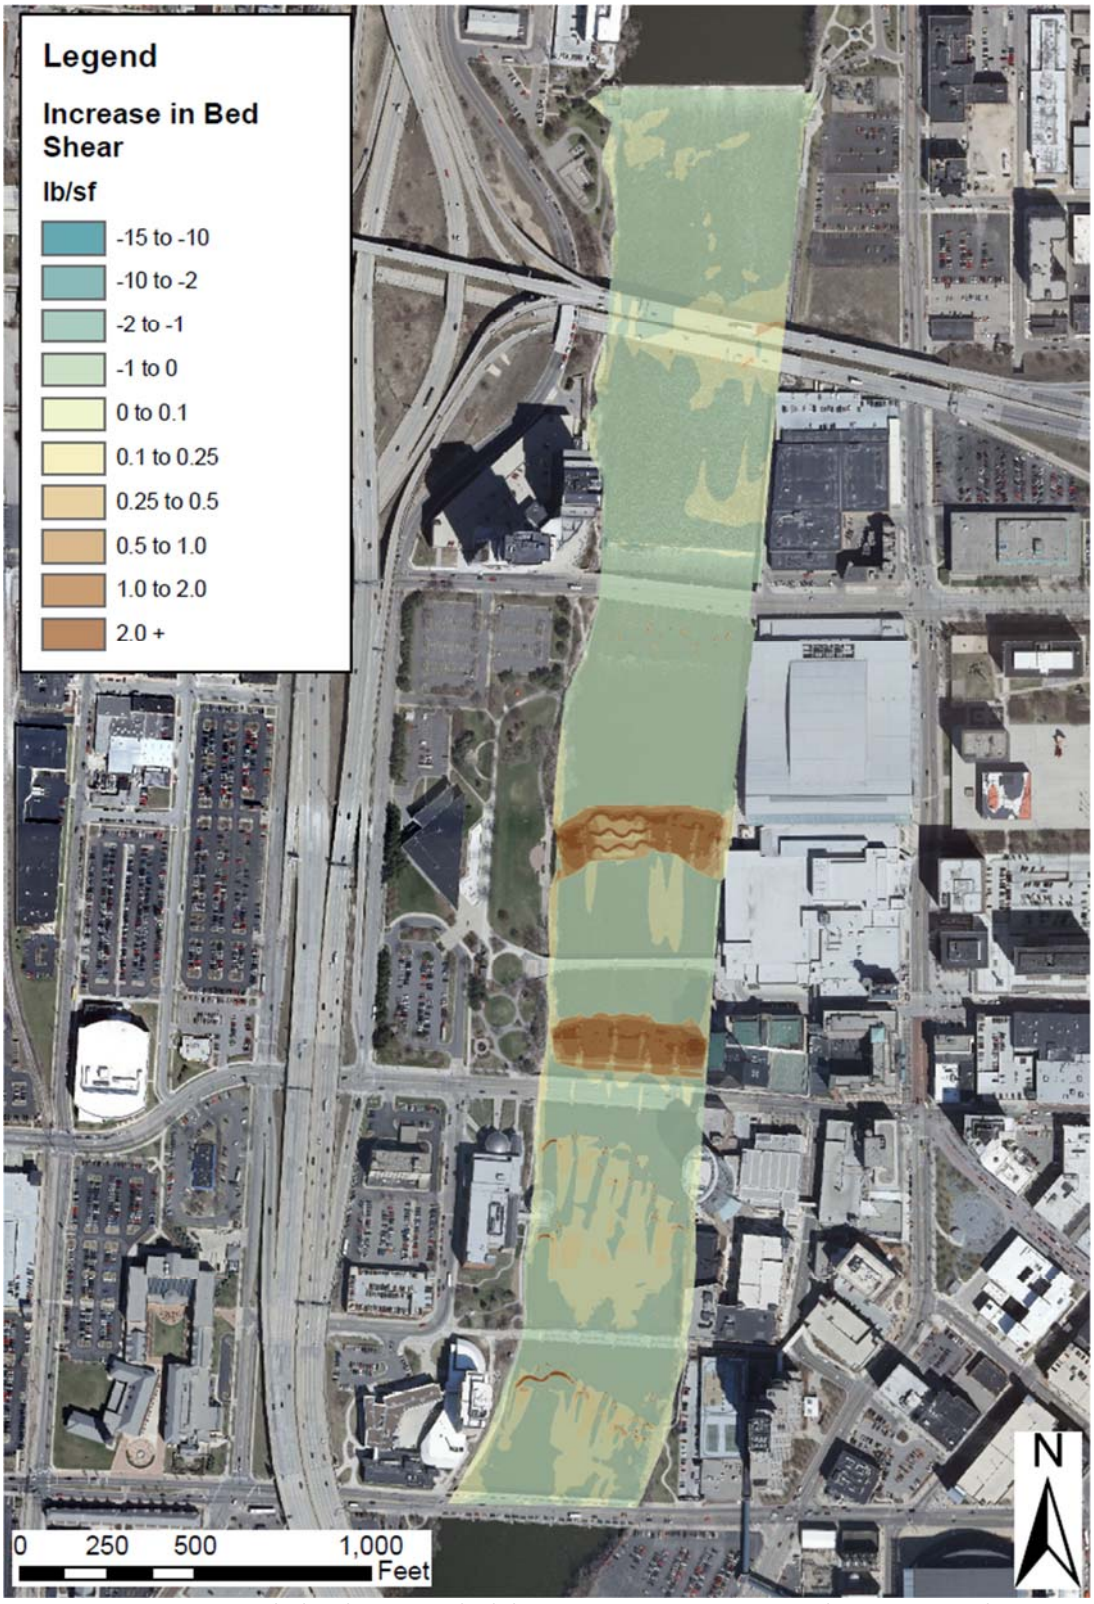

Figure 9: Increases in calculated maximum bed shear stress, comparing proposed to existing conditions

3.4 Substrate Stability Factor of Safety

A factor of safety of 2.0 was applied to the calculated boundary shear stresses to determine proposed substrate size-classes in order to promote substrate stability over the life of the project. Sediment size classes are distributed on a base-2 logarithmic scale; using the identified factor of safety will increase sediment sizes by one discretized classification in Table 4. Identified sizes from the proposed methodology will be set as the d30 of the well-graded imported substrate mixture.

The boulder arch structures will be constructed of placed boulder materials sized to exceed order of magnitude increases in mobilizing forces and account for scour stability and form drag; shear-stress material sizing will be more critical at the general grading of imported alluvium proposed in the construction of the riffles. The control structures and crests of all riffles will be constructed from riprap with d_{50} grain size of 12 inches. Substrate stability is less critical of the proposed grading which are not hydraulic controls and are either upstream or downstream of peak hydraulics; however, a minimum factor of safety of 2.0 has been used to size the proposed fill for these areas as well.

Factor of safety values were calculated over the project reach by dividing the incipient motion critical shear stress of the finished grade particle size by the calculated maximum shear stress predicted by the model over flows ranging from 2,500 cfs to 18,000 cfs, when all features are submerged by the low gradient tailwater.

Figure 10 presents the calculated factor of safety values throughout the project reach. There are limited locations of the channel with calculated factor of safety values slightly below 2.0; this is a result of increased Manning n values over substrate that was sized up to provide a factor of safety of 2.0 based on prior modeling results. The fact that these areas have a calculated factor of safety slightly less than 2.0 is an indication that Manning n values are conservatively high for substrate stability; continuing to increase the substrate size of these areas would also increase the calculated shear stresses, and would result in an over-coarse bed due to conservative assumptions of the Manning roughness parameter. The control structures for all features still contain at least a factor of safety of 2.0 across the entire channel. For these reasons, no stability concerns are anticipated based on substrate sizing, conservative modeling parameter assumptions, and calculated modeling results.

Factor of safety values were also calculated over existing substrate outside the limits of grading. The substrate sampling data collected by Materials Testing Consultants (MTC) in 2017 was used to determine particle sizing of the existing bed. Figure 8 presents a proposed substrate map; all areas without hatching are proposed to remain as native substrate.

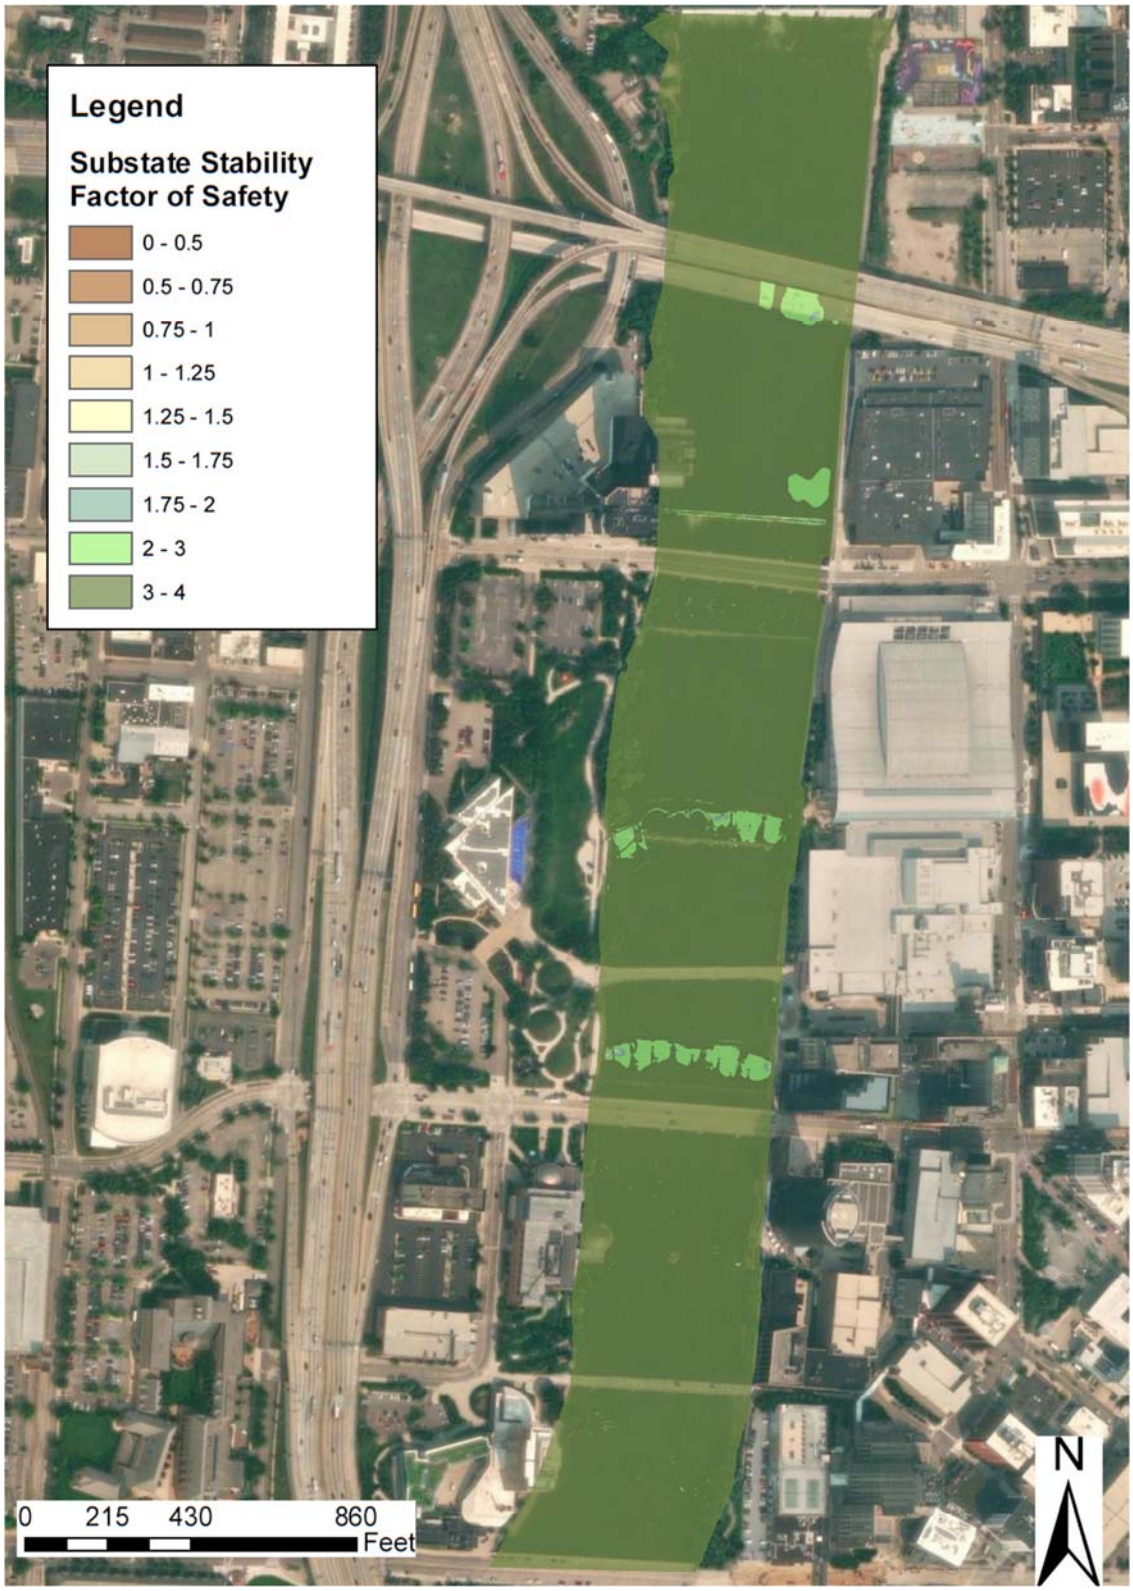

Figure 10: Substrate Stability Factor of Safety Map

3.5 Temporary Construction Conditions

The project is recommended to be constructed primarily in the flowing river without work isolation. Construction access would be provided by a network of low-elevation causeways which would reduce flow depths for construction equipment and provide a stable working pad. These causeways would be constructed of stable imported aggregate that would be removed from the channel after construction. The aggregate material has been sized to remain stable and would not influence flows to create increased scour potential over existing substrates. Therefore, mobilization of substrate is not a concern during these phases of construction, when no work isolation is present in the channel.

The west half of the proposed improvements at the Dam 2 location are proposed to be constructed within a cofferdam system. The cofferdam system, proposed to be constructed of aggregate bags, has been minimized in footprint area and height and would be overtopped at approximately 4,000 cfs. The cofferdam is anticipated to be required for approximately three weeks during July or August and would remain in the channel during any overtopping flows.

During isolation, the area of channel to the east of the cofferdam would experience increased scour potential resulting from the constriction of flow and increased flow velocities around the work isolation area. Maximum bed shear stresses in this location of the channel were calculated during a flow rate of 7,500 cfs, when shear stresses reach approximately 1.1 lb/sf. This condition may have the potential to mobilize up to 2.5-inch diameter substrate (Table 4). Estimated substrate sizes in this area of the channel are 2.7 to 3.4 inches (Table 2), indicating high likelihood that substrate would remain stable during peak scouring conditions if they were to occur. Peak scouring conditions were modeled during 7,500 cfs, which has a very low likelihood of occurrence during the months of July and August, with a daily percent chance of occurrence of 1.7%. Figure 11 displays a factor of safety map against substrate mobility during isolated conditions and peak scouring conditions. Factor of safety of less than 2.0 exist directly downstream of the isolation area in a very localized area.

Results indicate low likelihood for substrate mobility. However, if substrate were to mobilize during construction, modeling results indicate that it would deposit relatively quickly downstream of the isolation area, once the river returns to full flow width and calculated shear stresses are reduced. Any deposited substrates within the project reach would be monitored and could be addressed if needed during construction.

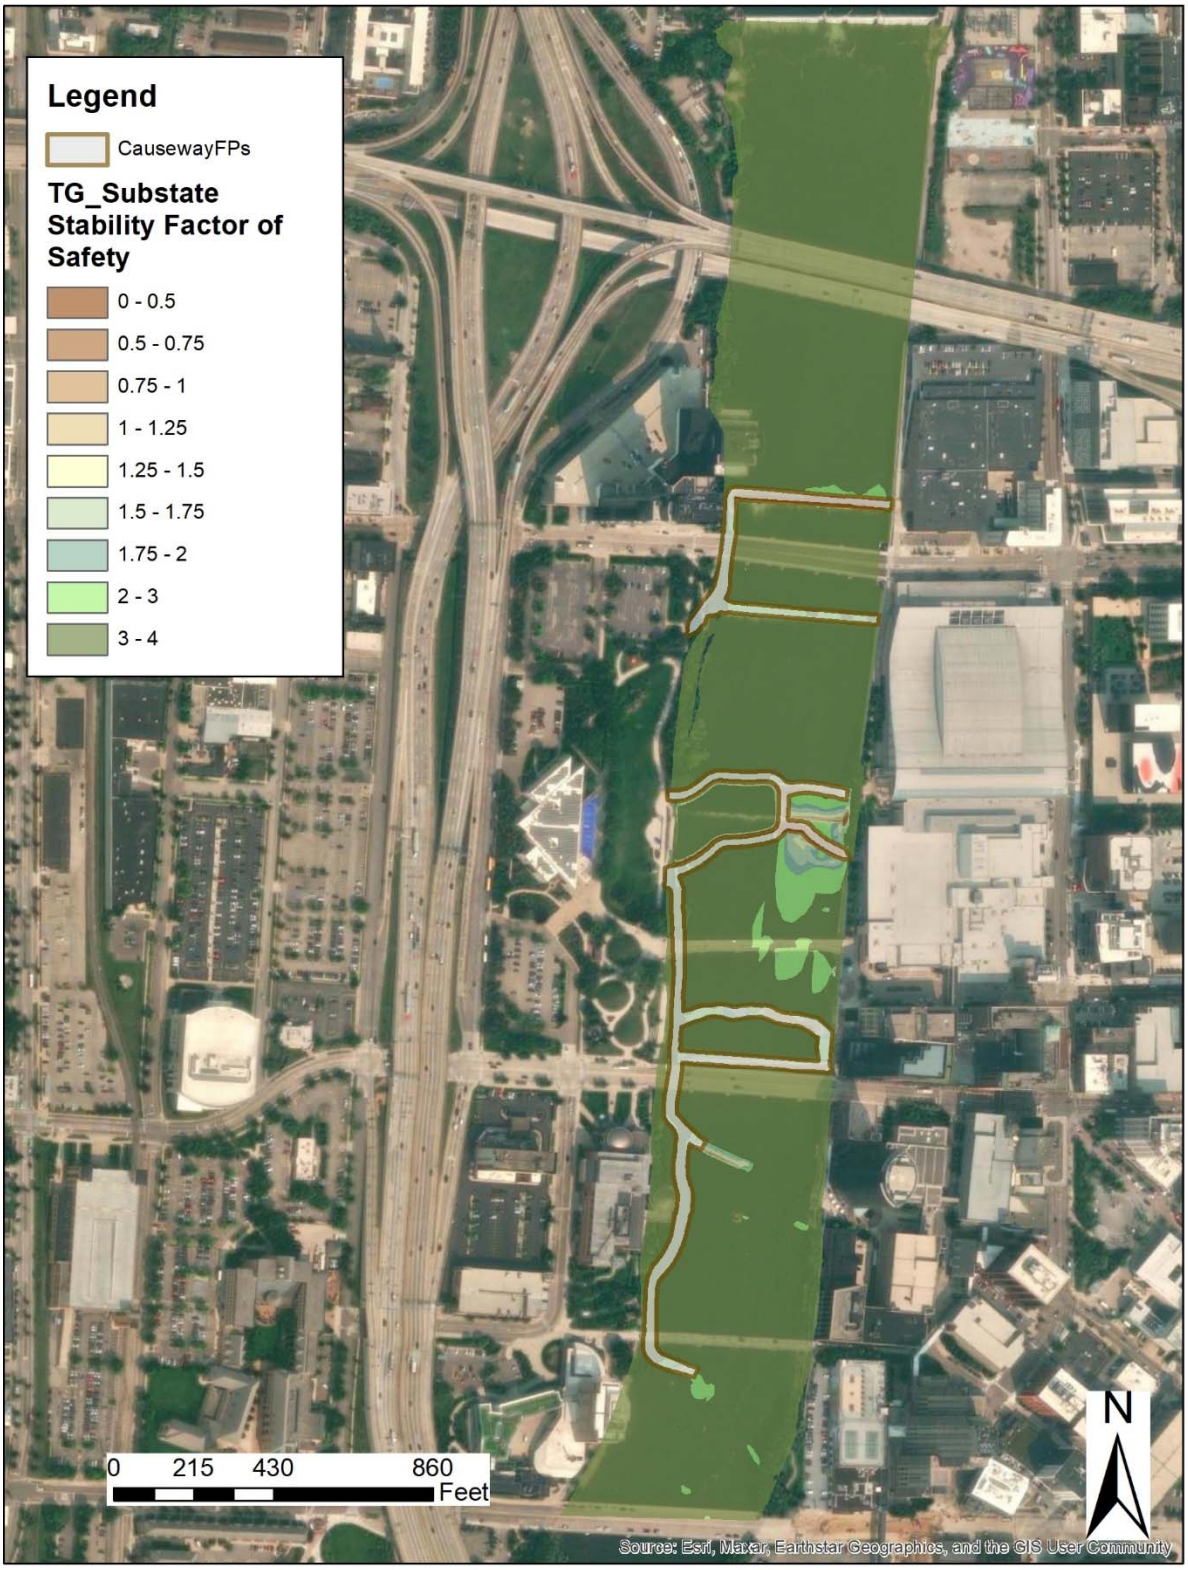

Figure 11: Substrate Stability Factor of Safety Map for temporary conditions

Section 4 – Transient Deposition and Scour

Local deposition and scour are transient functions of a natural channel which establishes a dynamic equilibrium between variable hydrology, the channel substrate, inflowing suspended sediment, and the hydraulics of the river. Transient deposition of sand naturally occurs in rivers with variable hydraulics, which are present in a rapid reach. This is due to the spatial and temporal variability in transport capacity that results from diversifying the bed material and elevation. These processes are not indicative of aggradation or degradation. Aggradation is the trend of continual deposition over time and throughout an entire cross section due to the inability of a reach to transport the inflowing sediment load. Aggradation of the inflowing sand sediment load is not anticipated due to the increased energy gradient of the flowing water throughout the project reach. Degradation results when the sediment transport capacity of the channel continuously mobilizes substrates over time. Avoiding ongoing degradation as a result of the project was done through sizing substrate materials that resist transport and by establishing grade control elevations of the hydraulic features to elevations high enough to minimize and avoid increased shear stresses on the existing channel bed upstream of the project.

A goal of the project is to enhance aquatic habitat. By doing so, flow diversity will also be enhanced, resulting in changes to flow depths, magnitude and direction of flow velocity, and substrate. Local deposition and scour of the bed load are part of maintaining diversity in the gradation of substrate. Local deposition and subsequent scouring are anticipated in certain areas of the proposed grading. The proposed channel is designed to progress from initial post-construction condition to reach a dynamic equilibrium of deposition and scour, promoting optimized natural river function.

The Grand River may be generalized as a sand bed system, transporting a total load of sand during moderate and high flows. Based on sampled bed substrate and bathymetric survey of the channel, sediment transport equations indicate that sand bedload initiates into the project reach from upstream at flow rates above 3,500 cfs. Transient deposition and subsequent remobilization of supplied load occurs in limited locations under existing conditions; the proposed hydraulics will change the locations of transient deposition. Transient deposition areas also exist upstream of 6th Street Dam; sand is deposited during moderate flow rates (3,500 cfs to approximately 10,000 cfs) and mobilized again during high flows (10,000 cfs and above). Under existing conditions, the majority of the sand supplied to the project reach transports beyond the downstream project boundary (Fulton Street). Transient deposition at localized low-velocity areas have been observed and modeled.

The complexity of the proposed design has potential to increase the number of locations of transient deposition. An evaluation of the proposed hydraulics has been completed to further evaluate locations, deposition rates, and frequency of remobilization.

4.1 Modeling Results

Individual potential transient deposition areas were identified based on the proposed hydraulics of the river. Each area was then evaluated by comparing flow velocity, the size of the deposition area, and fall velocities associated with a range sand particle size classes to determine the likelihood of local deposition occurring. The hydraulics associated with a flow rate of 3,500 cfs were used in the analysis; this is because 3,500 cfs is the lowest flow rate at which sand was determined to be supplied from upstream into the project. By using hydraulics associated with the lowest flow rate with an inflowing sand load, minimum depths and velocities were used to determine settling times for conservative estimations. The flow rate at which any sand deposited would be remobilized into the bedload again

was determined based on threshold shear stresses for sand. The results of this analysis are presented Figure 12 and Table 8. In general, identified areas are anticipated to exhibit local deposition of supplied bed load; however, these areas were modeled to remobilize at flow rates at or below approximately 10,000 cfs.

Volumetric sediment discharges in cfs were calculated for flow rates in the Grand River up to 10,000 cfs using bedload equations and the sampled bed gradation upstream of the project. During flow rates at and above 10,000 cfs, velocities become high enough to keep inflowing sand in suspension and to scour temporarily deposited sand. Using inflowing sediment discharge rates, an estimated maximum daily deposition depth was calculated for each deposition site, based on the specific site dimensions. The results of this evaluation are presented in Table 8. The values presented in Table 8 assume fall velocities associated with coarse sand (0.5 mm). Deposition times for each deposition area were calculated based on flow depth and compared to available depositional time as a factor of flow velocity and the length of each deposition area. Fall velocities associated with coarse sand assume 100% of the supplied sand load to a given transient deposition area settles out. Results are considered conservatively high for this reason. Some of the deposition areas would not experience any deposition if fall velocities associated with fine sand (10 mm) are used. Daily deposition depth values should be referenced with the second column in Table 8, which estimates the flow rate that will remobilize the sand bedload.

Transient sand deposition was also evaluated at areas under existing conditions and similar deposition rates were predicted by the modeling results. Based on existing conditions SRH-2D modeling results, medium to coarse sand is predicted to settle on the existing bed in fewer areas than the proposed conditions, but with similar rates and daily depth accumulation.

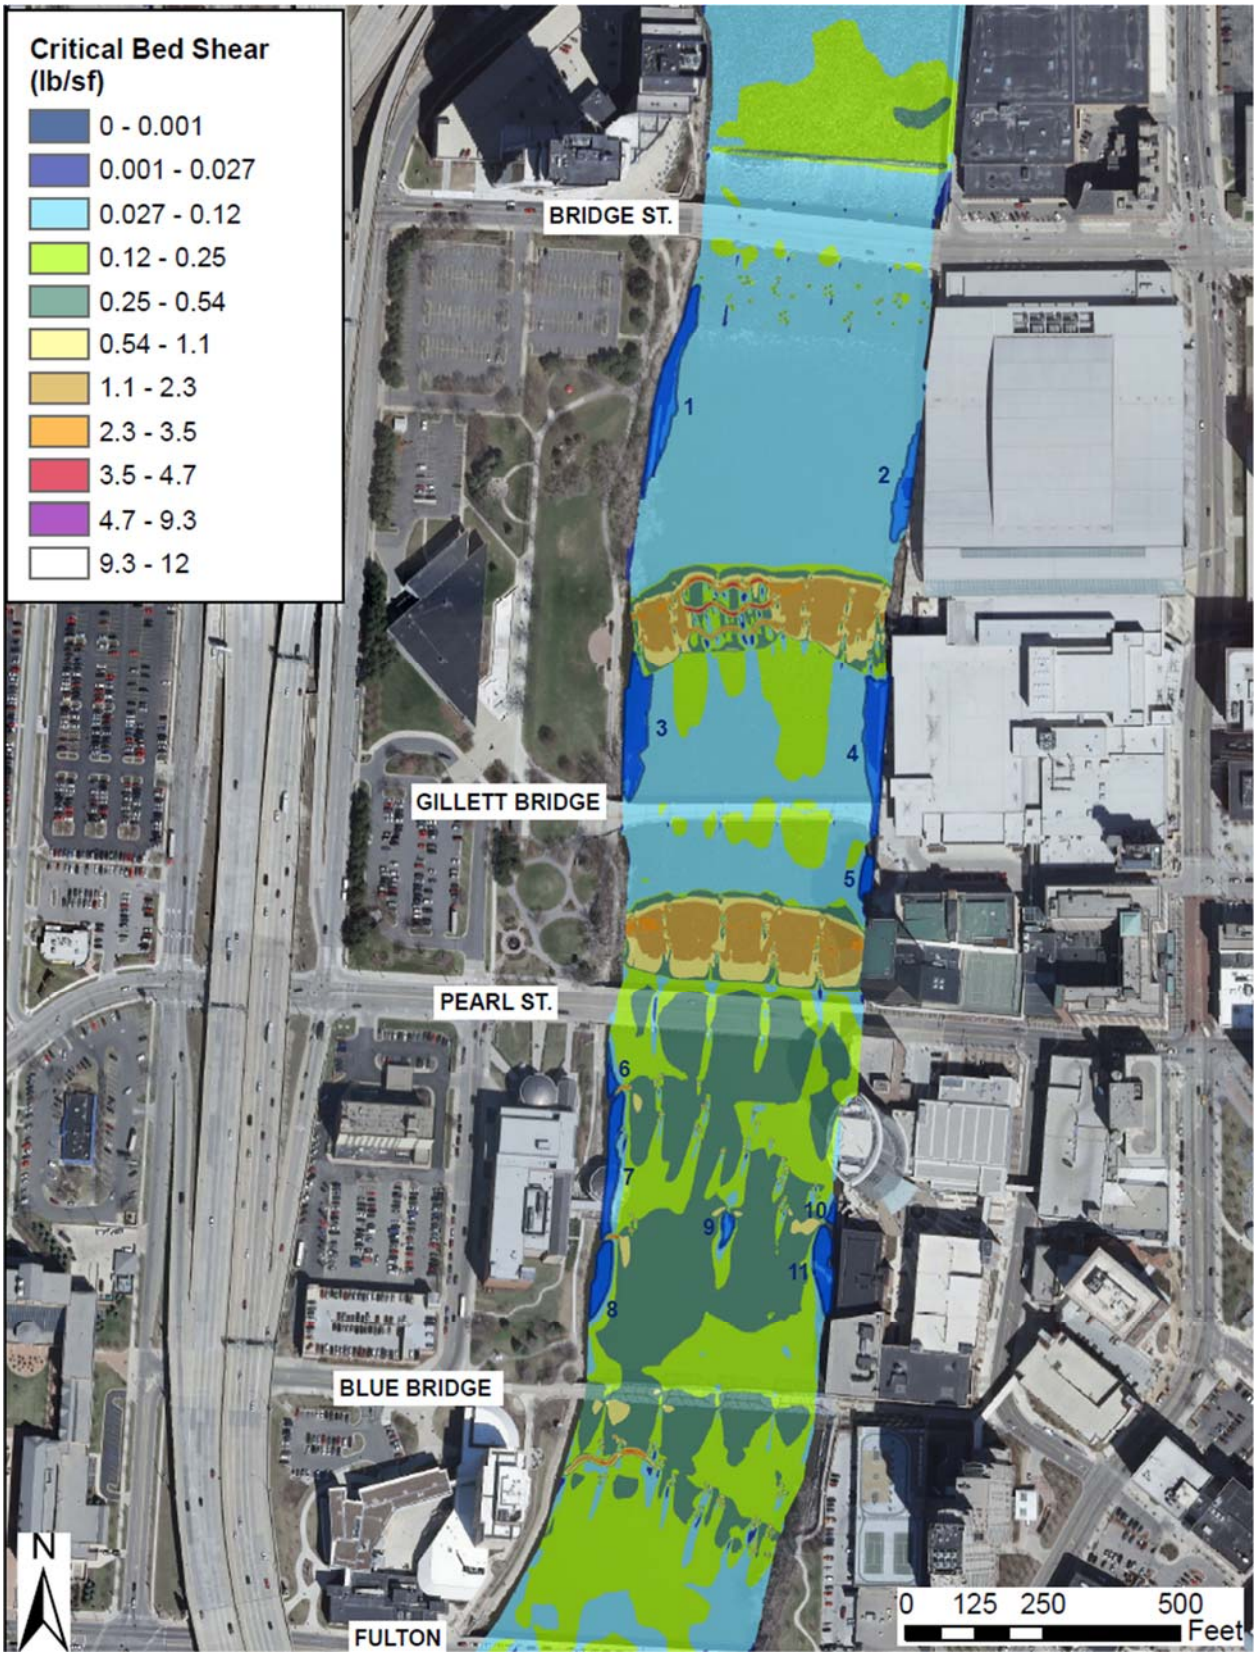

Figure 12: Transient deposition area location key.

Table 8: Transient deposition analysis

Proposed Conditions

Transient Deposition Area	Scouring flow rate (cfs)	Average flow depth at 3,500 cfs (ft)	Settling time for coarse sand (seconds)*	Average flow velocity at 3,500 cfs (ft/s)	Flow length of pool (ft)	Estimated maximum daily deposition depth (inches)
1	7,500	2.8	12.2	0.9	377	0.7
2	7,500	4.4	19.2	1.3	219	1.2

Fulton - US131 west bank	2,500	5	21.8	2	450	0.0

** Assumes no vertical flow velocity*

The transient deposition of bedload would function similarly under proposed conditions as existing conditions; however, due to the increased hydraulic diversity, as well as substrate size necessary to provide a naturally functioning rapid environment, an increase in number of locations of transient deposition is anticipated under proposed conditions. Similar to existing conditions, sand sized deposits would periodically be remobilized and transported beyond the downstream project boundary and assimilated in the river system during regular high flow events. Once the channel is exposed to complete hydrologic cycles post construction, a dynamic equilibrium between hydraulics and the channel substrate is anticipated and deposition areas would gradually transition to coarser substrate near annually higher velocity areas of the channel.

Section 7 – Conclusion

Long-term aggradation or degradation through the project reach is not anticipated to occur due to the transport limited supply reach, the relative increased energy throughout the project, and proposed stable gradation of imported/placed substrate. The project would function as a threshold reach, conveying the inflowing sand sediment loads to the downstream reach over a typical annual hydrograph. No long-term changes to inflowing or outflowing sediment are proposed or anticipated. The risk of long-term degradation will be minimized and avoided by importing material into high energy areas that is large enough to resist mobilization across all flow rates and anticipated hydraulic stress. Two-dimensional hydraulic modeling and industry standard sediment transport equations are among the tools utilized to locate these high energy areas.

Proposed improvements and substrate enhancement have been designed and evaluated to maintain a minimum factor of safety against substrate mobility of 2.0 based on critical shear and incipient motion analyses.

The potential for increased bed mobility during construction has also been evaluated. Although the river would have increased potential to mobilize substrate during construction, substrate sampling data and hydraulic modeling results indicate a low probability of sustained mobilization and a high likelihood that mobilized particles would deposit within the project reach if they do mobilize.

Local deposition and scour may occur periodically, and the project design allows for some localized changes in the bed elevation and composition to develop a dynamic equilibrium. While the urban project reach will never be an entirely natural channel, the developed dynamic equilibrium state allows natural channel functions to occur. Dynamic channel equilibrium would allow for natural channel function while maintaining designed hydraulics. The local deposition of sand from the inflowing bedload has been shown to re-mobilize at flow rates at or below approximately 10,000 cfs which occur each year on average; therefore, impacts to flooding from ongoing local aggradation would be avoided.

DRAFT

1. EXECUTIVE SUMMARY

Bridge piers within the Grand River at Grand Rapids, MI have been evaluated under existing, post-project, and temporary construction conditions associated with the Grand River Revitalization Lower Reach Project (Project). These evaluations indicate that the post-project conditions would result in changes to scour potential at the bridges within the project area. Changes to scour potential have been concluded to result in similar scour patterns at bridges as compared to existing conditions, resulting in low risk to pier stability. Modeling results demonstrate an increase in scour potential resulting from higher calculated stream power at I-196. However, calculated increases in stream power remained below critical stream power to induce scour beneath the bridge, as calculated by the MDOT scour evaluation performed in 2016 (MDOT, 2016). Refer to section 4 for a complete discussion.

Temporary conditions models identified increased pier scour potential at Gillett Pedestrian Bridge and Pearl Street Bridge that would occur during construction. Evaluations and conclusions for each bridge are discussed herein.

2. INTRODUCTION

Proposed restoration efforts as part of the Project will reconfigure the existing Grand River in Grand Rapids, Michigan from a grade-controlled backwater system to an enhanced, diverse flowing rapid environment. Four existing grade-control structures (channel spanning, low-head “beautification” dams) are proposed to be replaced with stable river enhancements that provide benefits for recreation, navigation, habitat, and aesthetics. Figure 1 illustrates the bridges spanning the Grand River through downtown Grand Rapids and an aerial overview of the site. The construction area is indicated with the dashed orange line.

The project has implications for hydraulic conditions around the foundations and substructure of bridges crossing the Grand River. Local scour depths at the bridges are a function of these hydraulics. Project impacts on bridge pier and abutment scour are analyzed and discussed in this report. Bridge infrastructure geometries, orientation, and channel bed substrates are detailed for each structure. Hydraulic models have been developed to quantify parameters which affect local bridge scour. Parameters are quantified for existing, proposed, and temporary construction conditions. The full range of flows historically present at the project site are considered.

Hydraulic Engineering Circular No. 18 (HEC-18) provides guidelines for evaluation of scour at river-spanning bridges. All analyses performed herein follow HEC-18 guidelines, which are the current state-of-practice for bridge scour evaluation.

DRAFT

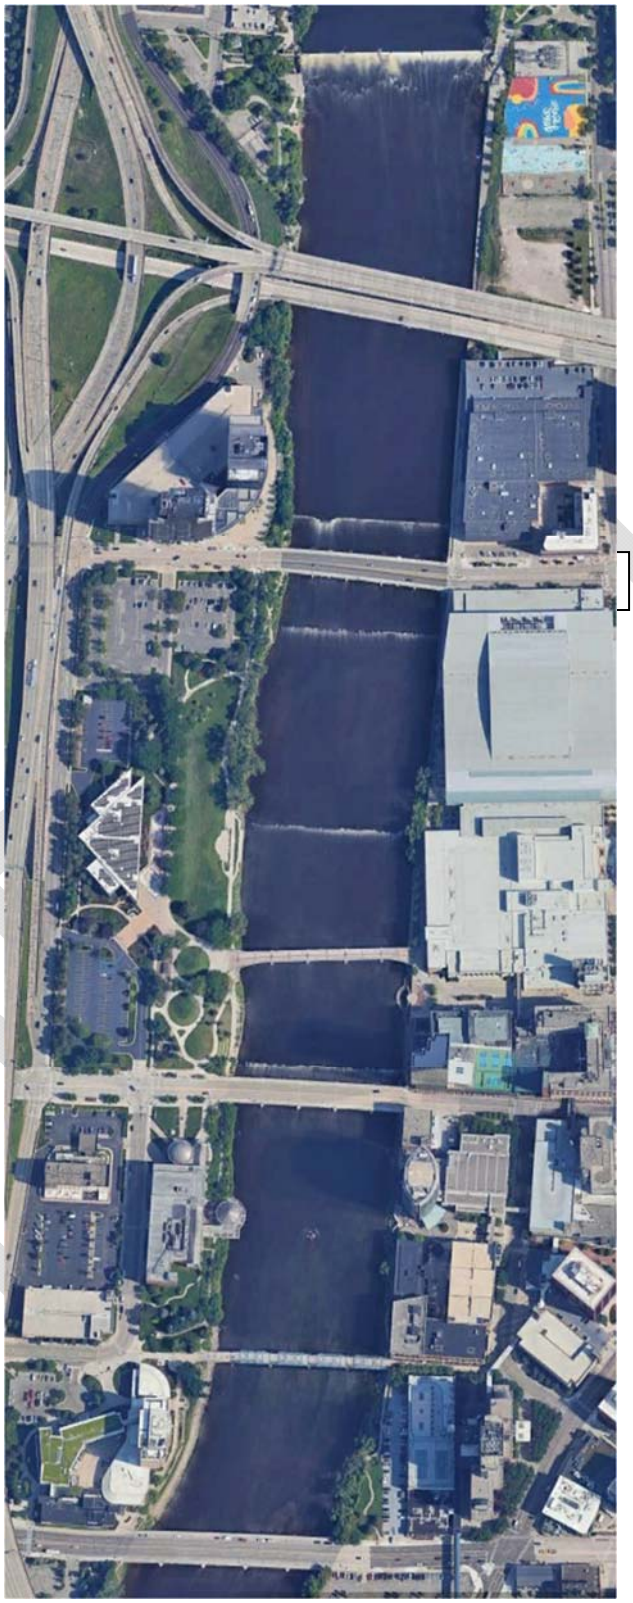

Figure 1. Overview of project area (orange) with identified bridges (Google, 2023)

3. TOTAL BRIDGE SCOUR

Scour at bridges comprises three components: 1) long term degradation of the riverbed, 2) contraction scour at the bridge opening, and 3) local scour at the bridge abutments and piers.

Long Term Degradation

Long-term degradation is caused by reach-scale changes to the river system and can be incited by natural or human-made causes. Degradation scour does not typically initiate from a bridge crossing itself, but bridges may be affected by it. An example would be a downstream head-cut migrating upstream which undermines a foundation. Other instances may include substantial changes to the system hydrology or sediment discharge. The Grand River throughout the project exhibits characteristics of vertical stability. The existing system is a threshold channel which does not exhibit hydraulics capable of bedload transport. The river above and below Grand Rapids is a very mildly sloped channel, while the channel within the project area is relatively steeper. Increasing discharges create tailwater conditions which submerge project area elevations at high flow rates. This submergence acts to reduce velocities and boundary shear stresses and serves as a degree of protection against bed mobilization.

Contraction scour

Contraction scour occurs where bridge geometries or abutments encroach upon the river channel, creating a localized narrowing of the channel cross-section and acceleration of flow. Accelerated flow increases sediment transport and scour potential. The Grand River throughout the project area has primarily been confined between concrete floodwalls and levees. Bridges span the entire river from floodwall to floodwall. Thus, there are no approaches which encroach the floodplain and there are no instances where the river flow is constricted through a bridge opening from a wider floodplain. Contraction scour is not present under current conditions within the project area and is not affected by project actions.

Local Scour

Local scour occurs around bridge foundations, specifically abutments and piers. The primary mechanism for this type of scour is from localized flow acceleration around bridge structures and the resulting formation of turbulent currents at the base of abutments and piers. Abutments within the project area are generally contained within flood walls and do not interact with the flow. Designed river-habitat improvements incorporate grading which produces hydraulic conditions that avoid concentrated hydraulics in the vicinity of bridge infrastructure. However, project actions may alter hydraulic characteristics which drive local pier scour at specific flow rates.

Of the three main scour components, long-term degradation, contraction scour, and local scour, potential for long-term degradation was identified at I-196 and the local scour generated by the bridge piers was identified as a potential area of concern within the project area and have been evaluated and are discussed herein.

DRAFT

4. LONG-TERM DEGRADATION POTENTIAL AT I-196

Within the project area, four low-head concrete grade-control structures between Fulton Street and I-196 (low-head dams) act to locally dissipate energy and maintain mild hydraulic gradients between. The complete grade-control function of low-head dams 1, 2, and 3 would be replaced with constructed riffles and boulder arches, designed to remain stable and distribute the energy dissipation along the channel profile.

However, the grade control function of low-head Dam 4 is proposed to be removed without equivalent replacement. Only ~25% of the grade control function of Dam 4 is proposed to be replaced by the project. This is due to the project constraint of avoiding and minimizing increases in modeled tailwater elevations at 6th Street Dam (referred to as 4th Street Dam in some documents) as a means to avoid impacts to the effectiveness of the dam as a barrier to sea lamprey. Modeled conditions were based on conservatively high Mannings 'n' values for the purpose of being conservative in water surface elevation predictions. However, conservatively low Mannings 'n' value models predict post project conditions will establish higher velocities and increased scour potential of the existing bed upstream of the project, between 6th Street Dam and Bridge Street. These models reveal the potential for hydraulic jumps to form under I-196. This hydraulic change has been evaluated and compared against substrate sampling data (MTC, 2017) and existing core sampling and scour evaluations (MDOT, 2016). Increases in calculated stream power indicate that there may be increased potential for long-term degradation of the riverbed near I-196 under post-project conditions.

Rapidly varied flow of a hydraulic jump can be highly erosive. The erosive potential of a hydraulic jump is based on the theory of Stream Power, wherein the entire energy dissipation of the hydraulic jump is assumed to be conservatively applied to the channel bed in equation 4.7 (HEC-18):

Equation 4.7:

$$P = \gamma q S_f = \gamma q(\Delta E)$$

where: P = Instantaneous stream power, (W/m2) ; γ = Unit weight of water, (9,800 N/m3) ; q = Unit discharge, (m3 /s per meter width) ; S_f = Slope of the energy grade line, ft/ft (m/m) ; ΔE = Energy loss per unit distance in direction of flow, ft/ft (m/m)

As part of their scour evaluation for the recent I-196 pier extension project, AECOM calculated the critical stream power necessary to initiate scour though erodible bedrock, which is a function of bedrock properties, at each bridge pier. These critical stream power calculations were referenced to compare calculated peak stream power against to evaluate potential of erodibility through long-term degradation. The lowest critical stream power calculated from MDOT findings for the 2016 scour report was 8,739 W/m^2; erodibility and factors of safety are all evaluated herein against this value as a conservative assumption.
The reason Equation 4.7 was evaluated is that energy loss can be concentrated at a single point in a hydraulic jump. Because the proposed changes of the project lower the grade control elevation downstream of I-196, conservative assumptions were modeled to evaluate maximum energy losses under the bridge. This was done by first running an SRH-2D model with Manning n values for the entire proposed grade mesh down to 0.02 (lower than calibrated values) as a way to evaluate minimum potential tailwater elevations

downstream of the bridge, and therefore maximum potential energy losses in the reach, which is concentrated under the I-196 bridge. This model calculated super-critical flows in various spots beneath the bridge at several flow rates, which were not calculated in the model with higher Manning n assumptions.

To assess the potential increased scour potential resulting from hydraulic jumps which may occur beneath the bridge, conservative assumptions were also placed on the ΔE term of the equation. To evaluate the potential for a hydraulic jump occurring, the entire headloss from upstream to downstream of super-critical flows to was assumed to be spent over 1 meter of channel bed for all flow rates that calculated super-critical flow conditions (using the 0.02 Manning model). This is the reason calculated stream power in Table 1 are higher for flow rates up to 10,000 cfs, all of which calculated areas of super critical flow under the low Manning assumption model. Some energy of a hydraulic jump may be expended in turbulence rather than applied to the substrate, for this reason as well as the conservative assumptions, the results in Table 1 are considered conservatively high.

The calculated stream power and resulting factors of safety against scour are compared for Equation 4.7 in Table 1. Conservative modeling and calculation assumptions show that the project changes have potential to increase scouring conditions beneath I-196; however, calculated stream power remain below critical stream power calculated by MDOT by a minimum factor of safety of 2.0.

Table 1: Estimation of Scour due to Hydraulic Jump, using Equation 4.7 of HEC-18 Manual

Flow Rate (cfs)	Existing Conditions		Proposed Conditions	
	Stream Power (W/m2)	Factor of Safety Against Scour(1)	Stream Power (W/m2)	Factor of Safety Against Scour*
3,900	109	80	2,244 (2)	4
5,000	184	48	2,877 (2)	3
7,500	446	20	3,836 (2)	2
10,000	734	12	4,475 (2)	2
13,000	1,182	7	1,932	5
18,000	1,542	6	1,542	6
26,000	1,727	5	1,727	5
31,000	2,005	4	2,005	4

(1) Minimum critical stream power calculated from MDOT 2016 scour report (8739 W/m^2) divided by calculated stream power.

(2) Modeled areas of super-critical flow.

5. POTENTIAL FOR LOCAL PIER SCOUR

Mean-flow velocities, turbulent velocities, boundary shear stresses, and stream power at bridge piers are influencing factors for local scour. The extent of scour is dependent upon pier shape, flow characteristics, and local bed substrate. Figure 2 illustrates a profile schematic of pier scour hydraulic parameters, flow distributions, and typical scour geometry.

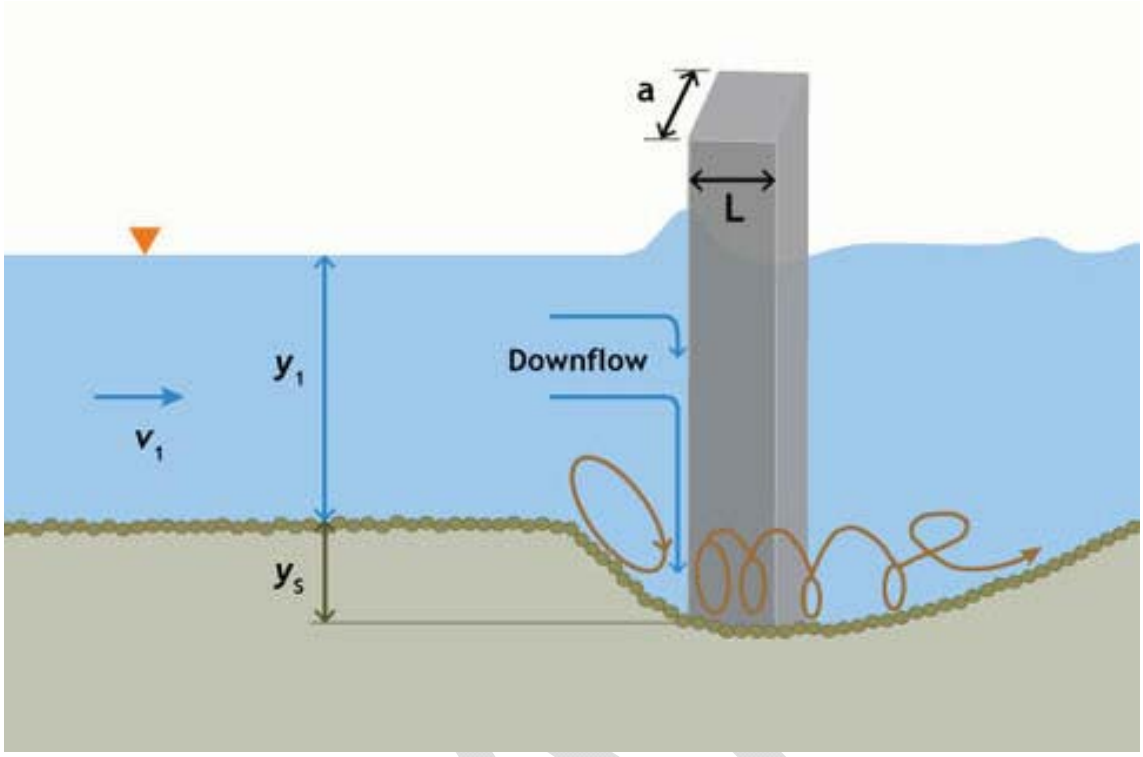

Figure 2. Definition sketch for pier scour (FHWA, 2012)

Richardson and Davis (2001) developed a relationship to estimate bridge-pier scour using sand-bed laboratory flume data presented as Equation 1.

$$\frac{y_s}{y_1} = 2K_1K_2K_3K_4 \cdot \left(\frac{a}{y_1}\right)^{0.65} Fr_1^{0.43} \qquad (1)$$

where:
y_s = estimated scour depth [L];
y_1 = approach flow depth [L];
a = pier width [L];
Fr_1 = approach Froude number;
K_1 = correction for pier shape;
K_2 = correction for flow angle of attack;
K_3 = correction for bed condition

The parameters of Equation 1 affected by proposed project actions include scour depth (y_1) and approach Froude number (Fr_1). Remaining parameters, which include the pier shape (K_1), pier width (a), flow angle of attack (K_2), and bed condition (K_3) are based on existing pier geometries and localized substrates which are not significantly influenced by proposed alterations at flows resulting in the greatest scour potential. Parameters of Equation 1 were identified for each of the bridges by a prior consultant as part of the Grand Rapids Flood Protection System Project.

Equation 1 estimates scour in sand bed systems with D_{50} particle sizes less than 2 mm and D_{95} less than 20 mm. Substrate sampling within the project area and visual observation indicates that the reach would be considered a coarse-bed system (MTC, 2017). For coarse-bed systems, Equation 1 is multiplied by a correction factor, (K_4) for bed armoring. K_4 values range from 0.4 when the velocity upstream of the pier is less than what is required to mobilize the particle size at the pier to 1.0 for sand-bed systems with no bed armoring. The substrate in the reach has been sampled and surveyed within the main channel near proposed grading; however, less detailed information has been able to be collected in the immediate vicinity of each bridge pier. Because the evaluation presented here is a relative comparison and calculated scour depths are only being evaluated relative to existing conditions, a representative value of $K_4 = 0.7$ has been assumed for all scour depths calculations for existing, proposed, and construction conditions to evaluate areas of increased scour potential resulting from proposed actions. Absolute values for calculated scour depths are not considered accurate and all conclusions are based on relative changes in scour potential compared to existing conditions. Table 1 summarizes scour parameters of Equation 1, and general substrate characteristics, d_s, in the bridge vicinity.

The project would not have an impact on hydraulics upstream of 6th Street Dam or downstream of Fulton Street Bridge; therefore, only bridges between Fulton Street and I-196 were evaluated.

Table 2. Bridge-scour parameters

Location	Pier Width, a (ft)*	K_1	K_2	K_3	K_4	d_s
I-196 WB	14.0	1.0	1.0	1.1	0.7	bedrock
I-196 EB	7.4	1.0	1.0	1.1	0.7	bedrock
Bridge St	9.5	1.0	1.0	1.1	0.7	cobble
Gillett Bridge	7.0	1.0	1.0	1.1	0.7	fine cobble
Pearl St	8.0	1.1	1.1	1.1	0.7	coarse cobble
Blue Bridge	8.0	1.1	1.0	1.1	0.7	coarse cobble
Fulton St	9.0	1.1	1.9	1.1	0.7	coarse cobble

* Maximum pier width

Existing, post-project, and temporary construction conditions were first evaluated using one-dimensional hydraulic modeling (HEC-RAS), which complies with current engineering standards and provides data most readily used in the HEC-18 methods. Bridge-pier scour risk typically increases with rising flow rates and associated velocities and flow depths. Flood flows ranging from the 2-year flood (18,000 cfs) up to the 500-year flood (65,000 cfs) were modeled for the existing, post-project, and temporary construction conditions using HEC-RAS. The modeled flow rates and respective return intervals are presented in Table 3.

The most recent large flow event that all bridges have been subjected to in their presently reported configuration is 35,100 ft^3/s. This flood flow occurred on 4/21/2013 and corresponds to a return rate of approximately 23 years.

Table 3: HEC-RAS Modeled Flow Rates

Flow Rate (cfs)	Return Interval
18,000	2-yr
26,000	5-yr
31,000	10-yr
38,000	25-yr
44,000	50-y
50,000	100-yr
65,000	500-yr

5.1 POST-PROJECT CONDITIONS SCOUR

The first evaluation performed was to evaluate flood flows using the HEC-18 procedure (Equation 1) to compare calculated scour depths. Existing and post-project conditions were hydraulically modeled using the Effective HEC-RAS, as provided by Fishbeck with the approved CLOMR models included on August 4, 2023 and detailed in the Hydraulics Report (RiverRestoration, 2024). The methodology for bridge pier scour analysis used extracted hydraulic data from the upstream bridge cross section to perform scour calculations using Equation 1. Table 4 presents calculated scour depths under post-project conditions along with relative percent increases compared to existing conditions in parenthesis. The calculated depths are considered approximate, and this evaluation is only meant to be a relative comparison to existing conditions.

Results of one-dimensional existing and proposed flood conditions modeling indicate that relative differences between maximum calculated scour depths are on the order of modeling accuracy. Peak scour depths were calculated at the 500-yr flood across all locations and maximum increases in calculated scour depths during any flow rate were less than 0.5%, indicating minimal effects to large flow events, which are typically the largest scour-producing flows.

Table 4: Calculated post-project conditions scour depths and percent increase compared to existing conditions.

	Calculated Scour Depth in Feet (Percent Increase)						
Bridge	**2-yr**	**5-yr**	**10-yr**	**25-yr**	**50-yr**	**100-yr**	**500-yr**
I-196 WB	12.3 (-0.1%)	12.8 (0.1%)	12.9 (0.2%)	13.2 (0.4%)	13.3 (0.3%)	13.2 (0.3%)	13.5 (0.4%)
I-196 EB	7.2 (-0.1%)	7.7 (0.1%)	7.9 (0.2%)	8.1 (0.2%)	8.3 (0.3%)	8.3 (0.3%)	8.6 (0.4%)
Bridge Street	8.3 (-0.7%)	9 (-0.4%)	9.4 (-0.2%)	9.7 (0%)	10 (0%)	10.1 (0.1%)	10.6 (0.1%)

DRAFT

5.1.1 PIER SCOUR IN ERODIBLE ROCK (I-196 CROSSING)

The I-196 bridge crossing is within the area of channel, upstream of the proposed changes, that may experience increased scour potential from the hydraulic changes under post-project conditions. It also sits on exposed, or very shallow bedrock. For these reasons, the procedure outlined in Section 7.13 of the HEC-18 manual "Pier Scour in Erodible Rock" was referenced to evaluate changes to scour potential at this bridge. This is similar to the procedure performed by AECOM (for MDOT) to evaluate bridge scour prior to the recent I-196 bridge pier extension project completed in 2020 (MDOT, 2016).

This process evaluates the potential for bedrock to erode by comparing the stream power of the approach flow to the critical stream power necessary to initiate scour, which is a function of bedrock properties. Peak stream power is a function of discharge and energy loss at the location of scour. Stream power for this evaluation was calculated using Equation 7.39 from the HEC-18 manual:

Equation 7.39:

$$P_a = 7.853\ \rho\ (\tau\ /\rho\ )^{3/2}$$

where: P_a = Stream power of approach flow, W/m2 ; ρ = Mass density of water, 1000 kg/m3 ; τ = Bed shear stress of approach flow, N/m2 or Pa

Critical stream power at each bridge pier was calculated by AECOM, based on core samples near each pier, for the scour evaluation performed by MDOT in 2016. These values were used to compare calculated peak stream power against to evaluate potential of erodibility. The lowest critical stream power calculated by MDOT on the existing riverbed was 8,739 W/m^2; erodibility and factors of safety are evaluated herein against this value as a conservative assumption.

Critical stream power at all other bridge piers was more than twice as much as this minimum value (MDOT, 2016). The MDOT analysis used Equation 7.39 to calculate the stream power of the approach flow during the 100-yr flood and compared it against the critical stream power to make a determination on the erodibility and scour potential at the bridge piers.

Modeling results for the Project indicate that the proposed changes of the project would increase scour potential at I-196 for flow rates up to approximately 13,000 cfs and generally matching existing conditions flow rates above 13,000 cfs. For this reason, the scour evaluation performed for I-196 considered flows as low as the annual average flow of 3,900 cfs. Two-dimensional hydraulic modeling results were referenced to determine what flow rate produced peak stream power at the location of the I-196 bridge crossing under existing and post-project conditions.

Equation 7.39 increases with increasing calculated bed shear stresses; therefore, the maximum calculated bed shear stress from the SRH-2D models were entered into the equation for each flow rate evaluated. The resulting calculated stream power for each flow rate is presented in Table 5. For existing conditions, flow rates above 13,000 cfs backwater the I-196 location and reduce calculated bed shear stresses, resulting in peak stream power occurring at 13,000 cfs. Under post-project conditions, modeling results indicate that

peak bed shear stress (and therefore, calculated stream power) would occur at approximately 7,500 cfs and increases in stream power compared to existing conditions were calculated for flow rates up to 13,000 cfs. However, maximum calculated stream power remained well below the minimum calculated critical stream power determined by MDOT, resulting in minimum factors of safety against bedrock scour of 64 and confirming the conclusions of the MDOT scour evaluation (MDOT, 2016).

Table 5: Stream Power Evaluation, using Equation 7.39 of HEC-18 Manual

Flow Rate (cfs)	Existing Conditions		Proposed Conditions	
	Stream Power (W/m2)	Factor of Safety Against Scour(1)	Stream Power (W/m2)	Factor of Safety Against Scour*
3,900	20.8	420	122 (2)	72
5,000	26.5	330	126 (2)	69
7,500	39.2	223	136 (2)	64
10,000	50.3	174	123 (2)	71
13,000	55.6	157	70.2	124
18,000	35.4	247	35.4	247
26,000	30.9	283	30.9	283
31,000	37.3	234	30.0	292

(1) Minimum critical stream power calculated by MDOT (8660.1 W/m^2) divided by calculated stream power.

(2) Modeled areas of super-critical flow.

5.2 TEMPORARY CONSTRUCTION CONDITIONS SCOUR

The Recommended Construction Sequencing Report provides details for construction strategies and sequencing (RiverRestoration, 2024) and recommended construction access and care of water plan is included in the "T Sheets" of the design drawings. All in-river construction work is expected to be performed during flow rates of less than approximately 3,900 cfs; construction activities would stop, and all personnel and equipment removed from the river during flow rates greater than approximately 4,000 cfs. Limiting construction to lower flows allows construction activities to occur in the wet, reducing the need for expansive work isolation areas, but also allowing flow conditions to influence construction schedule to a larger degree.

Causeways of imported clean coarse aggregate would be installed along the west bank to access the Dam 1, 3, and 4 construction areas, as well as areas downstream of Pearl Street. The Dam 2 construction area would be accessed directly from the staging area in Ah-Nab-Awen Park and would be isolated by a cofferdam on the west side of the river.

Temporary construction conditions will have two general configurations; the first being with the work at the west side of Dam 2 isolated with a cofferdam and the second being after the cofferdam has been

removed. Both conditions have been evaluated for potential impacts to bridge scour using the same process used to evaluate post-project conditions.

Similar to the evaluation of post-project conditions, results of one-dimensional modeling indicate that relative differences between maximum scour potential are on the order of modeling accuracy. Peak scour depths were calculated at the 500-yr flood across all locations and maximum scour differences during any flow rate were less than 0.5% for temporary construction conditions, indicating minimal effects to large flow events, which are typically the largest scour-producing flows. The first condition, with Dam 2 isolation in place is compared in Table 6 and second temporary condition, after isolation has been removed, is compared in Table 7.

Table 6: Calculated temporary construction conditions scour depths with Dam 2 isolation in place and percent increase compared to existing conditions

Fulton Street	14.5 (0%)	16 (0%)	16.8 (0%)	17.6 (0%)	18.2 (0%)	18.8 (0%)	20 (0%)

5.2.1 EFFECTS OF TWO-DIMENSIONAL HYDRAULICS DURING TEMPORARY ISOLATED CONDITIONS

During the isolation of the west side of the channel at the Dam 2 location, the hydraulics of the river will be influenced by the presence of the cofferdam. For this reason, SRH-2D modeling results have been evaluated at a range of lower flow rates to determine level of risk of increased scour potential during construction, specifically Gillett Bridge, immediately downstream of the isolation area.

To maximize the efficiency of work within the isolation system, which would be overtopped during flow rates greater than approximately 4,000 cfs, the isolated work would be done during July and August, when minimum annual flow rates have historically been recorded in the project area. Performing isolated work during this low flow period would also minimize potential for increased scour potential at the bridge piers of Gillett pedestrian bridge, directly downstream of the isolated work area.

Through construction sequencing and planning, the project has minimized the potential for increased scour potential at bridges within the project area. However, based on historic gaged flow data, there will still be a small probability, based on historic gage data, that some of the bridge piers of Gillett Bridge may experience increased scour potential, resulting in calculated scour depths similar to those calculated for the 100-yr flood under existing conditions. Although this probability is very low, and has been minimized through construction sequencing, the City and the design engineer have agreed that temporary scour protection should be installed at the three eastern bridge piers prior to work isolation.

6. DISCUSSION AND RECOMMENDATIONS

The following discussion and recommendations assume that all bridge piers within the project area are currently maintained with adequate scour protection to withstand the 100-yr flood event. It is recommended that all bridge piers be inspected by the owner and contractor to verify the assumption that they have been maintained to withstand hydraulics associated with the 100-yr flood event.

The bridge scour evaluation presented here concludes that, based on the comparison of existing condition hydraulics to proposed condition hydraulics within the project reach (Fulton Street to Bridge Street), permanent scour protection is not required as a result of the project. Relative differences between maximum scour potential are on the order of modeling accuracy.

Because the project lowers the grade control downstream of I-196, more scour potential is expected at the I-196 Bridge piers at flow rates up to 13,000 cfs. Conservative modeling assumptions indicate potential for super-critical flows and hydraulic jumps to occur in areas beneath the bridge. Conservative stream power calculation assumptions show that maximum calculated stream power remains below critical stream power determined by MDOT (MDOT, 2016) with minimum factors of safety of 2.0. The evaluation at I-196 concludes that, based on the findings and conclusions of the MDOT scour evaluation in 2016, potential increases in stream power beneath I-196 may result from the project; however calculated increases remain below critical stream power to induce scour beneath the bridge. MDOT has reviewed this report, and the project team has discussed the I-196 scour evaluations with them. Through this coordination, MDOT confirmed they have no further questions or concerns with the scour analysis methodology at I-196 (MDOT, personal communication, June 3, 2024). The City will continue to work with MDOT to address any future concerns on the hydraulics.

HEC-RAS 1-D evaluations of temporary construction conditions show that any increases in calculated pier scour depths remain within the modeling accuracy and would maintain a Factor of Safety against scour.

However, SRH-2D evaluations during work isolation highlight potential risk of increased scour potential at Gillett Bridge. Work isolation at the Dam 2 location has been sequenced to occur during the historically low flow period of July/August, when there are minimal probabilities of flows exceeding maximum scour-inducing flows. Although low, there will remain a risk that these flows occur while the isolation system is in place. Therefore, temporary scour protection has been recommended for the eastern three bridge piers of Gillett Bridge. The temporary scour protection included in the recommended care of water plan is for either 9" D_{50} riprap or grout-filled bags per HEC-23 standards. The total footprint of temporary scour protection would be 2x pier width (14.4 ft) around each pier, per design guidelines. Scour protection would be removed prior to completion of the project. Access to install and remove the temporary scour protection would be provided from the causeway along the west bank of the river, either by tracking directly on the riverbed or a low causeway, if necessary to reduce flow depths. Refer to the T Sheets of TOC No. 3 Design Drawings for more details on these recommendations.

7. SUMMARY

Analysis of the hydraulic influence on bridge scour was performed for existing and proposed conditions of the Grand River at Grand Rapids, MI. Hydraulic modeling and data analysis using the standard engineering guidelines of HEC-18 indicate that proposed project actions will minimally affect the largest scour producing flows (100-yr and 500-yr return flood, differences ~ 0.5% or less).

Increased scour potential is anticipated during lower flow rates (up to 13,000 cfs) at I-196; however, is not expected to erode the primarily bedrock streambed.

Two-dimensional modeling of temporary conditions highlighted the (low probability) of bridge scour concerns at Gillett Bridge during work isolation at the Dam 2 location. Temporary scour protection has been recommended.

May 2024

This document entitled Operation, Maintenance, Repair, Rehabilitation, and Replacement report: Grand River Revitalization Project, Grand Rapids, Michigan was prepared by RiverRestoration.org, LLC for the account of City of Grand Rapids (Client). The material in it reflects the professional judgement of RiverRestoration in light of the scope, schedule, and other limitations stated in the document and in contract between RiverRestoration and Client.

Approved by
Scott Prins, P.E.

1.0 Introduction

River projects may be subjected to fluvial, sediment transport, ice and other environmental forces that may impact the function of a built project and require action. However, the dynamic nature of a river may also be allowed for in design and some changes to the built project under the environmental forces may not require action. Operation, maintenance, repair, rehabilitation, and replacement (OMRR&R) efforts are forecasted to restore a project to as-built conditions when action is deemed necessary.

For the Grand Rapids Revitalization Project, the proposed grading is anticipated to adjust to post-construction hydraulics and some localized scour and deposition may result, along with slight shifts in boulder and riprap. Changes that may require action include those that threaten public safety or infrastructure. Public safety may include flood threats, bank access, or adverse hydraulics for water-based recreation. Excessive scour may threaten bridges, floodwalls, utilities or the banks of river front properties.

The design of River Restoration projects seeks to emphasize minimal long-term OMRR&R. Development of OMRR&R cost estimates account for expected upkeep of project features for as long as the project exists. For this project, a 50-year lifetime was assumed. The objective of OMRR&R procedures is to maintain structures or project features to "as-built" conditions, or conditions that provide for acceptable project performance consistent with project objectives.

- **Operation** includes regular monitoring, inspections, data collection and reporting. These procedures should be conducted regularly to evaluate design goals and constraints throughout the life of the project. A maximum interval of 5 years is recommended for operational procedures. Operational procedures are recommended to be performed during and after larger floods, significant droughts, ice jams, and other processes outside of average annual hydrologic events.
- **Maintenance** is for routine, planned and scheduled upkeep of project features, equipment, or supplies necessary to maintain proper functionality of project elements. Maintenance is not anticipated to be required for the design elements of the Project.
- **Repair** is for unscheduled correction resulting from unforeseen circumstances that are outside of the design assumptions for the project. These include but are not limited to environmental events and vandalism.
- **Rehabilitation** is to correct un-anticipated hydraulics, shifting, wear and tear, weathering, or materials degradation to improve project performance. Rehabilitation includes resetting features, augmenting features with additional materials, or refurbishing of features or components.
- **Replacement** includes the removal, demolition and disposal, and replacement of project features or components that cannot be repaired or rehabilitated.

In-stream OMRR&R may require design permitting, temporary access to the channel, and temporary care of water.

Table 1 OMRR&R Schedule for elements of the Grand River Revitalization Project

ELEMENT	Operation	Maintenance	Repair	Rehabilitate	Replace
	Years	Years	Years	Years	Years
Boulder Arch Structures	5	N	15	50	N
Riprap Substructures	5	N	15	50	N
Constructed Riffles with Emergent Boulders	5	N	15	50	N
Bank Vane Structures	5	N	15	50	N
Scattered Habitat Boulders	5	N	15	50	N

2.0 Grade Control Structures

Boulder and riprap structures have been designed to provide grade control throughout the project reach. These structures are expected to adjust and settle in the fluvial environment and minor fluvial adjustment is considered beneficial to the success of the project; however, major shifts in structures that cause adverse effects such as loss of hydraulic control, erosion, bridge scour or adverse hydraulics may periodically need to be addressed. Grade control structures are expected to have OMRR&R costs associated with potential repair and rehabilitation, which may include resetting boulders with large machinery accessing the damage site by tracking on the riverbed or augmenting structures with additional imported material delivered by tracked equipment or barges when hydraulic conditions allow barge access. Costs may be concentrated in a single year, especially if a major flow or ice event impacts multiple structures. The structures are designed to be functional in a fail-safe mode until the repair or rehabilitation can be scheduled, likely in a low water season. Temporary spikes in turbidity may occur during riverbed disturbances associated with these activities.

2.1 Boulder Arch Structures

Boulder arch structures will be constructed by placing boulder into a tightly stacked boulder matrix. The boulder matrix includes stable fill in void spaces. Structures are designed to resist overturning and sliding; however, minor movement may be expected due to changes in morphology, scour or deposition. Potential repairs may be required to remove debris, or to reset material that has been impacted by debris, ice or significant erosion. Rehabilitation is expected to consist of resetting or augmenting the proposed features to achieve desired hydraulic performance throughout the life of the project. Additional material may augment the matrix where necessary to re-establish finished grade or refill and stabilize voids. Work would require access by a large track vehicle on the bed of the river channel and access from the shoreline and resetting of boulders or augmentation of additional boulder matrix material in the wet and possibly flowing water.

2.2 Riffle Feature Substructures

Riffle Feature Substructures are designed to maintain stable grade control for the project reach by controlling upstream water surface elevations and distributing hydraulic gradient throughout the reach. Structures are designed to resist overturning and sliding; however, minor movement may be expected due

to changes in morphology, scour or deposition. Changes in grade control may impact hydraulics, sediment transport, fish passage and other design features in an adverse way. Boulders are recommended for Riffle Feature Substructures and would have the least associated OMRR&R; however, Substructures may be constructed out of riprap or alluvium per owner's preference with relative increased OMRR&R respectively. Potential repairs may be required to remove debris, reset material that has been impacted by debris or ice, or augment structure in response to inconsistencies between post-project conditions and design assumptions. Rehabilitation is expected to consist of resetting or augmenting the proposed features to maintain proper hydraulic performance throughout the life of the project. Additional material may be replaced where necessary to re-establish finished grade. Work would require access by a large track vehicle on the bed of the river channel and access from the shoreline and resetting of riprap or augmentation of additional material in the wet and possibly flowing water.

3.0 Bridge Scour Protection

Bridges in the project reach may be subject to slightly different scour conditions than the existing conditions. Current bridge scour inspection and maintenance schedules should continue and be added one year after work is performed and again after any major flood or ice event. The rehabilitation of post project scour protection is not anticipated to be different than the current procedures and no additional cost is assumed herein. Any flow patterns that are directed at pier fronts and creating a scour concern should be reconfigured and adjusted to flow though the openings without a significant angle of attack on the piers. This may require tracked equipment to access the river and excavate or augment boulder structures in the wet and flowing river. This may result in temporary increases in downstream turbidity.

4.0 Alluvial Riffle Structures

The imported alluvium that will comprise riffle structures has been designed to remain locally stable with a factor of safety of 2 based on modeled bed shear stresses and particle size incipient motion evaluations. The finished grade of the project is expected to morph with the fluvial environment and locally scour and deposit until a stable equilibrium is established.

4.1 Local Deposition and Scour

Local deposition and scour of alluvial material in Riffle Structures will likely occur and a dynamic equilibrium between scouring hydraulics and the new riverbed would be established. Local deposition or scour is not anticipated to require maintenance; however, if unforeseen events occur or the level of local scour is determined unsafe in any location, heavy equipment may have to access the river channel to restore desired grades with stable material. This work may require track equipment to drive on the riverbed in the wet channel and access from the shoreline.

4.2 Debris Removal

Deposits of large woody debris and other debris occur in the existing channel and are likely to also occur under post-project conditions. There is a relatively higher likelihood of debris becoming hung up on the Alluvial Riffle Structures due to relatively larger area and shallower flow depths compared to other parts of the channel. Repairs may be required on a case-by-case bases to address any debris that becomes hung up. Repairs may require removal from the river channel similar to existing conditions. Removal of woody debris will likely be a combination of chain sawing the debris in place (likely within the flowing water) and allowing the smaller logs to float downstream. In some cases, heavy equipment may have to access the river channel to remove large logs or other major debris. This work may require track equipment to drive on the riverbed in the wet channel and access from the shoreline.

4.3 Aggregation of Substrate Near Fulton Street

The reach break near Fulton Street has the potential to aggrade gravel bars that would be unable to transport into the reach downstream of US-131. The project is designed to minimize and avoid this potential aggregation through stable sizing of substrate; however, monitoring of gravel deposits near Fulton Street is still recommended. A deposit that requires action would be one that impacts flood risk. A deposit substantial enough to impact flood risk has been modeled to be extremely unlikely. However, if a significant deposition of substrate does form, survey and engineering services would be required to determine if an increased flood hazard is developing. If determined necessary, the materials would be accessed by heavy equipment tracking on the bed of the river and removing the deposit to be hauled offsite and disposed in an upland area.

4.4 Ice Jamming

Ice jamming is not anticipated to be significantly different than the existing conditions. Ice jamming problems are anticipated to be concentrated downstream of Fulton Street the same as existing conditions. However, as a precaution ice formation and jamming should be monitored and may require maintenance similar to existing conditions, such as mechanically removing (or in emergencies with blasting) of jams and problem ice formations.

All individual substrate particles, including boulders may shift and adjust locally. The collapse of an ice jam can deposit significant weight of ice on a riverbed during a rapid drawdown. This is impossible to predict, not cost effective to design for, currently occurs under existing conditions, was noted in 2005 by anglers that had mapped the riverbed, and is only a temporary local phenomenon and not a continual process that forms downstream bars. Ice damage would be evaluated after an event and require repair if resulting in hydraulic hazards or degradations.

Table of Contents

Section 1 – Introduction..... 3

Section 2 – Construction Areas and Sequencing 3

Section 3 – Description of Construction Activities..... 4

Section 1 – Introduction

The following construction sequencing has been developed through coordination with the construction management adviser for the City and regulatory agencies as the most feasible means for construction that also minimizes direct impacts to the existing channel.

All in-river construction work is expected to be performed during flow rates of less than approximately 3,900 cfs. Limiting construction to lower flows allows construction activities to occur in the wet, reducing the need for expansive work isolation areas. Causeways of imported clean coarse aggregate would be installed along the west bank to access the Dam 1, 3, and 4 construction areas, as well as areas downstream of Pearl Street. The Dam 2 construction area would be accessed directly from the staging area and would be isolated by a cofferdam on the west side. Refer to Figure 1 (attached) for the layout of temporary construction access and construction areas. Refer to Section 3 and the construction design drawings for the proposed improvements at each construction area.

Section 2 – Construction Areas and Sequencing

Construction sequencing has been separated into four categories. These categories would generally follow each other sequentially; however, concurrent work between categories has been described where applicable.

Category 1: Mobilization (~8 weeks)

- All work would be outside the river and completed prior to commencing in-river work or July 1st, whichever come later.
- Work includes establishing staging areas, installing BMPS and contractor facilities, and importing and stockpiling materials

Category 2: Preparatory Work in River (~6 weeks)

- Installation of access causeway to each work area (refer to Figure 1)
- Install temporary scour protection at Gillett Bridge
- Installation of in-river BMPs

Category 3: Initial In-river Construction (~10 weeks)

- Begins with installation of work isolation (aggregate bag cofferdam) at the Dam 2 Construction Area.
- Extends through the completion of the (isolated) west side of the Dam 2 Construction Area
- Concurrent work activities may include:
    - Any category 2 work downstream of Dam 2 which has not yet been completed.
    - Fish and mussel relocation activities within isolated area
    - Construction of any proposed improvements downstream of Dam 2

Category 4: Final In-river Construction (~9 weeks)

- Begins with the removal of work isolation (aggregate bag cofferdam) at the Dam 2 Construction Area.
    - Dam 4 to be removed immediately after Dam 2 construction is complete.
- Extends through completion of all proposed improvements and removal of all temporary access causeways
- Concurrent work activities may include:
    - Extension of upstream causeway at Dam 2 Construction Area to 593' elevation.
    - Category 2 work for Dams 3 and 4 Construction location after completion of Dam 2 upstream causeway to 593' elevation.
    - Removal of Dam 3 and installation of proposed improvements at Dam 3
    - Completion of east side of Dam 2 Construction (i.e. full completion of proposed improvements at Dam 2 Construction Area)
    - Removal of Dam 4 and installation of proposed improvements at Dam 4 after the full completion of proposed improvements at Dam 2.
    - Completion of all proposed improvements downstream of Dam 2
    - Inspection of hydraulic performance of completed improvements
    - Removal of all temporary construction access causeways and in-river BMPs

Section 3 – Description of Construction Activities

Dam 2 Construction Area

Within the work isolation area, Dam 2 would be removed, and the west half of the proposed diversified hydraulic structure would be constructed. The cofferdam would remain in the river until construction within it is complete; all equipment and personnel would be removed from the channel and the site flooded prior to flow events greater than approximately 3,900 cfs.

Once the west side is complete, the cofferdams would be removed and the proposed improvements on the east side would be constructed, using previously installed causeways to access. On the east side of the river, Dam 2 would be demolished and removed, and the proposed riffle structure would be constructed. The cofferdams and causeways would be removed following the completion of Dam 2 feature construction.

Dam 1 Construction Area

The low-head dam would be demolished and removed, and the proposed riffle structure would be constructed. Temporary causeways upstream and downstream of the constructed riffle would be removed following construction.

Dams 3 and 4 Construction Area

Installation of the access causeway and construction of proposed improvements to Dam 3, including the removal of the dam, would not occur until the cofferdam within the Dam 2 construction area is removed and the contractor is confident the Dam 2 feature will be completed within the same construction season. The installation of the access causeway and the removal of Dam 4 would not occur until the Dam 2 feature has been fully constructed.

Causeways to, and along, Dams 3 and 4 would be installed and the dams demolished and removed. The channel upstream of the dams would be regraded per plans. Emergent habitat boulders would also be placed within the Dam 3 removal and regraded area. Temporary causeways would be removed following construction.

Dams Removal Means and Methods

- Other than the western half of Dam 2, all dam removal would be performed under un-isolated conditions.
- Operating from established causeways and working from east to west, 20-30 ft long sections would be removed at one time.
- The upstream face of the dam would be exposed by temporarily moving the causeway material at the face of the dam to the other side of the causeway while work is performed.
- Excavate to bottom of concrete on upstream side of 20-30 ft section of dam.
- Use a hydraulic concrete breaker with compressed air unit, mounted on an excavator, to break concrete into 24-48” pieces.
- Load the broken concrete into articulated off-road dump trucks and relocate the concrete to the park staging area.
- Load the concrete into OTR dump trucks and haul to disposal site
- Contractor will visually monitor turbidity and adjust water quality control BMPs as needed.

Construction Areas downstream of Pearl St.

Two emergent habitat boulder fields and a series of bank vane structures would be constructed between Pearl and Fulton Streets. Both areas would be accessed from a causeway extending from Ah-Nab-Awen Park to the construction areas. Emergent habitat boulders on the west side would be placed from the causeway, while boulders on the east half of the river would be placed while tracking in the river. Boulder vanes would be constructed upstream and downstream of Grand Rapids Public Museum Carousel and on the east bank near the JW Marriot Hotel. Between Blue and Fulton Street, a diversified boulder arch structure would be constructed on the west side of the river and emergent habitat boulder field on the east side.

Following completion of all proposed improvements and final inspection, all temporary causeways, construction equipment, and BMPs would be removed from the river.

Appendix B. The project area with depth and depth-averaged velocity at 2500, 3900, 5000 and 7500 cfs.

Appendix C. Depth and velocity heatmaps of project area during difficult hydraulic conditions depicting 15 swimpaths. Figures display the depth, velocity and percent of swimming distance expended for a fish traveling along each of the swimpaths.

ACKNOWLEDGEMENTS

This Fish Passage Assessment was completed under contract to Grand Rapids Whitewater (GRWW) as part of the efforts to restore and revitalize the Grand River in Grand Rapids. Mr. Matt Chapman (GRWW), Mr. Michael Staal (City of Grand Rapids [CGR]), and Mr. Scott Prins (River Restoration [RRO]) provided project details. Mr. Patrick Ertel, Dr. Tammy Newcomb, Mr. Jay Wesley (Michigan Department of Natural Resources [MDNR]), and Luke Trumble and Amy Lounds (Michigan Department of Environment, Great Lakes, and Energy [EGLE]) provided advice throughout the informal consultation process. Dr. Ted Castro-Santos (United States Geological Survey), Ms. Susan Wells (United States Fish and Wildlife Service), and Dr. Robert McLaughlin (Michigan State University) provided critique of the fish passage analysis methodology.

1.0 INTRODUCTION

The City of Grand Rapids is pursuing to improve aquatic habitat in the Lower Grand River where it flows through downtown Grand Rapids, Kent County, Michigan (GVMC, 2011). Goals of the project include developing a river design that is aesthetically and functionally natural as possible, within the constraints of a large urban river, and to achieve fish passage and aquatic habitat enhancement targets as determined by the Michigan Department of Natural Resources (MDNR) and the project team. The lower reach of the Grand River Revitalization project is located on the Grand River mainstem in the City of Grand Rapids, Michigan from approximately 40 meters (131 ft) upstream of Bridge Street to Fulton Street (Figure 1-1).

1.1 Purpose of the Document

The purpose of the fish passage report is to review the design plans for the Grand River Revitalization project and evaluate the passage of desirable fish species in the lower reach project area. A fish passage report was previously submitted in 2020 (ESC 2020), for a permit application that was withdrawn in March 2023. Following the withdrawal, a new design (proposed design) was developed during focused and frequent consultation between Grand Rapids WhiteWater (GRWW), the City of Grand Rapids (CGR), Michigan Department of Environment, Great Lakes and Energy (EGLE) and MDNR. One of the primary objectives for the proposed design was to maximize fish passage and aquatic habitat while minimizing impacts. This evaluation report focuses on the proposed design where habitat elements were removed while others were added.

1.2 Proposed Action

The stated purpose of revitalizing the rapids in Grand Rapids is described in the Biological Assessment (Dunn 2024) as, "To restore the rapids, improve public safety, restore aquatic habitat diversity and suitability for native Great lakes fish and mussel species, and enhance river access and use." This action includes removing the four low head dams which are barriers to several species of fish, and to construct habitat features known to successfully pass fish. The proposed features of the action include riffles, boulder drop structures, bank vane structures,

and emergent habitat boulders that are found in many nature-like fishway designs and the historic condition of the rapids. In fall of 2023, the design was modified to avoid and minimize impacts to freshwater mussel and fish species. Appendix A (modified from Dunn 2024) shows the current design that was coordinated with EGLE and MDNR and evaluated in this report. The current design has reduced the construction and permanent impacts from the previous while incorporating elements that have successfully been used to pass fish in Michigan. Changes that were incorporated into the current design are described as follows (Dunn 2024):

Between Blue Bridge and Fulton Street

- The boulder wave structure on the west side of the channel was replaced with an augmented boulder vane structure with a reduced footprint and surrounding scattered boulders.
- The previous design included a recovery pool downstream of the wave that has been removed from the design. A small scour pool is included directly downstream of the vane structure, similar to other Michigan projects that have implemented weir or Aadland (2010) rock arch designs.

Between Pearl and Blue Bridge

- The hydraulic feature in this area, which included a boulder wave structure on the west connected to a constructed riffle structure on the east, has been replaced with scattered boulder and a series of bank vane structures to provide slack water near designated access points on the bank.
- The recovery pool of the previous design has been removed.

Between Gillett and Pearl Street (Location of Dam 1)

- The hydraulic feature at Dam 1, which included a boulder wave structure on the west side connected to a constructed riffle structure on the east, has been replaced with a single constructed riffle with emergent habitat boulders and moved downstream to have more overlap with the Dam 1 removal footprint.
- The recovery pool of the previous design has been removed.

Between Bridge St and Gillet (Location of Dam 2)

- The hydraulic feature at Dam 2, which included a boulder wave structure on the west connected to a constructed riffle structure on the east, has been replaced with a hydraulic feature that combines constructed riffles on either side of the river with a series of boulder drop structures in the center of the channel. The new hydraulic feature has a reduced footprint.
- The recovery pool of the previous design has been removed. Small scour pools are included directly downstream of the boulder drop structures, similar to other Michigan projects that have implemented W-weir or Aadland rock arch designs.

Between Bridge St and Gillet (Location of dam 3)

- The dam removal limits have been expanded, based on coordination with EGLE, to include a re-grading of the channel upstream of Dam 3
- Scattered habitat boulders are proposed to be placed within the dam removal footprint.

Location of Dam 4

- The dam removal limits have been expanded, based on coordination with EGLE, to include re-grading of the channel upstream of Dam 4.

2.0 AFFECTED ENVIRONMENT AND BIOLOGICAL RESOURCES

2.1 Lower Grand River Fishery

The project area provides an important and diverse recreational fishery for resident fish species including walleye (*Sander vitreus*), sucker spp., channel catfish (*Ictalurus punctatus*) and smallmouth bass (*Micropterus dolomieu*). Seasonal opportunities exist for migrating fish and include walleye and steelhead (*Oncorynchus mykiss*) in the Spring, and Chinook salmon (*Oncorynchus tshawytscha*) in the Fall. Maintaining, and maximizing, these fishing opportunities is important to all partners involved in the revitalization project. The fish community in the project area is highly diverse, includes many tolerant species, and has changed from its historic condition because of the reduction in rapid and riffle habitat. Many of the fish species in the project area are ubiquitous throughout the mainstem and not associated with swift water habitats. For an extensive review of the Grand River fishery see Hanshue and Harrington (2017).

Two State Threatened fish species are found in the project area. There is a small lake sturgeon (*Acipencer fulvescens*) population that persists in the project area and is only suspected to spawn near Plaster Creek (~1.25 mi. downstream of Fulton Street) and in the project area downstream of 6th Street dam. The Grand River population has been placed into the 'small declining' category based on a low suspected adult population size and declining population trajectory (Hayes and Caroffino 2012). The 6th Street dam is a barrier to historic spawning grounds of lake sturgeon (Hanshue and Harrington 2017) and incidental catch by fisherman occurs each spring. Lake sturgeon recruitment has been documented during two years of a five-year study that has occurred below the project area by a locally-based team of researchers during fall assessments (Grand Rapids Public Museum 2024). The river redhorse (*Moxostoma carinatum*) is a large-bodied sucker species found in the Grand River. There have been recent obseravations in the project area during their spring spawning period (S. Hanshue, MDNR personal communication).

3.0 FISH PASSAGE EVALUATION CONSIDERATIONS

The following sections describe criteria that were developed for the fish passage evaluation, the areas where analysis occurred, methods used for hydraulic model development, and details of fish passage evaluation procedures and results.

3.1.1 General Considerations

The proposed design uses design and construction criteria, that when achieved, will improve fish passage conditions in the Grand River for the diverse fish community. The proposed action includes rock arch rapids, boulder clusters, and small hooks which are design aspects found in nature-like fishways (Aadland 2010). Nature-like design principles have been published by many sources including MDNR, Aadland (2010), Newbury (2013, 2010) and have been successful in meeting fish passage objectives. Fundamental to the design of nature-like fishways is that they pass a broad range of species, emulate habitats found in natural systems, are resilient to a range of flows, and are stable through extreme conditions.

During consultation with MDNR specific design targets were developed and consistent with nature-like fishways, that if met, would result in environmental conditions that are within the swimming abilities of desirable fish species and should accommodate passage of the broader fish community. Specific design targets included and met in the proposed action:

- **Headloss per weir of ≤0.24 m (0.8 ft):** The proposed design, when not submerged by tailwater, would have a maximum headloss of 0.61 m (2 ft) with an average headloss of ~0.54 m (~1.8 ft). The dam 1 riffle starts to see reduced headloss of tailwater levels around 5000 cfs and the dam 2 feature around 7,500-10,000k cfs.
- **Boulder weir gap width between 0.15 – 91 m (0.5 – 3 ft):** Gaps between raised boulders on the crest of the boulder drops have a minimum spacing of 0.61 m (2 ft) with a maximum of 3.66 to 4.57 m (12 to 15 ft) where flow paths are desirable for boat passage.
- **Mild downslopes at riffles:** Constructed riffles have a target slope of 50:1 and the grading will not be steeper than ~45:1 over the riffles.
- **Center depth in deep pools at ≥1.68 m (5.5 ft):** Maximum pools depths are designed at 2.1 m (7 ft) while active and not submerged with an average depth (3,900 cfs) of 1.68 m (5.5 ft).
- **Minimum pool depth of 0.91 m (3 ft):** Minimum pools depths are designed at 1.07 m (3.5 ft).

The fish passage analysis provides a quantitative tool to assess if the design will meet fish passage objectives. Two species were identified as indicator species to use in the analysis because they are both important members of the native fish community, have considerable public interest, and represent different fish swimming groups and swimming performance abilities. For instance, the river redhorse has the same fatigue equation to walleye in the model used for analysis. This allows for evaluating walleye passage along with river redhorse and a suite of other species in the model. The decision was made to evaluate the two species during a range of hydraulic conditions and design features (riffles, weir features, etc.). **Important to this analysis is that fish passage was evaluated at the more extreme modeled conditions** assuming that if passage was achieved at locations and conditions of "worst case scenario" that passage would also be achieved at other locations with less challenging hydraulic conditions.

3.1.2 Fish Groupings Considered in Passage Evaluation

Walleye and lake sturgeon were the target fish species selected based upon a series of criteria, including 1) consultation with management agencies, 2) conservation status, 3) availability of peer-reviewed, locally applicable habitat use and swimming capabilities, and 4) known movement and/or migratory behavior.

3.1.3 Hydraulic Modelling

For modelling of flow velocity and flow depth, SRH-2D models were used. Calculations were based upon depth-averaged velocity and near-bottom velocity. SRH-2D solves two-dimensional dynamic wave equations to resolve depth-averaged hydraulics for a variety of scales and applications. The software has been widely implemented and validated. Applied to the Grand River, the model resolves hydraulic parameters (e.g. depth, velocity at a resolution of 0.15 m (0.5 ft) across the spatial domain of the river system.

Hydraulic conditions used in evaluation:
2,500 CFS: 75% exceeded average daily flow rate and a common summertime flow
3,900 CFS: 50% exceeded average daily flow rate
5,000 CFS: Near 25% exceeded average daily flow rate and within range of spring spawning flow
7,000 CFS: Near 10% exceeded average daily flow rate and mid- to higher range of spring spawning flow

The flows were selected in consultation with MDNR to account for temporal and environmental variability and to represent expected seasonal conditions encountered in the Grand River. Hydraulic model outputs for the project reach at the four evaluated discharges are presented in Appendix B.

3.1.4 Velocity

Two velocity values were computed; 1) depth-averaged velocity, and 2) near-bed velocity. Both velocity estimators have advantages and limitations but together provide utility for evaluating fish passage. Depth-averaged velocity is widely used for evaluating fish passage and assessing whether current velocity would pose a burst or exhaustive swim barrier. Its use here seems appropriate to characterize the variable local hydraulic conditions (i.e. velocity and depth), found across the project river channel. In some cases, near-bed velocity will also be presented using methodology developed by Vacher (2005) and with spreadsheets developed by EGLE and MDNR to calculate velocity at 80% depth using average velocity and average depth estimates. The velocity reduction in near-bed flows has been shown to provide significant benefit to fish when it is fully accessible (Jensen 2014). The use of near-bed velocity is only appropriate when a fish has adequate “headroom” or available depth to effectively use the reduced velocity near-bed layer. Therefore, near-bed velocity will be used in cases where adequate headroom exists and during times where average velocity may show a fish passage barrier. The average depth

calculations will be the primary velocity metric because it represents a more challenging passage scenario for fish than the near-bed velocity parameter.

3.1.5 Depth

Desired conditions for fish passage are maintained when deeper relative depths are available for a range of fish body sizes and life-stages. As body size increases for fish, so does the need for greater relative depths. Minimum depth design targets from comparable fish passage projects typically ranged from 0.23 to 0.31 m (0.75 to 1 ft) depth. The Little Rapids (Chippewa County, MI) project targeted a minimum of 0.31 m (1 ft) depth to accommodate spawning walleye (USDOC 2014) and the River Raisin (Monroe County, MI) project targeted minimum depths of ≥0.23 m (9 in) in the roughened boulder areas to accommodate walleye, lake sturgeon, and other target species (Cardno-JF New 2013). A minimum depth criterion of 0.31 m (1 ft) was suggested for spawning sturgeon by Threader et al. (1998). For this analysis the depth target was accordingly set at 0.31 m (1 ft) in the roughened boulder areas during springtime flows (approximately 5,000-7,500 cfs) to accommodate lake sturgeon movement during spawning.

4.0 ANALYSIS BACKGROUND

Prior to completing the fish passage analysis methodology, MDNR hosted a meeting with Encompass Socio-ecological Consulting (ESC), CGR and GRWW to discuss the methodology with a panel of fish passage experts from across North America. The purpose was to determine if the model was precautionary in its predictions and to gather recommendations for improvements. Following the meeting, the model was finalized, and data were analyzed using the procedure.

To evaluate the impact of the proposed design on fish passage, fifteen swimpaths were established across four reaches of the project area (Appendix C). Each swimpath was placed to begin downstream of a habitat feature and extend upstream until the hydraulic influence of the feature was passed. The project features were collaboratively evaluated by MDNR and ESC by reviewing heat maps across several discharges (2,500 – 7,500 cfs) with the intent of selecting difficult swimpath routes that were often the 'worst case scenario'. Accordingly, the difficult routes were assessed based on velocity and depth, and varied between site, channel feature and discharge. Locations were also selected to evaluate different types of channel features found in the project design. For example, in all project reaches are laterally positioned boulder clusters intended to provide conditions for successful fish passage and by evaluating one representative boulder cluster we could effectively extrapolate to other analogous features within the design.

The fifteen swimpaths were distributed across four project reaches in a downstream to upstream numbering (Appendix C):

Fulton Street to Blue Bridge: Swimpaths 11-15.

Analysis performed at 2,500 cfs because of relatively shallow depths and higher flow velocities. Evaluated features included boulder clusters, a mid-channel riffle, and nearshore riffles.

Grand Rapids Public Museum to Pearl Street: Swimpaths 7-10.

Analysis performed at 3,900 CFS because of relatively shallow depths and higher flow velocities on the rivers north side. Evaluated features included two small j-hooks and mid-channel/near-shore riffles.

Pearl Street to Gillett Bridge: Swimpaths 4-6.
Analysis performed at 5,000 cfs because of relatively shallow depths and higher velocities on the rivers west side. The 7,500 cfs condition was similar hydraulically but not selected because of deeper depths that would provide more headroom for fish to exploit near-bed velocities. Evaluated features included a mid-channel boulder cluster and riffles on the rivers west side.

Above Gillett Bridge: Swimpaths 1-3.
Analysis performed at 5,000 cfs because the conditions represent those during spawning migrations for walleye, salmon and sturgeon. The 7,500 cfs condition functioned similarly hydraulically but not selected because of deeper depths that would provide more headroom for fish to exploit near-bed velocities. Evaluated features included a modified W-weir with resting pool habitat, a mid-channel riffle, and a boulder cluster on the east side of the river.

To identify barriers to fish passage along swimpath routes an Excel model was developed (RiverRestoration and ESC) based on swimming performance curves from Katopodis and Gervais (2016). The code identified locations at which a fish shifted from passive to prolonged swimming mode based on stream velocity. Once the mode shift occurred a hydraulic barrier was identified, and an energetic function was applied that calculated the distance a fish was capable of swimming at prolonged or burst mode at a given velocity. Between each 0.5 m (1.64 ft) increment along the swim path the amount of energy expended, and a cumulative distance function calculated the percent of total distance remaining that a fish could travel. When the energy budget was expended over the hydraulic pathway, a complete barrier was identified.

To calculate the 0.5 m (1.64 ft) incremental distance, velocity/distance curves were fit using the fish swimming performance database "Icthyomechanics" from Katopodis and Gervais (2016) and validated these data with other relevant sources (Peake et al. 2011, Scruton et al. 1998, Castro-Santos 2005, Threader et al. 1998). The swimming performance variables used in the model included swimming speed (Body Lengths per Second) and time to fatigue statistics. The Ichthyomechanics database calculates swimming performance data by using taxonomic classifications to group fish species of similar swimming modes and swimming performances. Combining species into groups was found to improve the statistical analysis especially in cases of inadequate data and where inconsistent sampling methodologies occurred between studies. To evaluate walleye (and salmon) passage, distance curves were fit with total lengths of 0.38 m, 0.43 m and 0.51 m (15 in, 17 in, and 20 in) to be representative of spawning size fish. For the sturgeon group, two lengths were fit at 1.5 m and 1.86 m (60 in and 72 in). For each swimpath, the likelihood that 50% of a total length group would pass was used. The likelihood percentage was developed from the average distance a fish could travel at a velocity value and incorporated the

associated confidence bounds from Katopodis and Gervais (2016). The relationship between water velocity and estimated distance of travel for the walleye group and the sturgeon group is presented in Figure 4-1 for reference.

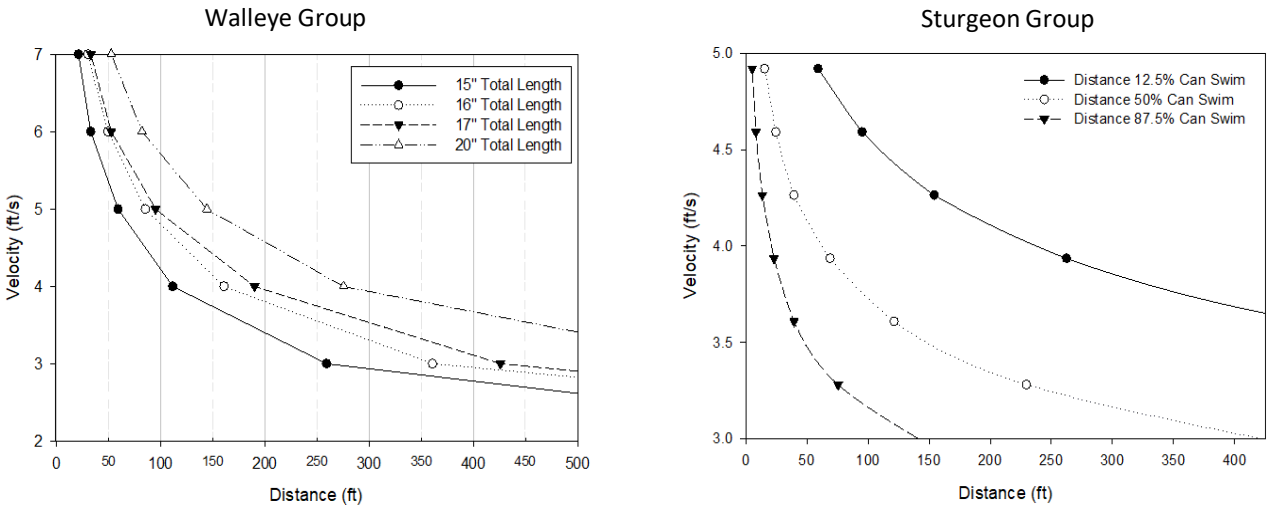

Figure 4-1. Relationship between water velocity (ft/s) and distance of travel (ft) for Salmon and Walleye group and Sturgeon.

5.0 RESULTS

5.1 Walleye Group Passage

A total of 15 swimpaths were analyzed using the model described above. Appendix C provides a depiction of each swimpath, velocity and depth values along the route, and a determination of passability based on the proportion of distance that a fish expended during upstream travel at 0.5 meter increments. Overall, the model predicted full passage at 10 of the 15 swimpaths for all three walleye length groups (Table 5-1).

Table 5-1. Estimated passage success for three length groups of walleye using average velocity at difficult swimpaths. A 'Y' designation indicates at least 50% of the population would pass.

			Total Length Groups		
Location	CFS	Swimpath #	0.38 m TL (15 in)	0.43 m TL (17 in)	0.51 m TL (20in)
Fulton Street to Blue Bridge	5,000	1	Y	Y	Y
		2	N	N	N
		3	Y	Y	Y
Grand Rapids Public Museum to Pearl Street	5,000	4	Y	Y	Y
		5	N	N	Y
		6	Y	Y	Y
Pearl Street to Gillet Bridge	3,900	7	Y	Y	Y
		8	N	N	Y
		9	Y	Y	Y
		10	Y	Y	Y
Fulton Street to Blue Bridge	2,500	11	N	N	Y
		12	N	N	N
		13	Y	Y	Y
		14	Y	Y	Y
		15	Y	Y	Y

The boulder cluster swimpaths (3, 6, and 14) were passable at each location for all walleye lengths. The backwater effect from the boulders, and decreased local flow where fish can rest, were discernable in the line graphs and showed a benefit to the modelled energy expended along the swimpaths. The depth along all swimpaths was >0.4 m except for Swimpath 6 when the path approached boulders, although deeper depths could be easily accessed by a fish if it's the path was altered slightly. Boulder clusters are a common design feature in each of the four reaches. Accordingly, passage of walleye and other similar species would be predicted to pass at each of the boulder cluster structures that were not analyzed.

Riffle feature swimpaths were placed at nine locations (Swimpaths 2, 4, 5, 8, 9, 11-13, 15) and at varying discharge conditions (Appendix C). Four of the eight swimpaths were estimated to have complete passage for all length groups of walleye, while two other swimpaths allowed passage of the largest length group. In Swimpath 2, a barrier to all length groups was due to a long travel distance at velocities near 1.5 m/s. For passage, fish would need to alter their route to exploit the lower sustained velocities near the riffle margins, use adjacent boulder areas, or exploit near-bed flows. In Swimpath 12, the barrier was largely produced by 2 m/s velocities at the crest of the weir structure, although fish could pass by accessing the margins of the crest where lower velocities exist. Even during low-flow conditions (2,500 cfs) the swimpaths maintained depths >0.4 m and would allow for fish to exploit reduced velocity near-bed flows.
Two swimpaths (7, 10) were positioned at near shore (margin) areas and used to evaluate small, j-hook structures in the design. The features are adjacent to the Grand Rapids Public Museum and just below the JW Marriott hotel. Both features produced conditions to pass walleye from all length groups. Below the proposed j-hook adjacent to the Grand Rapids Public Museum is a similar structure 83 m downstream where passage would also be expected.

A unique feature of the design is a modified W-weir (rock arch) design located between boulder clusters and constructed riffle features above the Gillett Bridge. Swimpath 1 was routed through the W-weir at the highest velocity and shallowest depth and passed over three-grade structures and three pools. The feature was passable for all length groups evaluated with a maximum of ≤50% energy reserves used during the swimpath. Over the middle weir feature the peak velocity reached 2 m/s, however because of the short distance, the fish could burst over the feature and into the recovery pool with little energy expenditure. This finding was consistent with how constructed rock arch structures are designed to function by providing hydraulic drop and resistance while allowing for a fish to pass with efficient bursts and recover in an upstream pool.

Although average velocity was the primary evaluation tool during the fish passage analysis, there were minimum depths along most of the swimpaths which exceeded 0.5 m. This amount of depth would allow adequate headroom for walleye to exploit a 0.15 m to 0.28 m (6 in to 11 in) near-bed area where reduced flows could be found. When near-bed velocities were placed into the model all 15 of the swimpaths were passable for all three size groups. The impact of near-bed flows on fish passage success is displayed for Swimpath 5 in Figure 5-1. In this example, using

average velocity calculations only the largest body sized fish was predicted to pass. However, when the near-bed velocity reduction was applied, all three body sizes were able to pass with only a small percentage of their ability to complete the swimpath used.

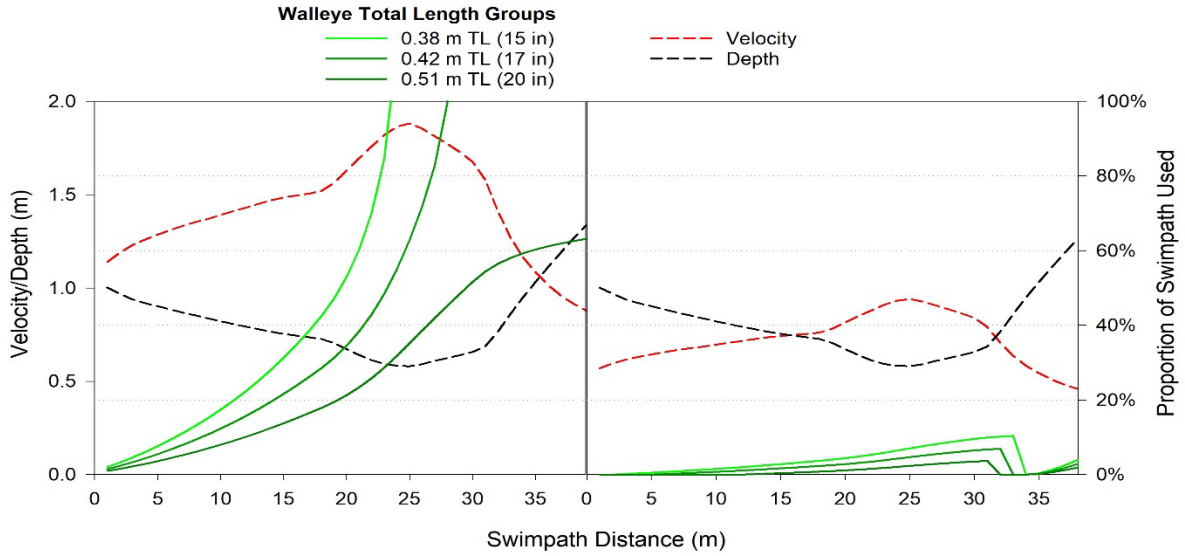

Figure 5-1. Comparison of fish passage success between depth averaged and near-bed velocities. Y-axis represents the amount of swimpath used and if 100% is reached a barrier to passage exists.

Based on these findings the proposed design is expected to function effectively to pass walleye and similar species at all habitat features. If a velocity barrier exists, near-bed velocities and less challenging routes are available.

5.2 Sturgeon Group Passage

Passage of lake sturgeon was evaluated at a boulder cluster and the W-weir. The model predicted full passage for both length groups at the boulder cluster swimpath (Swimpath 6) when using depth averaged flow velocity (5-2). As with the walleye group, the boulders provided discernable flow refugia in the line graphs by producing abrupt velocity reductions and an obvious benefit to the modelled energy expended along the route. The depth along the swimpath was greater than >0.5 m except when approaching a boulder. Deeper depths could be used by a sturgeon by altering its course slightly. The boulder cluster is a common design feature and found throughout the project area. Accordingly, passage of sturgeon would be likely at most analogous boulder features and provide upstream passage.

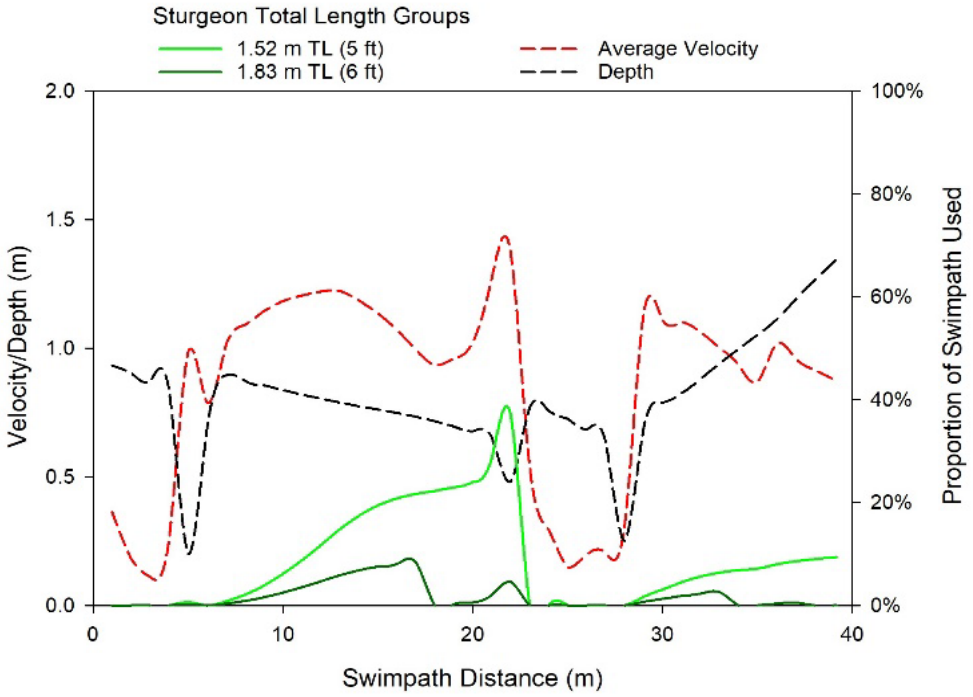

Figure 5-2. Fish passage success of lake sturgeon at boulder cluster (Swimpath 6). Y-axis represents amount of swimpath used – if 100% is reached a barrier to passage exists.

The Swimpath 1 route was used to evaluate W-weir passage and was found to be a barrier when using average velocity (Figure 5-3). The barrier was due to velocity over the middle weir crest briefly spiking to >2 m/s. Therefore, if using average velocity values, sturgeon would need to alter their route to the lower velocity areas found near the weir edges or the adjacent boulder clusters. However, using near bed velocity is an appropriate estimator for lake sturgeon if adequate depth is available for the large-bodied fish. The most challenging area along the swimpath is found at the middle weir crest with an average depth of 1.1 m (47.2 in) across a 3 m path where headroom would average 0.22 - .25 m (9-10 in). Peak velocities would be around 1.1 m/s, however, large recovery pools appropriate for sturgeon would be available immediately

above and below each crest for refugia (Daugherty et al. 2009). Sturgeon would be proficient at using the near bed conditions as they moved upstream by touching, or being close to, the river bottom where they would navigate their direction through subtle adjustments of their body in the current, and use small bursts to ascend barriers to an upstream recovery pool (Auer 2013). When using near bed velocity in the model both size groups were predicted to ascend the barrier with little energy expended (Figure 5-3). Other areas of the W-weir contain lower average and near-bed velocities with deeper depths and should provide passage at most locations.

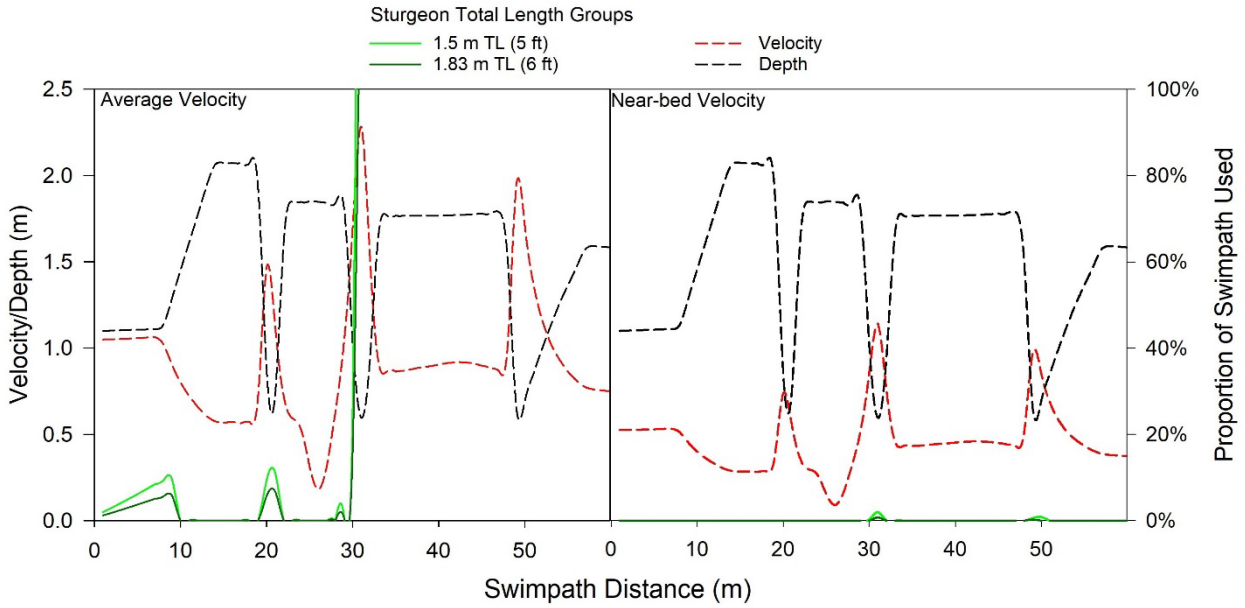

Figure 5-3. Comparison of fish passage success between depth averaged and near-bed velocities. Y-axis represents the amount of swimpath used and if 100% is reached a barrier to passage exists.

6.0 SUMMARY AND CONCLUSION

The findings of this report reinforce how the proposed design facilitates fish passage and that the naturalized design will function as predicted. Within the model used, fish passage was predicted to occur at most difficult hydraulic scenarios and for each of the design elements – boulder clusters, W-weir, and riffles. These findings also suggest that the design will allow a suite of other species to pass that have similar or greater swimming performance including the State Threatened river redhorse, other sucker species, and salmon. The current low-head dams provide a significant barrier to migration up to the 6th Street dam. The proposed design offers hydraulic conditions that facilitate fish passage for a broad group of species and at a wide range of flow conditions and incorporates natural features within the constraints of an urbanized channel.

Grand River-Lower Reach Project Monitoring Plan 4/2024

Grand River- Lower Reach Project

City of Grand Rapids

MONITORING PLAN

April 2024

This monitoring plan describes the monitoring that will be conducted as part of the project.

Construction Monitoring

1. Ensure the project is constructed in compliance with the project's plans, specifications, and permit requirements using industry standard methods.
2. Visually monitor turbidity downstream of the project area. If turbidity is visible at the next City of GR bridge downstream of the project area, the City will work with the contractor to adaptively management the current operation and ensure best management practices are in place and functioning appropriately.

Post Construction Monitoring

1. Within a year of completion or as soon as flow conditions are suitable, in-channel hydrographic survey work will be conducted,
2. Prepare and Submit as-built information including:
    a. survey documenting as-built conditions where the bed and banks are altered and restored.
    b. survey of the water surface profile at normal flow through the project reach.
3. Conduct project inspections for a period of 2 years. Visual inspections of each structure will be conducted from the river's edge following bankfull discharge events meeting or exceeding 13,000 cfs to ensure the structures area still functioning according to the original design intentions.

Cumulative Impacts Analysis
City of GR to EGLE
June 2024

OFFICE OF
CITY
ENGINEER

CITY OF GRAND RAPIDS

May 13, 2024

To: Michigan Department of Environment, Great Lakes, and Energy

RE: Cumulative Impacts Analysis
City of Grand Rapids Projects along the Grand River

To whom it may concern:

At EGLE's request, in connection with its review of the City's application for permits under Parts 301, 303, and 31 of the Natural Resources and Environmental Protection Act ("NREPA") for the Grand River Revitalization Project (the "Project"), the City of Grand Rapids compiled a list of projects planned along the Grand River on City-owned property or where the City may be the State permit applicant. EGLE also specifically asked the City to include the River for All projects on this list. The City has included the River for All (RFA) projects, though these projects are only in the City's Parks and Recreation 2022 Strategic Master Plan, and the specific design and schedule for implementation for most of them are currently unknown. The narrative of the projects and impacts shown below for the River for All projects are based on conceptual graphics, and future projects may be significantly different. Some of these projects may not receive funding and would not be built.

The following changes have been made since the previous version dated March 7, 2024 was submitted:

1. Updates for the Lower Reach Project Design
2. Miscellaneous typographical improvements

Maps and Figures showing the location of the projects are attached as Appendix A; a table of the projects and simplified activity information is attached as Appendix B; a narrative describing the projects and anticipated impacts from the projects is attached as Appendix C; and available design drawings are attached as Appendix D.

The projects on the list vary in status from purely conceptual renderings to permit-level design. Project status has been labeled as either "Master Plan only", "concept design", "active design" or "permitting". Definitions of each status are included in Appendix B. Only projects in the active design or permitting phases have progressed enough to be able to calculate any regulated activity. Impacts related to the Master Plan and concept design projects have been estimated based on current renderings or concept plans; these estimates are likely to change as design progresses. For projects in the active design phase, the City has included the estimated work in wetlands, bottomlands, and floodplains, but these estimates are subject to change prior to submittal of the permit application. The projects in the permitting phase have the State's permit application number included in the table so those project files may be easily

referenced. All other projects have a page number listed to indicate which page the drawing or set of drawings is in Appendix D.

Sincerely,

Tim Burkman, P.E.
City Engineer

Appendix C
Narrative of Anticipated Impacts from Grand River projects

This document describes the cumulative impacts on regulated aquatic resources which may result from other projects in the vicinity of the Lower Reach Project. All impacts discussed or quantified herein are based on information currently available at the time of permit submission. Impacts for projects not at permitting level were estimated based on assumptions. Impacts have been identified which may occur from projects the City of Grand Rapids has in permitting, active design, concept design, or in the Master Plan only. Potential impacts to aquatic resources discussed here include:

- Impacts on the Public's right to Navigate, Fish, and Fowl on the Grand River;
- Impacts on Bed Mobility, Downstream Turbidity, and Sediment Transport;
- Impacts on Wildlife and Habitat, including Threatened and Endangered Species;
- Impacts to Wetlands;
- Impact on Stream Function;
- Impacts on Modeled Flood Risk;
- Temporary Construction Impacts

Summary Project Narratives

Lower Reach Project (Permitting, HQ2-Y2FM-WS9TA):
This project would remove the four low-head dams, and place natural rock and boulders to install two expansive riffles with emergent boulders, three unique boulder arch structures, three boulder vane structures for access along the banks, and numerous scattered habitat boulders into the river. The project proposes the placement of approximately 5,000 tons of boulder and 15,000 tons of rounded alluvial rock.

In terms of adverse impacts to a regulated resource, the Project has been designed to have limited, temporary impacts. Specifically, construction of the Project will necessitate the following temporary adverse impacts: (i) the public's ability to navigate and recreate on the Grand River will be temporarily limited in certain areas due to temporary restrictions on river access during construction; (ii) there may be a temporary increase in bed mobility and downstream turbidity and sediment transport during construction; (iii) there will be temporary adverse impacts on aquatic wildlife; and there will be a temporary adverse impact to wetlands of 0.01 acres. The project will also have a seperate, permanent impact to wetlands of 0.01 acres.

Corps Project including RFA#2 (Concept Design):
The Great Lakes Fishery Commission has contracted with the U.S. Army Corps of Engineers (Corps) to conduct an Environmental Impact Statement (EIS) for the Corps project. Fourteen alternatives have been identified and will be considered for the project. Upon completion of the formal EIS process, the Great Lakes Fishery Commission will select the preferred alternative and issue a Record of Decision.

For the purpose of this analysis, the City and GRWW have analyzed the potential cumulative impacts for the City's preferred alternative, which is to remove the 6th Street Dam, construct an

adjustable hydraulic structure (AHS), and install diversified hydraulic features in the Grand River. The proposed AHS would incorporate a portage route connecting the upstream and downstream sides of the barrier for navigation. Similar to the Lower Reach Project, once constructed, the Corps Project alternative evaluated here is anticipated to have positive impacts on regulated resources.

The proposed site of the AHS, as evaluated for this application, is adjacent to the River for All (RFA) Site #2, the decommissioned Water Department Storage Yard. River for All Site #2 will be decommissioned as a storage yard for the City of Grand Rapids Water Department and is re-envisioned as a riverfront park. Currently, this site is being considered for access and staging for the construction of the proposed AHS. The existing site is primarily a compacted gravel parking lot/storage yard with ancillary structures for water main and storm water pumping stations. The former railroad bed serves as the top of the flood protection system, but the flood protection is envisioned to be relocated and increased as part of the project. When completed, river access will dramatically increase and transform this site into a regional recreation hub. Concept Design plans for RFA Site #2 call for:

1. An elevated canopy trail to connect pedestrians to the forested canopy above and protect wetland habitat below.
2. A lodge for year-round educational and cultural events.
3. Increase the flood protection system to 100-year base flood elevation plus 3 feet.
4. Potential repurposing of the water storage tank providing a unique space for large events and daily use.
5. A logjam inspired nature playground.
6. A dedicated drop-off area to accommodate large group access and circulating river traffic.
7. River terraces provide additional access to the water's edge
8. 600 lineal feet of new shared use trail.
9. Removal of railroad berm and terraced site to allow access into and out of the river as well as creating a naturalized edge and additional flood storage.
10. River landing provides a safe and accessible public river access space.
11. A large universally accessible walk provides river recreation opportunities to the north and south of the AHS.
12. Stormwater terraces treat onsite runoff and provide ecological interest and support habitat restoration.

Lyon Edge Project (Construction, HP8-8RNS-2WDK2):
This project will include removal of stairs and amphitheater to create a passive and active recreational area, connection of existing routes, and pedestrian safety improvements related to vehicular traffic in Lyon Square.

East River Edge Project (Campau) (Construction, HP8-PWB2-465KA):
This river edge sidewalk has been undercut by river flows, and the area is not currently open to the public as it presents public health and safety concerns. This project will restore the stability and safety of the trail and improve safe access to the river edge from the proposed paved multi-use trail.

Grand Rapids Public Museum Riverfront Improvements (Construction, HPD-8EMK-1EGF2):
This project will remove existing sidewalk and install a new trail down to the river's edge to improve access. The project will also add a new access to the east side of the museum and will include a dual-purpose step/seating area and outdoor classroom. The improvements will allow unrestricted access for all people and add native vegetation to improve aesthetics, and create aquatic and wildlife habitat

Leonard St. to Ann St. Trail (Construction, WRP040128 v. 1):
This project has been refined to be an upper non-motorized pathway on the top of a flood protection berm. This project is proposing to provide freeboard to reach FEMA's NFIP accreditation levels above the 100-year base flood elevation.

Coldbrook Water Pump Stations – RFA #3 (Master Plan only):
The project seeks to transform a property with mostly surface parking lots and storage buildings, which drain directly to the Grand River, into a prominent public recreation and outdoor education amenity. This existing site has a concrete floodwall limiting access to the river.

The new site layout will be an opportunity to provide education on the importance of best management practices related to stormwater and the positive changes happening along the Grand River and its tributaries. This site will be a critical hub for river and trail access. Envisioned improvements include the following:

1. Removal of approximately 150 lineal feet of concrete floodwall allowing access into and out of the river as well as creating a naturalized edge and additional flood storage.
2. Interpretation of Coldbrook Creek to demonstrate the channel's historic alignment and educate the public on the other hidden streams in the area.
3. Flexible plaza spaces adjacent to the building provide areas for outdoor learning, events, and cultural activities, such as canoe building with the Anishinaabe and programmed outdoor recreation activities could be pursued here.
4. Mixed use redevelopment above the 100-year floodplain is anticipated at the corner of Leonard Street and North Monroe Avenue with plazas oriented towards the river.
5. A large multipurpose lawn provides flexible space with an option for future bus drop off
6. ADA and small parking lot is located onsite.
7. An emergency access boat ramp.

Fish Ladder Park – RFA #5 (Master Plan only):
Fish Ladder Park has been identified as an important community gathering spot and the fish ladder structure is an iconic piece of functional art. The park would continue to serve these purposes and the project seeks to enhance and improve the site to function with any future changes to the river. If or when the 6th Street Dam is removed, the Fish Ladder structure would be modified to continue to provide fish passage, and improvements would be implemented within the surrounding park, which would continue to be a primary hub for fishing access. Envisioned improvements include the following:

1. Viewing deck located north of the Fish Ladder.
2. Existing fish ladder structure will remain for rapids viewing and fish observation.

3. Increase the flood protection system to 100-year base flood elevation plus 3 feet.
4. Changing room, restroom, and fish cleaning station.
5. Flexible plaza and adjacent parking area to accommodate small events.
6. Sloped event lawn next to new trees, planted on the high point of the existing berm to provide shade
7. Emergency access boat ramp.
8. Upper viewing perches on the embankment link to Scribner with Fish Ladder Park, provide small lounging pockets and expand spectator areas.
9. Approximately 800 lineal feet shared use trail.
10. Angling and wading access steps link the river trail to the bank.
11. Stormwater terraces treat onsite runoff and provide ecological interest and support habitat restoration.

Wealthy St. Access (Concept Design):
Wealthy St. Access is situated at the southern end of the downtown river corridor and a vital connector for residents within the Roosevelt Park and Black Hills Neighborhoods. The eastern edge is a City-owned parking lot with minimal use. The western edge is a small City-owned parking lot that is also minimally used, with dilapidated stairs that provide access about halfway down to the river. The stairs were originally installed for City workers to access an outfall that is now abandoned. The envisioned improvements will provide equitable river access in an area that currently consists of 15-foot tall concrete flood walls and a neglected river edge with some trees. Please note only one of the river edges is anticipated to be improved in this project, but both potential improvements are shown in the figure in Appendix D. At this time, it is unknown which side of the river the project would occur on. Envisioned improvements include the following:

1. Approximately 250 lineal feet of elevated boardwalk/ramps providing access from the existing parking lot to the river
2. Reconfiguration of the existing parking lot with improved drop-off location
3. Site amenities including pedestrian-scale lighting, benches, litter, and interpretive signage
4. Vegetated rip rap

201 Market Ave. (Permitting, HPZ-0BP4-6TQCH):
The existing river's edge on the east side of the Grand River between Fulton Street and Wealthy Street is approximately 2/3 of a mile. The current parcel contains buildings used to store the City's public works equipment. The river edge condition is a combination of cast in place concrete wall and steel sheet piling. Dependent upon the water level, portions of the river's edge include a sloped bank at the base of the walls. The entire length is populated with a combination of mature large trees and dense scrub-shrub underbrush providing screening of views for the current industrial and commercial uses.

The conceptual designs for the river's edge propose removal of the existing floodwall to provide better access to a more natural shoreline while adding freeboard to the flood control system in order to reach the 3 feet above the 100-year base flood elevation. Flood control will be maintained by utilizing a variety of design features rising to the flood control level with gentler slopes, naturally terraced dolomitic limestone and native plantings combined with walking running and biking trails paralleling the river and joining the properties along the Grand River. The proposed trail will be connected to river access points and public right of ways using

universal design guidelines, creating universal access for all to enjoy the Grand River. This development will coincide with changes in the adjacent parcels in the industrial use to commercial use, public green space, and potentially residential use.

Canal Park (Construction, WRP040025 V.1):
Project proposes to remove and replace approximately 3,810 LF of sidewalk and pathways in Canal Park. The new sidewalk and pathways will be 14-foot wide shared-use trail and raised to meet FEMA's NFIP accreditation requirements. A river terrace area and seat wall is proposed along river's edge. In addition, an event pavilion and plaza are also proposed. A river overlook decks is proposed to provide safe and unobstructed view of the river. A barrier-free floating kayak launch is also proposed. Proposed work activities have been designed to minimize impacts below the OHWM to the greatest extent possible. Furthermore, design meets the 100-year BFE plus required freeboard. Design to the 100-year flood plus required freeboard will provide sufficient flood protection within park area and protect infrastructure and park amenities. The barrier-free floatable kayak launch is the only proposed work past water's edge.

6th St. Park (Concept Design):
This park currently consists of a north/south linear trail, a restroom, fish cleaning station, small pavilion, public parking lot, and a concrete floodwall that spans the entire length of the park from I-196 to 6th Street with only one (1) point of access (which is not universally accessible) to the river located at the 6th Street Dam. Due to the concrete floodwall, there is minimal to no biodiversity along the river's edge. Additionally, there are several storm sewers that discharge into the river through the existing concrete floodwall. The southern half of the park consists of an electrical substation and remnant surface parking lots. The City acquired the parking lot parcels through a Michigan Natural Resources Trust Fund acquisition grant and has been temporarily activating the site. Permanent improvements will not proceed for several years as this is one of the anticipated staging and access sites for the Corps Project. This site will provide an opportunity to transform how the City and its citizens engage with its most valuable natural resource in one of its most prominent downtown locations. Envisioned improvements include the following:

1. 1,800 lineal feet of new shared use trail.
2. Increase the flood protection system to 100-year base flood elevation plus 3 feet.
3. Removal of approximately 740 lineal feet of concrete floodwall allowing access into and out of the river as well as creating a naturalized edge and additional flood storage.
4. River landing providing a safe and accessible public river access space.
5. A large universally accessible walk for river access.
6. Daylighted stormwater outfall and stormwater marsh provide resilient, natural stormwater treatment and re-establish a healthy river edge.
7. Stepped seating terraces at the river edge to provide an expanded, resilient rapids viewing area.
8. A shaded seating edge expands park access, even during high water events.
9. An event pavilion to accommodate concessions, restrooms, and services to support recreation.
10. An event lawn sized for markets, concerts, and a number of other uses.
11. Stormwater terraces treat onsite runoff and provide ecological interest and support habitat restoration.
12. A flexible mid-level terrace can host seasonal events and recreation.

13. A skate park in the area near I-196.
14. Non-motorized watercraft takeout point

Riverside Park (Master Plan only):
Riverside Park is Grand Rapid's largest and most prominent park for active and passive recreation users. The 182-acre park with approximately 2,000 lineal feet of river frontage lies almost entirely within the 100-year flood limit with a few exceptions along Monroe Avenue. The river edge is primarily naturalized with the exception of some armored locations and 3 public boat launch facilities. The park also has an interior lagoon with two heavily vegetated islands. Numerous smaller improvements have been made within the park over the last 20 years, but the last major investments were implemented in the late 1990's. Due to the park's popularity, use, and location within a highly fluctuating floodplain, most of the built assets are nearing the end of their functional life cycle. Roads, bridges, trails, and other structures are in need of repair, replacement. or removal. Additionally, over 100 acres of the park consists of maintained turf. This practice, along with the surface runoff from interior roads and parking, and siltation from seasonal flooding have contributed to poor water quality within the park's lagoon. The park is also situated at the downstream end of several large storm outfall pipes. These pipes collect stormwater from an approximately 1,800-acre watershed to the east and discharge directly into the Grand River. The City's master plan contains a broad list of ambitious and exciting changes for the park that focus on the following community priorities:

1. Remove, replace, and expand non-motorized trails network within the park
2. Daylight existing stormwater low-flow and route through new bio-swales, rain gardens, constructed wetlands to collect, cleanse and infiltrate water prior to reaching the lagoon and/or Grand River.
3. Reduce road and parking impervious surfaces
4. Increase native wetland, wet meadow, and upland plantings, especially along areas receiving surface runoff.
5. Renovate existing restrooms and maintenance facility.
6. Provide multi-purpose community waterfront center with restrooms, concessions, large event area, accessible watercraft launch, and river amphitheater.
7. Improve existing active recreation programs including sport fields, cross country course and disc golf.
8. Improve accessibility to the lagoon and river's edge as well as increase edge resiliency through use of bio-engineering techniques.
9. New dog park dedicated as off-leash area
10. Improve all 3 existing boat launches
11. Renovate existing play areas and incorporate nature-based play elements

Ah-Nab-Awen Park - South (Active Design)
Ah-Nab-Awen Park is on the west side of the Grand River between Pearl and Bridge Streets and a vital outdoor event space, trail connector, and cultural site for guests and residents in the heart of downtown. The proposed design for the south end of the park between Gillett Bridge and Pearl Street includes removal of the representative burial mounds, aging restroom and improvements to sidewalks that are not ADA compliant, and cultural interpretation. Special

attention was also given to transform the “Fake Mounds”, as they are referred to by the Grand River Band of Ottawa Indians who helped shape the proposed improvements from an under-utilized and misrepresented historical area to a space for healing, celebration, and a welcoming environment for both tribal members and the general public.

Impacts on the Public's right to Navigate, Fish, and Fowl on the Grand River

Lower Reach Project (Permitting, HQ2-Y2FM-WS9TA):
Removal of the four low-head dams is anticipated to make the Grand River in this reach more accessible, and therefore, improve the public's right to navigate, fish, and fowl.

Corps Project including RFA#2 (Concept Design):
Due to the proposed portage route around the AHS structure that currently does not exist, this project is expected to have a significant positive impact on the public's right to navigate, fish, and fowl on the Grand River. The site improvements related to RFA #2 will also improve access to and from the river, also positively impacting the public's right to navigate, fish, and fowl on the Grand River.

During construction of the project, it may be necessary to temporarily restrict or prohibit use of a portion of the river for public safety.

Lyon Edge Project (Construction, HP8-8RNS-2WDK2):
This project is expected to have a positive impact on the public's right to navigate, fish, and fowl on the Grand River by enhancing the riverfront to provide a gathering space for the public along the river's edge. The stairs down to the river in this area will be removed, but two access points to the river are nearby along the Devos Place Convention Center and across Pearl St. No adverse impacts are anticipated on the Public's right to fish, fowl, and navigate the Grand River from this project.

East River Edge Project (Campau) (Construction, HP8-PWB2-465KA):
The East River Edge sidewalk improvements will have a positive impact on the Public's right to navigate, fish, and fowl on the Grand River by rehabilitating and improving access along the river. No adverse impacts are anticipated on the Public's right to fish, fowl, and navigate the Grand River from this project. This public walkway is currently closed due to a public safety hazard and will not reopen until this project occurs. Severe erosion has substantially undercut the sidewalk creating a public safety hazard.

Grand Rapids Public Museum Riverfront Improvements (Construction, HPD-8EMK-1EGF2):
The Grand Rapids Public Museum is reimagining their riverfront and are proposing to remove the large riprap and scrub-shrub vegetation and install a concrete sidewalk with foundation along a portion of their property. This change is expected to have a positive impact on the Public's right to navigate, fish, and fowl as it is creating two access points with universal access design principles to the river's edge that do not currently exist. No adverse impacts are anticipated on the Public's right to fish, fowl, and navigate the Grand River from this project.

Leonard St. to Ann St. Trail (Construction, WRP040128 v. 1):
The walkway will provide better access along the river's edge. No adverse impacts are anticipated on the Public's right to fish and fowl the Grand River from this project either.

Coldbrook Water Pump Stations – RFA #3 (Master Plan only):
This site is anticipated to have a positive impact on the Public's right to navigate, fish, and fowl on the Grand River. By removing approximately 150 lineal feet of concrete floodwall to allow access into and out of the river and adding a naturalized river edge with universal design concepts, access to the river will improve allowing anyone to fish or fowl on the Grand River. With improved access, this will positively impact the public's river to navigate the river. There are no anticipated improvements that would adversely affect the public's right to navigate, fish, or fowl on the Grand River.

Fish Ladder Park – RFA #5 (Master Plan only):
This project is anticipated to have positive impacts on the public's right to fish, fowl, and navigate the Grand River. One of the main goals of this project is to provide universal access to the riverfront for all people to enjoy. The proposed improvements of adding more access and associated support facilities (i.e., changing rooms, restrooms, fish cleaning stations) are all added to support the public's use of the river. No adverse impacts are anticipated on the Public's right to fish, fowl, and navigate the Grand River from this project.

Wealthy St. Access (Concept Design):
This project is anticipated to have positive impacts on the public's right to fish, fowl, and navigate the Grand River. This project would add access to a site where minimal facilities currently exist to improve the public's right to fish, fowl, and navigate the Grand River. There are no anticipated adverse impacts on the public's right to fish, fowl, and navigate the Grand River.

201 Market Ave. (Permitting HPZ-0BP4-6TQCH):
One of the main goals of this potential project is to provide universal access to the riverfront for all people to enjoy. The proposed amenities, including the river edge and bridges, will be designed to add access to aid in the Public's abilities to fish, fowl, and navigate the river. Therefore, this project would have a positive impact on the Public's right to fish, fowl, and navigate the Grand River.

Canal Park (Construction, WRP040025 V.1):
One of the main goals of this potential project is to provide universal access to the riverfront for all people to enjoy. With the removal of the concrete retaining wall, and the addition of a large universally accessible walk, this will positively impact the public's right to fish, fowl, and navigate the Grand River. There are no anticipated adverse impacts to the public's right to fish, fowl, and navigate the Grand Rapids associated with this project.

6th St. Park (Concept Design):
One of the main goals of this potential project is to provide universal access to the riverfront for all people to enjoy. The current river access is limited in its ability to provide sufficient access to all people. With the removal of the concrete retaining wall, and the addition of a large universally accessible walk and stepped terrace seating, this will positively impact the public's right to fish, fowl, and navigate the Grand River by creating more universally accessible space at the edge of the Grand River. There are no anticipated adverse impacts to the public's right to fish, fowl, and navigate the Grand Rapids associated with this project.

Riverside Park (Master Plan only):
Riverside Park currently offers a wide variety of options for people to access the Grand River. With this project, the options would be to further enhance those to provide universal access and boating access or to renew the current assets. Therefore, positive impacts for the public's right to fish, fowl, and navigate the Grand River are anticipated. No adverse impacts for the public's right to fish, fowl, and navigate the Grand River are anticipated.

Ah-Nab-Awen Park - South (Active Design)
Ah-Nab-Awen Park currently offers for people to access the Grand River. With this project, the options would be to further enhance those to provide universally accessible walks to the existing main path leading down to the river. Therefore, positive impacts for the public's right to fish, fowl, and navigate the Grand River are anticipated. No adverse impacts for the public's right to fish, fowl, and navigate the Grand River are anticipated.

Impacts on the Bed Mobility, Downstream Turbidity, and Sediment Transport

Lower Reach Project (Permitting, HQ2-Y2FM-WS9TA):
This project is not anticipated to have any adverse permanent impacts on bed mobility, downstream turbidity, and sediment transport. Temporary increases in downstream turbidity may occur during construction, but proper best management practices will be utilized to minimize impacts.

Corps Project including RFA#2 (Concept Design):
The Corps Project, as being analyzed in this document, is not expected to have adverse impacts on bed mobility, turbidity, or sediment transport. The hydraulic gradient over the dam would be distributed over the proposed AHS and several hydraulic features, each designed with a 2x factor of safety against mobility. In this way, the hydraulic features and AHS would function to maintain grade control throughout the reach. Additionally, modeling and design of features would verify that any increases in the scour potential over existing riverbed would not exceed threshold mobility for existing substrate. Similar to the Lower Reach Project, care will be taken through design and modeling to verify that ongoing accumulation of fine sediment within the project reach is avoided and minimized.

Temporary turbidity during construction would be managed with industry standards and assumed to be performed in a similar fashion to means and methods proposed in the Lower Reach Project.

Lyon Edge Project (Construction, HP8-8RNS-2WDK2):
The Lyon Edge project is not expected to have any impacts to bed mobility, sediment transport, or downstream turbidity as all project work is occurring above the ordinary high water mark (OHWM) or behind the floodwall.

East River Edge Project (Campau) (Construction, HP8-PWB2-465KA):
The East River Edge sidewalk improvements is anticipated to have a positive impact to bed mobility, downstream turbidity, and sediment transport. Since 1990, the project area has experienced lateral erosion of 1.7 to 2.8 feet of material along the 439-foot length of river edge that has been transported downstream. This demonstrates the project area has eroding and transporting to downstream areas in the past and may be continuing to this day. The project will stabilize the river edge using slabbed pieces of dolomitic limestone and vegetative plugs, resulting in reduced downstream turbidity and substrate mobility. Temporary turbidity during construction would be managed utilizing appropriate best management practices.

Grand Rapids Public Museum Riverfront Improvements (Construction, HPD-8EMK-1EGF2):
The Grand Rapids Public Museum Riverfront Improvements is expected to have no net adverse impact on the bed mobility, downstream turbidity, or sediment transport. Minimal work would be conducted within the flowing channel and any temporary turbidity during construction would be managed with appropriate best management practices.

Leonard St. to Ann St. Trail (Construction, WRP040128 v. 1):
This project is not expected to adversely impact bed mobility, downstream turbidity, and sediment transport as the work is above the OHWM.

Coldbrook Water Pump Stations – RFA #3 (Master Plan only):
This site is anticipated to have no adverse impact on the bed mobility, downstream turbidity, and sediment transport. There is no in-river work planned with this project. The intent of the design is to soften some of the concrete edges through the use of naturalized material. It is anticipated that softening of the river edge and providing more flood storage will not adversely impact the bed mobility, downstream turbidity, and sediment transport.

Some temporary impacts to turbidity may occur during construction, but appropriate best management practices will be taken and/or installed during construction.

Fish Ladder Park – RFA #5 (Master Plan only):
There is no anticipated adverse impact on bed mobility, downstream turbidity, and sediment transport as the proposed work is not significantly changing the cross-section at this park and the material will be designed to be stable. There may be temporary adverse impacts during construction, but these will be managed by appropriate best management practices.

Wealthy St. Access (Concept Design):
There is no anticipated adverse impact on bed mobility, downstream turbidity, and sediment transport as any change in the cross-section or any protrusions into the flow that increase shear stresses will be minimal. There may be a slight positive impact on these aspects as an increase in native vegetation may help reduce turbidity in the river. There may be temporary negative impacts during construction, but these will be managed by appropriate best management practices.

201 Market Ave. (Permitting HPZ-0BP4-6TQCH):
There is no anticipated adverse impact on bed mobility, downstream turbidity, and sediment transport. The intent of the design is to soften the concrete edges through the use of naturalized material. It is anticipated that softening of the river edge and providing more flood storage will not adversely impact the bed mobility, downstream turbidity, and sediment transport. There may be a marginal positive impact in downstream turbidity for higher flow events given the additional space in the floodplain. There may be temporary negative impacts during construction, but these will be managed by appropriate best management practices.

Canal Park (Construction, WRP040025 V.1):
There are no anticipated adverse impacts on bed mobility, downstream turbidity, and sediment transport as the intent of the design is to soften the concrete edges through the use of naturalized material. It is anticipated that softening of the river edge and providing more flood storage will not adversely impact the bed mobility, downstream turbidity, and sediment transport. There may be a slight positive impact on these aspects as an increase in native vegetation may help reduce turbidity in the river. There may be temporary negative impacts during construction, but these will be managed by appropriate best management practices.

6th St. Park (Concept Design):
There is no anticipated adverse impact on bed mobility, downstream turbidity, and sediment transport. The intent of the design is to soften the concrete edges through the use of naturalized material. It is anticipated that softening of the river edge and providing more flood storage will not adversely impact the bed mobility, downstream turbidity, and sediment transport. There may be temporary negative impacts during construction, but these will be managed by appropriate best management practices.

Riverside Park (Master Plan only):
With the intent of project to improve the stormwater management, water quality of the stormwater, and the lagoons in the park, work below the OHWM is expected, but it would likely be within the park itself, not on the river edge. Given that the intent of the system is to improve water quality, it is anticipated there will be no adverse impacts to the Grand River related to bed mobility, downstream turbidity, and sediment transport. There may be temporary negative impacts during construction, but these will be managed by appropriate best management practices.

Ah-Nab-Awen Park - South (Active Design)
This project is not expected to adversely impact bed mobility, downstream turbidity, and sediment transport as the work is above the OHWM.

Impacts on Wildlife and Habitat, including Threatened and Endangered Species

Threatened and Endangered Mussel impact was calculated using an estimated polygon of work area compared to extents of the Grand River at 890 cfs. This 890 cfs line is the low water level (7Q10) used to assess changes in the wetted area available for aquatic organisms under low flow conditions as detailed in the Revised Biological Assessment. Where the areas overlapped was assumed to be possible area of mussel impact for the sake of this exercise.

The density of the mussel habitat in the Grand River in the City of Grand Rapids varies based on reach. Based on quantitative samples, in 2013, 2015, and 2016, an average mussel density has been assumed for the following reaches. Impacts to mussels have been estimated based on these densities.

Reach	*Mussel Density (unionids/m^2)*
Proposed AHS to 6th St. bridge	*3.0*
6th St. bridge to 6th St. dam	*1.7*
6th St dam to Fulton St.	*0.3*
Fulton St. to Plaster Creek	*0.1*

It is important to note that these are approximate estimations, based on 30% preliminary design for the in-channel improvements, and include conservative assumptions for construction means and methods which have yet to be determined.

Lower Reach Project (Permitting, HQ2-Y2FM-WS9TA):
This project is pursuing a Biological Opinion from the United States Fish and Wildlife Service due to the presence of the federally endangered snuffbox mussel. No impacts to non-aquatic species are anticipated. All impacts to mussels will be avoided and minimized. The Biological Assessment currently under review by United States Fish and Wildlife Service includes mussel relocation ahead of the project to occur in summer 2024.

Within the direct impact area (45,445 m2) of the project, there are estimated to be 123 E. Triquetra, 1,800 Michigan TES, and 11,711 other unionid species. Within the indirect impact area (82,155 m2) of the project, there are estimated to be 222 E. Triquetra, 3,253 Michigan TES, and 21,171 other unionid species. Upstream of the project, the indirect impacts are estimated at 104 E. Triquetra, 1,521 Michigan TES, and 9,901 other unionid species. Downstream of the project, there are estimated to be no E. Triquetra, 8,325 Michigan TES, and 28,250 other unionid species.

Mussels will be relocated from the direct impact areas. Loss of mussels will also be mitigated through the establishment of a mussel mitigation fund.

Within the direct impact area of the project, two Threatened species have been observed; lake sturgeon *(Acipenser fulvescens)* and river redhorse (*Moxostoma carinatum).* There are no impacts expected to either species. *A. fulvescens* have been observed at the 6th Street Dam during spring ascending discharge and when water temperatures reach 10-11°C (55°F). *A.*

fulvescens migrate downstream and out of the Project area prior to July when construction activities would begin. During summer and fall surveys in the Project area no juvenile *A. fulvescens* have been observed. *M. Carinatum* has been observed in the lower Project area during late May and early June during their spawning window. However, from July through September, *M. Carinatum* adults are only found in low abundance. Over a four-year fish study from Bridge Street down to Rush Creek (GVMC 2023) a total of 4,557 fish were captured. Twenty were adult *M. Carinatum* with only four observed in the Project area. Adult *M. Carinatum* are capable of moving away from any impacts caused by construction.

Corps Project including RFA#2 (Concept Design):
The Corps Project is expected to have a positive impact on wildlife and habitat. Aquatic wildlife would have a more diverse range of habitat types which are more representative of a naturally functioning river. Added habitat types would include pools, riffles, runs, and glides, all of which are not as prevalent under existing conditions. The macroinvertebrate community is categorized as poor in the Lower Grand River because "stable habitat necessary for a diverse macroinvertebrate community" is lacking and riffle habitat has not formed. The macroinvertebrate community is anticipated to benefit and respond with a higher species richness and diversity after construction. The addition of coarse substrate riffle habitat is expected to provide an important habitat type for aquatic macroinvertebrates and produce benefits to the habitat of the reach as a whole.

While there will be temporary impacts associated with the proposed removal of 6th Street Dam and construction of the proposed AHS and hydraulic features, the project is expected to provide access to approximately 80 acres of aquatic habitat for non-jumping fish species, including Lake Sturgeon spawning habitat currently blocked by the 6th Street Dam. The project, with the 16 acres of permanent streambed change as analyzed in this document, is also expected to create 240% more preferred hydrophysical habitat for mussels than existing conditions. There may be temporary impacts on the aquatic wildlife, but the project team will continue to consult with the United State Fish and Wildlife Service (USFWS) and Michigan Department of Natural Resources (MDNR) on ways to avoid, minimize, and mitigate any potential impacts.

Construction access to the proposed AHS site will be most likely through the Water Dept. Storage Yard and access to 6th Street Dam most likely through Fish Ladder Park and 6th Street Park. For this reason, these river edge improvements would likely be constructed following the in-river work for the Corps Project. Since all projects are still in concept design phase and any timeline for construction at the time of this submittal is unknown, the mussels impact from projects were shown separately to provide a conservative estimate.

The species discussed below could experience some potential impacts from the Corps project. These impacts can likely be further mitigated during the design/development process and using best management practices during construction.

Unionids (Mussels):
Construction of the AHS will affect approximately 18,500 m^2 of riverbed. Unionid density in this area is approximately 3.0 unionids/m^2. Approximately 150 *E. triquetra*, 5,300 Michigan TES species, and 51,000 other unionids could be affected by construction of the AHS. However, approximately 80% of those unionids could be translocated before construction: 120 *E. triquetra*,

4,200 Michigan TES species, and 41,000 other unionids. Unionids that would not be translocated include approximately 30 *E. triquetra*, 1,100 Michigan TES species, and 10,200 other unionids.

The area between the 6th Street Bridge and the 6th Street Dam would also be directly impacted during construction, approximately 42,000 m^2. Unionid density in this area averaged 1.7 unionids/m^2, A total of approximately 200 *E. triquetra*, 6,800 Michigan TES species, and 66,000 other unionids could occur in this area. Collecting and translocating unionids from this area would be limited to those within work isolation areas due to the dangerous diving conditions this close to the 6th Street dam. For the purposes of this assessment, unionids were assumed to be collected from one third of the area, as some of the area may require work in wet and some of the area may be covered with isolation measures before unionids can be collected. An estimated 80% of the unionids in one third of the area could be translocated under isolated conditions; 50 *E. triquetra*, 1,800 Michigan TES species, and 17,600 other unionids. Unionids that would not be translocated and affected by the Upstream Project above the dam include 144 *E. triquetra*, 5,000 Michigan TES species, and 48,400 other unionids.

Most of the area between the 6th Street Dam and the Lower Reach project will also be directly impacted by construction below the dam; 107,400 m^2. Freshwater mussels occur at a low density (0.3/m^2) between the 6th Street Dam and the Lower Reach project. Approximately 290 *E. triquetra*, 4,300 Michigan TES species, and 27,700 other unionid species may reside in this direct impact area. Diving conditions below the dam are also dangerous due to the high current velocities. Conservatively, unionids could be collected from within work isolation areas, approximately one third of the area. Approximately 80% of the unionids within the cofferdams would be translocated; 80 *E. triquetra*, 1,150 Michigan TES species, and 7,400 other unionids. Unionids that would not be translocated and assumed to be directly impacted by the Upstream Project below the 6th Street Dam include 215 *E. triquetra*, 3,150 Michigan TES species, and 20,300 other unionids.

The total number of unionids affected after translocation in all 3 areas is approximately 400 *E. triquetra*, 9,200 Michigan TES species, and 79,000 other unionids.

Hydraulic changes to flow depths and velocities would occur between the AHS and channel reconfiguration areas (indirect affect areas). The indirect affects area is approximately 232,000 m^2, with a mussel density of 1.7/m^2. Approximately 400,000 mussels may be indirectly affected, including 1,100 *E. triquetra* and 37,000 other Michigan TES species.

Measures that could be used to mitigate impacts include translocating mussels from the AHS construction area to a suitable recipient site. Collection and translocation of unionids directly affected by the project may be limited to slower flowing areas near the banks and within cofferdams.

The loss of mussels could also be mitigated by the improvement in habitat conditions within the Corps Project area. The area above the 6th Street Dam is now a slow flowing pool. An increased velocity with the removal of the 6th Street Dam should improve habitat conditions for unionid mussels and their host fish. A preliminary Preferred Hydraulic Habitat (PHH) model was developed based on hydraulic conditions within the highest density areas within the sampled area between the AHS and the 6th Street Dam. The model included an index of substrate stability (shear stress/critical shear stress) ≤1.2 under high flow conditions (stable substrate under high

flow), velocity under low flow conditions between 0.15 m/sec and 0.036 m/sec (low enough velocity to allow juvenile settlement but some flow during low flow conditions), and areas with ≤10% bed slope. Bedrock areas and areas that would not be inundated under 7Q10 (low flow conditions) were excluded from the model. Under existing conditions, approximately 32,700 m^2 of PHH occurs above the 6th Street Dam and 2,800 m^2 of PHH occurs between the 6th Street Dam and Dam 2. This should increase to approximately 86,000 m^2 of PHH or a 240% increase after the project is completed.

Myotis septentrionalis (Northern Long-eared Bat)

Northern long-eared bats could be affected if they used any of the trees in the area for roosting if roost trees were removed as part of construction activities. However, few *M. septentrionalis* appear to spend the summer in the southern portion of Michigan. Additionally, the Project is within an urban setting, not likely to harbor this species of bat. A few trees would likely need to be removed from construction/staging areas for the proposed AHS on the east bank but none of these trees appear to be suitable roost trees. As a precaution, trees should be removed from construction/staging areas in winter months to avoid effects on roosting bats. Northern long-eared bats are unlikely to be affected by this Project.

Myotis sodalis (Indiana bat)

Although summering *M. sodalis* occur throughout the southern portion of Michigan, including Kent County, it is not likely to be affected by the Project. Impacts to bats would primarily include removal of roost trees as part of construction activities. A few trees would likely need to be removed from construction/staging areas for the AHS (Upstream Reach) on the east bank. This area is already heavily urbanized and trees that are to be removed are unlikely to be roost trees. As a precaution, trees should be removed from construction/staging areas in winter months to avoid effects on roosting bats or evaluated for bat habitat prior to removal. Indiana bats are unlikely to be affected by this Project.

Lycaeides melissa samuelis (Karner blue butterfly)

This species primarily occurs in oak savannas and pine barrens with sandy soil. It is dependent upon wild lupine (*Lupinus perennis*), as larvae feed exclusively on this plant species. Although *L. m. samuelis* is known to occur in Kent County, no suitable habitat exists in the Project Area. This species would not be affected by the Project.

Acipenser fulvescens (Lake Sturgeon) - Threatened

A small *A. fulvescens* population is known to occur in the mainstem of the lower Grand River and the mouth of the Grand River, but within the project area**,** it has not been found upstream of the 6th Street Dam (Figure 3-8, Hanshue and Harrington, 2011). The 6th Street Dam is a barrier to spawning grounds of several Lake Michigan fish species, including *A. fulvescens* (Hanshue and Harrington, 2011). As a result, *A. fulvescens* populations are restricted to the Grand River downstream of this structure. Annual spawning numbers of *A. fulvescens* are believed to be between 66 and 130 fish of primarily older adults (Hanshue and Harrington, 2011). Juvenile Lake Sturgeon have not been documented in the project area. Allowing Lake Sturgeon upstream of the 6th Street Dam and diversifying habitat in the Downstream Reach would improve conditions for A. fulvescens in the Grand River.

Moxostoma carinatum (river redhorse) – Threatened

Adults spawn each year, at temperatures between 18˚C and 24˚C (Mongeau et al., 1992; Jenkins and Burkhead, 1993), which occurs between mid-May through July in the Grand River.

Moxostoma carinatum occurs throughout the entire lower segment of the Grand River, from downstream of the Maple River near Lyons to Grand Haven near the mouth of Lake Michigan (Hanshue and Harrington, 2011). Small numbers of River Redhorse have been found in the project area during summer electrofishing surveys (Holtgren, personal communication). River Redhorse are known to occupy areas with deep runs, swift currents, and larger substrates during Winter and Spring months and then shift to lower velocities and finer substrates during Summer and Fall months. The diversity of habitat, with coarser substrate and a wider variability of localized flow velocities, will increase and subsequently provide a habitat mosaic with improved conditions for River Redhorse.

Lyon Edge Project (Construction, HP8-8RNS-2WDK2):

This project is not anticipated to have any impacts on wildlife and habitat. All project work is occurring above the ordinary high water mark (OHWM) or behind the floodwall. No work or construction access will occur within the Grand River and a debris net will be installed under work area to prevent debris from adversely impacting aquatic wildlife, including aquatic macroinvertebrate habitat, fish passage, or fish habitat. USFWS Consistency letter dated May 4, 2022 indicates “no effect” for federally protected Snuffbox Mussel *(Epioblasma triquetra).*

Review of Michigan Natural Features Inventory (MNFI) notes the following state protected aquatic wildlife exist within 1.5 miles of the project area: Snuff box *(Epioblasma triquetra),* Purple wartyback *(Cyclonaias)*, River redhorse *(Moxostoma carinatum)*, Slippershell *(Alasmidonta viridis)*, Black sandshell *(Ligumia recta)*, Fawnsfoot *(Truncilla donaciformis)*. Proposed work activities will not impact these species as no work is proposed within the Grand River.

East River Edge Project (Campau) (Construction, HP8-PWB2-465KA):

The East River Edge sidewalk improvement project is expected to have a positive impact on wildlife. The project is proposed to install slabs of dolomitic limestone and native vegetative plugs along the river edge to reduce streambank erosion and create streamside habitat foraging, resting, and breeding areas. The project will reduce streambank erosion which will also benefit the aquatic wildlife downstream of the project area. Proposed work extends 2.75 feet waterward of the OHWM and will be conducted entirely from upland area using a turbidity curtain.

Review of Michigan Natural Features Inventory (MNFI) notes the following state protected aquatic wildlife exist within 1.5 miles of the project area: Snuff box *(Epioblasma triquetra),* Purple wartyback *(Cyclonaias)*, River redhorse *(Moxostoma carinatum)*, Slippershell *(Alasmidonta viridis)*, Black sandshell *(Ligumia recta)*, Fawnsfoot *(Truncilla donaciformis)*. It is anticipated that work activities will likely not impact these species as their presence was not identified in the 2020 mussel survey conducted by EcoAnalysts. USFWS Consistency letter dated April 8, 2021 indicates “no effect” for federally protected Snuffbox Mussel.

USFWS has also indicated the 2020 mussel survey conducted by EcoAnalysts would be acceptable for this project and was submitted with the permit application. EcoAnalysts confirmed that common mussels were found in the project area (email correspondence attached). Early

coordination with MDNR Biologist notes 2 state protected mussels (Snuffbox and Black sandshell) species may be in the project reach. As requested by EGLE, further coordination with MDNR and the City to address potential impacts to protected aquatic species has been requested, has not occurred, and will be handled during permit review process.

This project is not anticipated to have an adverse impact on fish passage. The dolomitic limestone and native vegetative plugs will provide a stable natural river edge which will have a positive impact on macroinvertebrates and fish habitat due to reduced sediment load from erosion. Streamside vegetation will provide safe harbor areas and cooler water temperatures for aquatic species, including macroinvertebrates and larval and juvenile fish species. Furthermore, the proposed work is not installing structures that would typically interfere with fish passage (e.g., weir, dam, etc.)

Grand Rapids Public Museum Riverfront Improvements (Construction, HPD-8EMK-1EGF2):
The Grand Rapids Public Museum riverfront project is expected to have no adverse impacts on wildlife. The current large riprap offers little habitat value. Replacing the existing riprap with either natural field stone or dolomitic limestone would not change that habitat value, and the disturbance on the stream bottom is 0.01 acre.

Native plantings along channel banks will work to improve streamside foraging, resting, and breeding areas for terrestrial wildlife. Work will be conducted from upland areas and steel sheeting cofferdam will be used to protect existing undergrade structures during the construction process, so no tracking in the river is currently proposed. Work is anticipated to extend approximately 0.5-1.0 feet past the water's edge but would not extend into the limits of the 890 cfs line. Therefore, this project would result in no impacts to mussel habitat areas. The dolomitic limestone and native vegetative plugs will provide a stable natural river edge that will have a positive impact on macroinvertebrates and fish habitat due to reduced sediment load from erosion. Streamside vegetation will provide resting areas and refugia, and cooler water temperatures which will benefit aquatic species. Furthermore, proposed work is not installing structures that would significantly modify conditions that would interfere with fish passage (e.g., weir, dam, etc.)

USFWS Consistency letter dated November 16, 2021 (attached) indicates "no effect" for federally protected Snuffbox Mussel). Review of Michigan Natural Features Inventory (MNFI) (attached) notes the following state protected aquatic wildlife exist within 1.5 miles of the project area: Snuff box *(Epioblasma triquetra),* Purple wartyback *(Cyclonaias)*, River redhorse *(Moxostoma carinatum)*, Slippershell *(Alasmidonta viridis)*, Black sandshell *(Ligumia recta)*, Fawnsfoot *(Truncilla donaciformis)*. Impacts from proposed work activities will be negligible given work extends minimally (1 foot) into the water.

Leonard St. to Ann St. Trail (Construction, WRP040128 v. 1):
Inquiry to MNFI (attached) notes 3 state Threatened Species (Purple Wartyback, Slippershell and River Red Horse), and 2 state Endangered Species (Black Sand Shell and Peregrine Falcon), may exist within 1 mile of the project area. No adverse impact to Peregrine Falcon or River Red Horse is expected to occur as a result of proposed activities. Peregrine Falcon preferred habitat (inland or coastal cliffs, open woodlands near water, and potentially high city buildings) generally does not exist in the project area. River Red Horse habitat is associated

with long deep runs (1-10 feet) in rivers, and proposed work activities will not extend into these areas of the Grand River. Mussels and/or their habitat will not be impacted as proposed activities do not impact the channel bed.

Evaluation of federally protected species was conducted using USFWS IPaC determination key for the following species: Whooping Crane, Snuffbox Mussel, Karner Blue and Monarch Butterfly, Eastern Massasauga, and Indiana, Northern Long Eared and Tricolored bats. Based on absence of suitable habitat, urbanized area, and existing site conditions, it was determined no impacts to these species would occur as a result of proposed work activities. There is reasonable assumption no impact to mussels will occur as all work will occur from upland area and no activities will impact the riverbed.

Furthermore, all work activities will occur outside the 890 CFS line and not impact mussels or their habitat. Mussel studies for the Grand River note the 890 CFS is the breakpoint line for where mussels live and thrive, therefore no adverse impact to either federal or state protected mussels is anticipated to occur.

Coldbrook Water Pump Stations – RFA #3 (Master Plan only):
This site is currently a parking lot and storage buildings with a concrete floodwall along the river edge. No threatened and endangered species would be anticipated in the upland portion of this project. Threatened and endangered mussels could possibly be in the river near this area.

There is an assumed possible 0.03 acre of permanent streambed impact for the emergency access boat ramp. This would reduce the potential habitat for mussels in the river. A temporary streambed impact of 0.06 acres (243 m^2) was assumed to be needed for construction, including the 0.03 acre area mentioned above. The anticipated population of mussel in this area, assuming a mussel density of 1.7/m^2, would be approximately 420 mussels in this area. Assuming approximately 80% of the unionids would be translocated; the estimated take for this project is 85 mussels based on the current concept design. Measures that would be used to mitigate impacts include translocating mussels from the construction area to a suitable recipient site.

Fish Ladder Park – RFA #5 (Master Plan only):
This site is currently a park along the river edge. No threatened and endangered species would be anticipated in the upland portion of this project. Threatened and endangered mussels could possibly be in the river near this area.

This park may be one access point for the Corps project. Any river edge work included in this plan may be in conjunction with that project. This project is estimated to have up to 0.45 acre (1820 m^2) in areas of the river that could be occupied by mussels. Total permanent streambed impact area is estimated to be 0.08 acres. Assuming the higher 1.7/m^2 density of mussels upstream of 6th St. dam (rather than 0.3/m^2 downstream of the dam) in order to be conservative, the streambed impacts could include approximately 3,100 mussels. Therefore, assuming 80% of the mussels can be translocated, the take is assumed to be 620 mussels. The total impact to the mussels may be duplicated since both the Corps Project and the Fish Ladder Park project may account for the same riverbed area in the impact assessment.

There are some trees in this park, which could potentially be bat habitat, although it is unlikely as the area is already heavily urbanized. As a precaution, trees should be removed from

construction/staging areas in winter months to avoid effects on roosting bats or evaluated for bat habitat prior to removal. No threatened and endangered species would be anticipated in the upland portion of this project.

Wealthy St. Access (Concept Design):
The parcels along the river edge are currently underutilized parking areas with minimal facilities to the river. There are some trees in the area, but any potential impacts to threatened or endangered bats would be avoided or minimized. No threatened and endangered species would be anticipated in the upland portion of this project.

Threatened and endangered mussels could possibly be in the river near this area. A mussel survey has not been completed for this area. Within the 0.30 acre (1215 m^2) of temporary streambed impact and no permanent streambed impact area, the anticipated population of mussels, using mussel density of 0.1/m^2, there would be approximately 120 mussels in this area. Approximately 80% of the unionids within the cofferdams would be translocated; therefore, take estimates for mussels associated with his project have been calculated to be approximately 25 mussels.

Measures that would be used to mitigate impacts include translocating mussels from the construction area to a suitable recipient site.

201 Market Ave. (Permitting HPZ-0BP4-6TQCH):
The June 6, 2023 inquiry to MNFI for the Canal Park and Ah-Nab-Awen projects was determined appropriate to use for this project, given the project site is within close proximity to the two other sites and has similar work activities being proposed. MNFI notes 3 state Threatened Species (Purple Wartyback, Slippershell and River Red Horse), and 2 state Endangered Species (Black Sand Shell and Peregrine Falcon), may exist within 1 mile of the project area. No adverse impact to Peregrine Falcon is expected to occur as a result of proposed activities. Peregrine Falcon preferred habitat (inland or coastal cliffs, open woodlands near water, and potentially high city buildings) generally does not exist in the project area. River Red Horse habitat is associated with long deep runs (1-10 feet) in rivers, and proposed work activities will not extend into these areas of the Grand River. Lastly, protected mussels and/or their habitat will not be impacted as proposed activities do not impact the channel bed, and work will be conducted from upland area.

Evaluation of federally protected species was conducted using USFWS IPaC determination key for the following species: Whooping Crane, Snuffbox Mussel, Karner Blue and Monarch Butterfly, Eastern Massasauga (EMR), and Indiana, Northern Long Eared (NLB) and Tricolored bats. USFWS Consistency letter dated November 20, 2023 notes no effect for all species except EMR and NLB, which have a not likely to adversely affect (NLAA) designation. Based on absence of suitable habitat, urbanized area, existing site conditions, and construction methodology, it was determined no adverse impacts to these species would occur as a result of proposed work activities.

Furthermore, all work activities will occur outside the 890 CFS line and not impact mussels or their habitat. Mussel studies for the Grand River Revitalization project (HNV-A018-7X9N3) note the 890 CFS is the breakpoint line for where mussels live and thrive, therefore no adverse impact to either federal or state protected mussels is anticipated to occur. Tree removals will occur

during the migrating season (October to March 30) to ensure no adverse impact to federally protected bats.

Fishbeck has determined there is reasonable certainty of no take for Snuffbox or Northern Long Eared bat for the following reasons:

- All work will occur from upland area and no equipment will enter the water.
- All work will occur outside the 890 CFS lines, which is breakpoint line for where mussels live and thrive.
- Turbidity curtain will be used in areas where work occurs below the OHWM to prevent off-site siltation to the greatest extent possible. Curtains will be installed from upland area or by wading out into the river.
- Silt fence or coir logs will be used to prevent off-site siltation in work areas above the OHWM.
- All SESC measures will be inspected and maintained daily throughout construction and any deficiencies observed will be repaired prior to commencement of daily activities.
- No work will impact the river bed.
- Tree removals will occur during the migratory season.

Canal Park (Construction, WRP040025 V.1):
Inquiry to MNFI (attached) notes 3 state Threatened Species (Purple Wartyback, Slippershell and River Red Horse), and 2 state Endangered Species (Black Sand Shell and Peregrine Falcon), may exist within 1 mile of the project area. No adverse impact to Peregrine Falcon or River Red Horse is expected to occur as a result of proposed activities. Peregrine Falcon preferred habitat (inland or coastal cliffs, open woodlands near water, and potentially high city buildings) generally does not exist in the project area. River Red Horse habitat is associated with long deep runs (1-10 feet) in rivers, and proposed work activities will not extend into these areas of the Grand River. Mussels and/or their habitat will not be impacted as proposed activities do not impact the channel bed.

Evaluation of federally protected species was conducted using USFWS IPaC determination key for the following species: Whooping Crane, Snuffbox Mussel, Karner Blue and Monarch Butterfly, Eastern Massasauga, and Indiana, Northern Long Eared and Tricolored bats. Based on absence of suitable habitat, urbanized area, and existing site conditions, it was determined no impacts to these species would occur as a result of proposed work activities. There is reasonable assumption no impact to mussels will occur as all work will occur from upland area and no activities will impact the riverbed.

Furthermore, all work activities will occur outside the 890 CFS line and not impact mussels or their habitat. Mussel studies for the Grand River note the 890 CFS is the breakpoint line for where mussels live and thrive, therefore no adverse impact to either federal or state protected mussels is anticipated to occur.

6th St. Park (Concept Design):
This project is anticipated to not adversely impact wildlife and habitat. This park may be one of the access points for the Corps project. Any river edge work included in this plan may be in conjunction with that project. This project is estimated to have up to 1 acre (4046 m^2) in

streambed impacts, which would include approximately 7,000 mussels assuming a 1.7/m^2 density, but the mussels could be translocated. Assuming 80% of the mussels would be translocated, the take is estimated to be 1,400 mussels. The total impact to the mussels in this assessment may be duplicated since the Corps project include the same riverbed area in the impact assessment.

Since the park as it exists today is a dilapidated parking lot, and the proposed improvements will include increased vegetation, it is anticipated to have positive impacts on wildlife and habitat.

There are some trees in this park, which could potentially be bat habitat, although it is unlikely as the area is already heavily urbanized. As a precaution, trees should be removed from construction/staging areas in winter months to avoid effects on roosting bats or evaluated for bat habitat prior to removal. No threatened and endangered species would be anticipated in the upland portion of this project.

Riverside Park (Master Plan only):
This park provides a variety of habitat for wildlife, including some common aquatic wildlife. Envisioned work will be assumed to improve water quality of the lagoons and stormwater runoff and increase wetlands, wet meadows, and upland plantings. For the purpose of this assessment, it was assumed there would be 1.0 acres (4046 m^2) of temporary riverbed impact area that impacted mussels, including 0.5 acres of permanent streambed impact. Assuming a 3.0/m^2 density, this project would impact approximately 12,200 mussels. The mussels would be translocated. Assuming 80% of the mussels would be translocated, the take is estimated to be 2,440 mussels.

Habitat assessments for the northern long-eared bat, Indiana bat, and the karner blue butterfly may be necessary at the time design starts. As a precaution, trees should be removed from construction/staging areas in winter months to avoid effects on roosting bats or evaluated for bat habitat prior to removal. No threatened and endangered species would be anticipated in the upland portion of this project.

Given the current wide variety and habitat, and the goal of adding other natural features, it is anticipated that any impacts to wildlife will be temporary from construction, and the long term impacts is anticipated to be positive. No permanent adverse impacts are anticipated.

Ah-Nab-Awen Park - South (Active Design)
There are no impacts on wildlife and habitat, including threatened and endangered species.

Impacts on Wetlands

Lower Reach Project (Permitting, HQ2-Y2FM-WS9TA):
The Lower Reach Project has been designed to avoid and minimize impacts to wetlands. Temporary impacts have been minimized to 0.01 acres, which would be protected in the field during this impact. Permanent impacts have been minimized to 0.01 acres, which would be replanted following completion of the project.

Corps Project including RFA#2 (Concept Design):
The Corps project may have a direct impact on 0.21 acres of wetlands, as determined from the 2014 Golder Wetland Delineation, which identified a total of 3.09 acres of wetlands along the Grand River from approximately Ann St. to Fulton St. This area of wetland impact includes the area of the elevated boardwalk included in RFA #2, the Water Department Storage Yard. More recent delineation data from the 2019 Fishbeck report was also referenced but does not extend upstream of 6th Street Dam. Wetland impact associated with the Corps project could potentially be reduced based on updated wetlands delineation, further discussion on construction methodology, and/or further design development from the 30% design state.

The changes in water levels relative to existing conditions are expected to have indirect impacts to existing wetlands and other riparian areas within the project reach. Water levels in areas downstream of 6th Street Dam would increase, while water levels in areas between the dam and the AHS would decrease. These changes in water levels would alter the frequency of inundation of existing wetlands and are anticipated to result in some changes to long-term wetland boundaries. Much of the vegetation within the delineated wetlands are well-established non-emergent species; these portions of wetlands would continue to be periodically inundated and remain vegetated similar to existing conditions. Since non-emergent species of wetland vegetation do not rely as much on specific water levels in the river, much of the existing vegetation is expected to survive and/or adjust to the new water level. Specific estimation of indirect impacts to wetlands resulting from the proposed changes to water levels are unable to be approximated at this time. There appears to be some emergent wetland vegetation within the 1.7 acre delineated wetland on the east bank directly upstream of Leonard Street. These emergent species of vegetation are anticipated to be impacted by lower water levels; however, the new inundation patterns of post-project conditions would likely establish new, and potentially expanded areas of emergent wetlands.

Lyon Edge Project (Construction, HP8-8RNS-2WDK2):
There are no anticipated wetlands impacts for the Lyon Edge Project. All work is upland above the OHWM.

East River Edge Project (Campau) (Construction, HP8-PWB2-465KA):
There are no anticipated wetland impacts for the East River Edge sidewalk improvement project. There are no wetlands in this project area.

Grand Rapids Public Museum Riverfront Improvements (Construction, HPD-8EMK-1EGF2):
There are no anticipated wetland impacts from the Grand Rapids Public Museum Riverfront project. There are no wetlands in this project area.

Leonard St. to Ann St. Trail (Construction, WRP040128 v. 1):
No wetlands are anticipated to be impacted by this project.

Coldbrook Water Pump Stations – RFA #3 (Master Plan only):
There are no known adverse impacts to wetlands in this project. This area was not included in any of the project wetland delineations, and the State's online wetland mapper shows no wetland in this area. River for All conceptual plans for the Coldbrook Decommissioned Water Pumping Station Site imagines a stormwater outfall water quality treatment area, which could be beneficial to wetlands.

Fish Ladder Park – RFA #5 (Master Plan only):
River for All plans for the Fish Ladder Park redevelopment could result in temporary disturbance of portions of the 0.25 acres of wetland along the RDB between the 6th Street Dam and I-196 as identified in 2014 Golder wetland delineation report. Permanent impacts are not anticipated based on this delineation. The wetlands delineations would be updated prior to any future design, and any impacts would be avoided, minimized, or mitigated to the extent possible.

Wealthy St. Access (Concept Design):
We are not currently aware of any detailed wetland delineation on this site, so the State of Michigan's online wetland mapper was utilized. From this mapper, it appears a forested wetland up to approximately 0.15 acres is on the eastern river edge site. A wetland delineation would have to be performed on this concept prior to future design. Any impacts to the wetland would be avoided, minimized, or mitigated.

201 Market Ave. (Permitting HPZ-0BP4-6TQCH):
A wetlands delineation was performed in July 2023. The wetland in the project area consisted of ten segments with an approximate total area of 0.95-acre. De minimus impacts to wetlands area, totaling 0.09 acres, will result from the proposed work. This project will result in improved ecological resources along the river's edge due to the naturalization of the shoreline. Proposed native vegetation will improve water quality and facilitate streamside aquatic habitat and foraging areas do not currently exist.

Canal Park (Construction, WRP040025 V.1):
There are no anticipated wetlands impacts for the Canal Park Project. There are no wetlands in this project area.

6th St. Park (Concept Design): From the 2014 Golder Wetland Delineation, there was 0.05 acres of wetland just north of 6th St. dam. These wetlands may be temporarily impacted by construction, but proper best management practices to protect, avoid, or minimize the impacts would be utilized. River for All conceptual plans for portions of this site along the left descending bank just north of the I-196 westbound bridge include the creation of two small marsh-type wetland features, which would lead to a beneficial impact.

Riverside Park (Master Plan only):
A wetland delineation has not yet been performed for this site. Based on the State's online wetland mapper, there could be 50-60 acres of wetland in the park, including the area of the lagoons. The goals of the project include to improve the lagoons, wetlands, wet meadows, and upland plantings. To achieve this goal, it may be necessary to impact wetlands in the park, but

these adverse impacts are assumed to be temporary, and permanent impacts would be positive. No permanent adverse impacts to the wetlands are anticipated. A wetland delineation will be performed prior to finalizing design. Temporary impacts due to construction may occur, but proper best management practices may be installed.

Ah-Nab-Awen Park - South (Active Design)
There are no anticipated wetlands impacts for this project. There are no wetlands in this project area.

Impacts on Stream Function

Lower Reach Project (Permitting, HQ2-Y2FM-WS9TA):

Hydrology:
The project would not impact the hydrology of the river.

Hydraulics:
The proposed removal the four low-head dams and installation of the proposed substrate enhancements would replace a very uniformly flowing and hydraulically disconnected reach with a more dynamic and diverse hydraulic environment that more-closely emulates a natural river. The stream gradient distributed at the dams would be spread-out over the project reach, both over the proposed grade control structures and over the existing channel bed. Average flow velocities throughout the reach would generally increase as energy dissipation is spread out. More diversity in flow depths and velocities, as well as substrate, would result from the project and riffles, glides, pools, and runs would exist that do not under existing conditions.

Geomorphology:
The geomorphology of the reach may see positive change. The woody debris that collects on the low-head dams would collect in more natural ways on proposed substrate enhancements or native channel bed. Sediment would transport through the reach similar to existing conditions; localized transient sand deposition areas would be changed by the project but is still anticipated to flush from the reach during annual high flow events, similar to existing conditions. The post project conditions seek to encourage a dynamic equilibrium between hydraulics and substrate while maintaining stability and grade control within the reach.

Physicochemical:
Water temperatures are not anticipated to see notable change; however, dissolved oxygen levels may see slight improvements, resulting from increased hydraulic and substrate diversity.

Biological:
The biological health of the river is anticipated to gradually improve as a result of the project. Increased diversity in hydraulics and substrates provide areas of improved habitat for macro-invertebrates, benthic fish species, and mussels. The substrate enhancements and naturalized hydraulic function of the reach is also anticipated to have beneficial impacts to aquatic habitat diversity for resident fish communities.

Corps Project including RFA#2 (Concept Design):

Similar to the Lower Reach Project, the Corps project proposes significant changes to the existing stream function of the Grand River through the project reach. The proposed removal of 6th Street Dam and installation of the proposed in-river features seeks to replace a very uniformly flowing and hydraulically disconnected reach with a more dynamic and diverse hydraulic environment that more-closely emulates a natural river The stream gradient distributed at the dam would be spread-out over the project reach, both over the proposed features and over the existing channel bed. Average flow velocities throughout the reach would generally increase. Water levels would increase, when compared to existing conditions, downstream of the dam and decrease between the dam and the proposed AHS, establishing a more-gradual hydraulic gradient throughout the reach. More diversity in flow depths and velocities, as well as substrate,

would result from the project and riffles, glides, pools, and runs would exist that do not under existing conditions.

Lyon Edge Project (Construction, HP8-8RNS-2WDK2):
This project is not anticipated to have discernable impacts to the stream function of the Grand River.

East River Edge Project (Campau) (Construction, HP8-PWB2-465KA):
This project is not anticipated to have discernable impacts to the stream function of the Grand River.

Grand Rapids Public Museum Riverfront Improvements (Construction, HPD-8EMK-1EGF2):
This project is not anticipated to have discernable impacts to the stream function of the Grand River

Leonard St. to Ann St. Trail (Construction, WRP040128 v. 1):
This project is not anticipated to have discernable adverse impacts to the stream function of the Grand River.

Coldbrook Water Pump Stations – RFA #3 (Master Plan only):
This project is not anticipated to have discernable impacts to the stream function of the Grand River.

Fish Ladder Park – RFA #5 (Master Plan only):
This project is not anticipated to have discernable impacts to the stream function of the Grand River.

Wealthy St. Access (Concept Design):
This project is not anticipated to have discernable impacts to the stream function of the Grand River.

201 Market Ave. (Permitting HPZ-0BP4-6TQCH):
This project is not anticipated to have discernable impacts to the stream function of the Grand River.

Canal Park (Construction, WRP040025 V.1):
This project is not anticipated to have discernable impacts to the stream function of the Grand River.

6th St. Park (Concept Design):
This project is not anticipated to have discernable impacts to the stream function of the Grand River.

Riverside Park (Master Plan only):
If the lagoons are improved and wetlands are improved or added, there could be a positive impact on the stream function of the Grand River. None of the other improvements to this project would have discernable impacts to the stream function of the Grand River.

Ah-Nab-Awen Park - South (Active Design)
This project is not anticipated to have discernable impacts to the stream function of the Grand River.

Impacts on Modeled Flood Risk

Lower Reach Project (Permitting, HQ2-Y2FM-WS9TA):
This project has been hydraulically modelled and designed to maintain the City's freeboard deficient certification from FEMA. Localized increases in modeled flood stages occur within the project reach; however, the hydraulic evaluation of the project indicates that no harmful interference would result from the project. A CLOMR will be submitted to FEMA to fully address modeled increases in 100-yr flood levels.

Corps Project including RFA#2 (Concept Design):
The Corps Project has been added to the cumulative impacts model for the Lower Reach Project as requested by EGLE. The model calculates a no-rise condition during the 100-yr flood based on the 30% design of the proposed improvements. Localized increases in flood stages are modeled to occur at some locations within the project reach; however, all increases would be contained within the flood protections system and would not result in harmful interference.

Lyon Edge Project (Construction, HP8-8RNS-2WDK2):
Per the request from EGLE prior to Correction Request #3, all ancillary bank projects have been added to the HEC-RAS model for the Lower Reach Project; this includes the addition of the Lyon Edge Project. Model results indicate that no increases in modeled flood levels would occur from adding this project to the HEC-RAS model for the Project.

East River Edge Project (Campau) (Construction, HP8-PWB2-465KA):
Per the request from EGLE prior to Correction Request #3, all ancillary bank projects have been added to the HEC-RAS model for the Lower Reach Project; this includes the addition of the East River Edge Project. Model results indicate that no increases in modeled flood levels would occur from adding this project to the HEC-RAS model for the Project.

Grand Rapids Public Museum Riverfront Improvements (Construction, HPD-8EMK-1EGF2):
Per the request from EGLE prior to Correction Request #3, all ancillary bank projects have been added to the HEC-RAS model for the Lower Reach Project; this includes the addition of the Grand Rapids Public Museum Riverfront Improvements Project. Model results indicate that no increases in modeled flood levels would occur from adding this project to the HEC-RAS model for the Project.

Leonard St. to Ann St. Trail (Construction, WRP040128 v. 1):
This project has a net fill of 100 CY in the floodplain with no fill proposed to be under the OHWM. No changes to the modelled flood risk are anticipated.

Coldbrook Water Pump Stations – RFA #3 (Master Plan only):
This project has not progressed design far enough to have developed a hydraulic model to incorporate into the cumulative impacts HEC-RAS model for the Lower Reach Project. Based on the current estimate of earthwork quantities shown in Appendix B, this project would have a net cut within the floodplain; therefore, no adverse impacts to modeled flood risk are anticipated.

Fish Ladder Park – RFA #5 (Master Plan only):

This project has not progressed design far enough to have developed a hydraulic model to incorporate into the cumulative impacts HEC-RAS model for the Lower Reach Project. Based on the current estimate of earthwork quantities shown in Appendix B, this project would have a net cut below the OHWM and in the floodplain; therefore, no adverse impacts to modeled flood risk are anticipated.

Wealthy St. Access (Concept Design):
This project has not progressed design far enough to have developed a hydraulic model to incorporate into the cumulative impacts HEC-RAS model for the Lower Reach Project. Portions of this project may be designed to be within a conveyance shadow of the Wealthy St. bridge abutment and would be designed to have no impact on the base flood elevation. No adverse impacts to modelled flood risk are anticipated.

201 Market Ave. (Permitting HPZ-0BP4-6TQCH):
A hydraulic model for this project was created in HEC-RAS version 4.1. The project result in a slight decrease in Energy Grade Line or Hydraulic Grade Line throughout the project reach. Therefore, it is concluded the proposed project does not result in harmful interference.

Canal Park (Construction, WRP040025 V.1):
Based on the current estimate of earthwork quantities shown in Appendix B, this project would have a net cut below the OHWM and in the floodplain; therefore, no adverse impacts to modeled flood risk are anticipated.

6th St. Park (Concept Design):
This project has not progressed design far enough to have developed a hydraulic model to incorporate into the cumulative impacts HEC-RAS model for the Lower Reach Project. Based on the current estimate of earthwork quantities shown in Appendix B, this project would have a net cut below the OHWM and in the floodplain; therefore, no adverse impacts to modeled flood risk are anticipated.

Riverside Park (Master Plan only):
This project has not progressed design far enough to have developed a hydraulic model to incorporate into the cumulative impacts HEC-RAS model for the Lower Reach Project. The task of the design team is to build the project without causing an increase in the modeled flood levels.

Ah-Nab-Awen Park - South (Active Design)
This project has a dredge of 56 CY and fill of 128 CY which results in a net fill of 72 CY in the floodplain with no fill proposed to be under the OHWM. No changes to the modelled flood risk are anticipated.

Temporary Construction Impacts

Lower Reach Project (Permitting, HQ2-Y2FM-WS9TA):
This project team has evaluated construction means and methods to avoid and minimize construction impact to the environment. Disturbance from construction equipment (noise, equipment, traffic, vibration) may temporarily cause aquatic wildlife to flee from the nearshore area. However, it is anticipated species will return when construction is complete. Temporary turbidity during construction would be managed with industry standards best management practices including turbidity curtains.

Corps Project including RFA#2 (Concept Design):
Similar to the discussion of construction means and methods for the Lower Reach Project, temporary impacts during construction for this project would also evaluate alternative means and methods for construction to minimize and avoid impacts to aquatic resources. A discussion of temporary construction impacts to aquatic wildlife and threatened and endangered species for the Corps project has been included in the earlier section on Impacts to Wildlife and Habitat. Assumed construction impact was included in the assessments of the mussels. Temporary construction impacts to fish passage are minimal and would be similar to that of the Lower Reach project. It is worth noting that because the 6th St dam is currently a barrier to many species of fish in the Grand River, temporary adverse impacts to fish passage (relative to existing conditions) would be minimal. Disturbance from construction equipment (noise, equipment, traffic, vibration) may temporarily cause aquatic wildlife to flee from the nearshore area. However, it is anticipated species will return when construction is complete. Temporary turbidity during construction would be managed with industry standards and assumed to be performed in a similar fashion to means and methods proposed in the Lower Reach Project.

Lyon Edge Project (Construction, HP8-8RNS-2WDK2):
There are no construction impacts to the riverbed, shoreline or other water features as no work is proposed within the river and floodwall exists throughout entire project area. All work will occur from upland areas and no equipment will enter the river. Approximately 200 lineal feet of temporary construction debris net will be stretched under the work platform to ensure no construction debris enters the river. It is not anticipated that shade from the debris net will adversely impact aquatic resources. Proposed work activities will permanently reduce cover over bottom land by 367 square feet. It is anticipated that aquatic biota and insects will not be adversely impacted by temporary construction netting or increased sunlight. Disturbance from construction equipment (noise, equipment, traffic, vibration) may temporarily cause aquatic wildlife to flee from the nearshore area. However, it is anticipated species will return when construction is complete.

East River Edge Project (Campau) (Construction, HP8-PWB2-465KA):
All construction activities will occur from upland area and no heavy equipment will enter the water. A turbidity curtain will be placed sufficient to cover the entire project area during construction. Construction activities will permanently impact 360 lineal feet of shoreline. Approximately 288 square feet of riverbed will be impacted. Riverbed impacts will extend no greater than 2.75 lineal feet into water from edge of shoreline. Disturbance from construction equipment (noise, equipment, traffic, vibration) may temporarily cause aquatic wildlife to flee

from the nearshore area. However, it is anticipated species will return when construction is complete.

Grand Rapids Public Museum Riverfront Improvements (Construction, HPD-8EMK-1EGF2):
The majority of construction activities will occur from upland areas and no heavy equipment will enter the water. 500 lineal feet of temporary sheet piling will be installed approximately +/-1 foot east of water's edge at 3500 CFS. Approximately 500 square feet of riverbed will be impacted. Temporary sheeting is necessary to protect existing channel bank and undergrade structures during the construction process. Impacts to the riverbed, aquatic wildlife and organisms during construction will be negligible. Disturbances from construction equipment (noise, equipment, traffic, vibration, etc.) may temporarily cause aquatic wildlife to flee from the nearshore area, however, it is anticipated species will return when construction is complete.

Leonard St. to Ann St. Trail (Construction, WRP040128 v. 1):
Temporary construction impacts are anticipated to be minimal. All work will occur upland and will not be performed during high flow events. Disturbances from construction equipment (noise, equipment, traffic, vibration, etc.) may temporarily cause wildlife to flee from the area, however, it is anticipated species will return when construction is complete.

Coldbrook Water Pump Stations – RFA #3 (Master Plan only):
Since this project is only at conceptual design stage, the project design still needs significant development prior to developing a construction plan. For the sake of this cumulative impact assessment, several assumptions will be made to satisfy EGLE's request. However, these assumptions will be refined as the project develops.

The assumptions are discussed in the sections on impact to wildlife and habitat and turbidity above. The assumed impacts would be minimized using best management practices. There are no other anticipated constructions impacts at this time.

Fish Ladder Park – RFA #5 (Master Plan only):
Since this project is only at conceptual design stage, the project design still needs significant development prior to developing a construction plan. For the sake of this cumulative impact assessment, several assumptions will be made to satisfy EGLE's request. However, these assumptions will be refined as the project develops.

The assumptions are discussed in the sections on impact to wildlife and habitat and turbidity above. The assumed impacts would be minimized using best management practices. There are no other anticipated constructions impacts at this time.

Wealthy St. Access (Concept Design):
Since this project is only at conceptual design stage, the project design still needs significant development prior to developing a construction plan. For the sake of this cumulative impact assessment, several assumptions will be made to satisfy EGLE's request. However, these assumptions will be refined as the project develops.

The assumptions are discussed in the sections on impact to wildlife and habitat and turbidity above. The assumed temporary impacts would be minimized using best management practices. There are no other anticipated constructions impacts at this time.

201 Market Ave. (Permitting HPZ-0BP4-6TQCH):
Most of the construction of this project will take place in upland areas. Some work below the OHWM is needed in order to construct the base of the retaining wall or sea wall as well as to remove existing debris and plant vegetation. Prior to any work occurring, appropriate best management practices such as a turbidity curtain would be installed to limit any potential turbidity that arose from the project. The project will also schedule the work under the OHWM during periods of typical low flows on the Grand River.

Canal Park (Construction, WRP040025 V.1):
The construction is assumed to take place from the river edge and no work will occur from the riverbed. Appropriate best management practices such as turbidity curtain would be installed to limit any potential turbidity that arose from the project.

6th St. Park (Concept Design):
Since this project is only at conceptual design stage, the project design still needs significant development prior to developing a construction plan. For the sake of this cumulative impact assessment, several assumptions will be made to satisfy EGLE's request. However, these assumptions will be refined as the project develops.

The assumptions are discussed in the sections on impact to wildlife and habitat and turbidity above. The assumed impacts would be minimized using best management practices. There are no other anticipated constructions impacts at this time.

Riverside Park (Master Plan only):
Since this project is only at conceptual design stage, the project design still needs significant development prior to developing a construction plan. For the sake of this cumulative impact assessment, several assumptions will be made to satisfy EGLE's request. However, these assumptions will be refined as the project develops.

Any work along the river edge would take place from land. Appropriate best management practices such as turbidity curtain would be installed to limit any potential turbidity that arose from the project.

Ah-Nab-Awen Park - South (Active Design)
There are no construction impacts to the riverbed, shoreline or other water features as no work is proposed within the river or below the OHWM. All work will occur from upland areas and will not be any closer than 80' from the river's edge. Between the proposed work and river includes existing lawn and landscape beds. A silt fence barrier will be placed and maintained throughout the duration of construction to prevent any silt from entering the river.

OPPORTUNITY SITE #2

DECOMMISSIONED WATER DEPARTMENT STORAGE YARD SITE

SCHEMATIC DESIGN PLAN

This site will be decommissioned as a storage yard for the City of Grand Rapids Water Department and is re-envisioned as a riverfront park. When the rapids are restored and an adjustable hydraulic structure is added, boat passage and river access will dramatically transform this site into a regional activity hub. Design plans call for:

1. **An elevated canopy trail** to connect pedestrians to the forested canopy and protect habitat areas.
2. **Protected ceremonial fire rings** for Anishinaabe and Great River Bands of Ottawa Indian use.
2b. **Public-use outdoor fire pits** Activate the plaza in the winter
3. **A winter lodge** for year-round educational and cultural events.
4. **A repurposed water storage tank** provides a unique space for large events and daily use.
5. **A log-jam inspired nature playground** ensures this park will provide on-land destination recreation for users of all ages.
6. **A dedicated drop-off area** can accommodate large group access and circulating river traffic.
7. **The mid-level terrace** provides a flexible, multi-use lawn area closer to the water.
8. **River terraces** provide additional access to the water's edge for anglers, tubers, and waders.
9. **Small gathering overlooks** allow friends, family and fans to watch boaters from the river's edge.

Integrated Grand River restoration improvements:

10. Adjustable hydraulic structure (AHS)
11. AHS maintenance and control building
12. Boat passage

OPPORTUNITY SITE #3

COLDBROOK DECOMMISSIONED WATER PUMPING STATION SITE

SCHEMATIC DESIGN PLAN

This site is unique because Coldbrook Creek historically outfalled to the Grand River at this location, but was buried in a pipe as part of industrial development. This is an opportunity to divert a portion of the creek into a low-flow channel and open up the outfall for natural, visible stormwater treatment. Following the Grand River restoration, this site will be a critical hub for river access.

(1) **The mid-block crossing and low-trail connection** links this site to the larger River Trail network.

(2) **Stepped river access** connects to the trail and can potentially be used for commercial boat launches and fishing access.

(3) **Existing overlook** to remain.

(4a) **Diversion and surfacing of a portion of Coldbrook Creek** demonstrates the channel's historic alignment.

(4b) **Water quality treatment area at the outfall** treats stormwater before it enters the Grand River.

(5) **A reinforced earth/green wall** softens the corridor.

(6) **A sculptural play area** connects learning and play.

(7) **A repurposed water department building** is planned for public use, and may include relocation of the Parks and Recreation offices, recreation fitness classes, and river-centric event spaces.

(8) **Flexible plaza spaces** adjacent to the building provide areas for outdoor learning and events. Cultural activities, such as canoe building with the Anishinaabe and programmed outdoor recreation activities should be pursued here.

(9) **Mixed use redevelopment** is anticipated at the corner of Leonard Street and North Monroe Avenue with plazas oriented towards the river.

(10) **A large multipurpose lawn** provides flexible space with an option for future bus drop off and trailers transporting tubers and kayakers to the site.

(11) **ADA and small parking lot** is located onsite.

(12) **An emergency boat-access ramp**, placed in coordination with the ongoing Grand River restoration planning.

(13) **Proposed overlook** complements existing design.

NOT TO SCALE

IMPLEMENTATION PLAN AND RIVER DESIGN GUIDELINES

FINAL DESIGN RECOMMENDATIONS

FISH LADDER PARK

SCHEMATIC DESIGN PLAN

Fish Ladder Park has been identified as an important community gathering spot and the structure is an iconic piece of functional art. Following removal of the 6th Street Dam, the Fish Ladder structure will be modified to continue to provide fish passage, and the surrounding park will become a the primary destination for whitewater competition spectators, as well as a hub for boaters and fishing access.

1. **An upper-falls trail deck** is located in the existing tree canopy north of the Fish Ladder.
2. **The existing fish ladder structure** will remain for rapids viewing and fish observation.
3. **The existing pump station** is operated by City Environmental Services and will remain onsite.
4. **A small changing room, restroom, and fish cleaning station** provide services for river users and screen the pump station maintenance court.
5. **A flexible plaza and adjacent parking area** can accommodate small seasonal farmers' markets or other events.
6. **A series of picnic groves** are located near the parking lot to provide shaded seating.
7. **A sloped event lawn next to new trees** that are planted on the high point of the existing berm to provide shade.
8. **An overlook deck** screens an existing outfall.
9. **River seating terraces** allow viewing and lounging at the water's edge.
10. **Emergency boat ramp** provides river access.
11. **Upper viewing perches** on the embankment link Scribner Avenue to Fish Ladder Park, provide small lounging pockets, and expand spectator areas.
12. **A high-water trail connection** and stepped walkway creates a critical year-round trail connection for the west bank of the Grand River.
13. **Angling and wading access steps** link the River Trail to the bank below the rapids.

NOT TO SCALE

Dear Mr. Carey:

MATERIALS TESTING CONSULTANTS, INC. has completed a preliminary geotechnical engineering study related to the proposed modifications to the Grand River based on our understanding of the project as indicated in the *Grand River Rapids Restoration Preferred Alternative Plan Set* dated April 5, 2015. Results of the study are presented in the attached report.

We appreciate this opportunity to provide engineering services to you. Please contact our office should have any questions or require further assistance.

Sincerely,

MATERIALS TESTING CONSULTANTS, INC.

REPORT OF PRELIMINARY GEOTECHNICAL STUDY
GRAND RIVER RAPIDS RESTORATION

1.0 INTRODUCTION

Grand Rapids Whitewater has retained RiverRestoration to provide engineering and restoration planning services associated with the proposed modifications to the Grand River. RiverRestoration has retained Materials Testing Consultants, Inc. (MTC) to perform a preliminary geotechnical study for the proposed river modifications. Descriptions of the study methods and results are provided herein. This work has been performed as described in our proposal dated January 29, 2015.

The scope of this study includes the following:

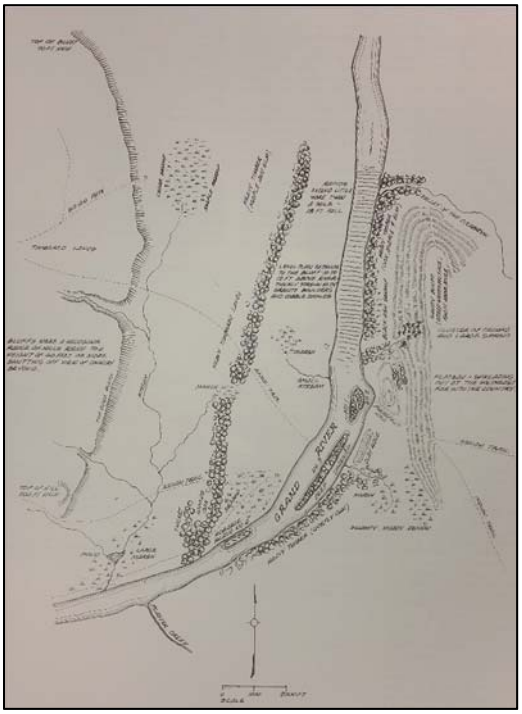
- Task 1 - Information gathering and review of available existing information, including:
    - Research of available boring logs from MDOT and the City of Grand Rapids for bridges that cross the Grand River;
    - Compile prior boring logs compiled from our recent study of the stability of the existing floodwalls and embankments; and
    - Review of documentation available for the existing Powers Gypsum Mine, which was located partially under the Grand River north of Fulton Street near the existing pedestrian bridge.
- Task 2 - Perform preliminary geotechnical analyses for proposed river modification structures, including:
    - Riverside Park Berm
        - Provide recommendations for berm geometry and materials and evaluate berm stability.
    - Adjustable Crest Hydraulic Structure and Fish Passage Structure
        - Evaluate foundation options for support of proposed structures;
        - Provide foundation constructability considerations (bedrock excavation and rock anchors);
        - Evaluate acceptable slope angles for adjacent riverbank; and
        - Evaluate Seepage/piping below proposed fish passage structure and barrier structure.

        - Evaluate report of past geotechnical concerns at MDOT office building on Front Street adjacent to proposed barrier structure and evaluate need for cutoff wall.
    - Floodwall modifications
        - Evaluate stability impact of proposed river modifications to existing floodwall system; and
        - Provide recommendations for naturalized levee.
    - 6th Street Dam and Beautification Dam Removal
        - Provide preliminary geotechnical recommendations for removal.
- Task 3 - Preparation of this report.

Presented herein are descriptions of background information pertaining to the study, the proposed river modifications, the investigation methodology, investigation results, and our preliminary conclusions and engineering recommendations. A study area plan (Figure 1) and boring location plans (Figures 2 through 14) are attached as well as stability analysis results (Appendices A and B) and mine research documentation (Appendix C) to support this report.

1.1 Background Information

The Grand Rapids area was first settled by Europeans near the start of the 19th century by missionaries and fur traders alongside the Ottawa Indians who had developed several villages along the banks of the Grand River. The Northwest Territory survey reached Grand Rapids in 1831, setting the boundaries for Kent County and leading to the incorporation of Grand Rapids as a village in 1838. A map of Grand Rapids prior to incorporation as a village was prepared by E.C. Swanson from survey records made between 1831 and 1837. The map describes rapids within the Grand River extending over one mile in length with a total fall of approximately 18 ft.



Grand Rapids was incorporated as a city in 1850 and continued to develop adjacent to the Grand River as the population grew, utilizing the river for transportation of raw materials and manufactured items, drinking water, sewage disposal and personal transportation. Beginning in the 1830's, canals were constructed along the west and east banks of the river to generate power for mills and factories.

In 1866, the 6th Street Dam (located at the alignment of 4th Street) was constructed to further harness the river's power. The west and east canals have since been backfilled, however, the 6th Street Dam remains as can be seen in the picture at left.

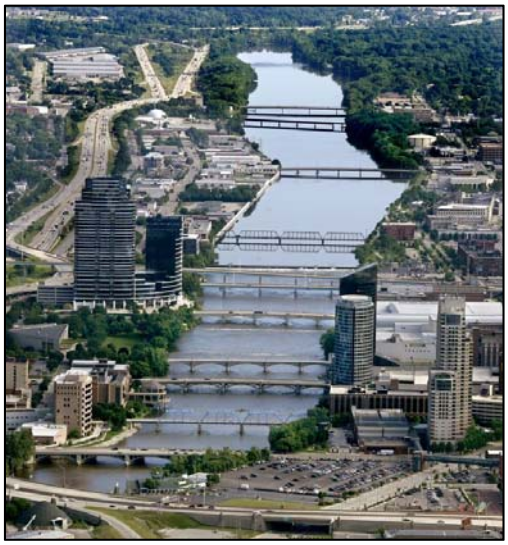
As growth and development continued along the banks of the river, flooding became more and more problematic, prompting the construction of a flood protection system. The Grand River flood protection system was constructed through numerous initiatives dating back to the late 1800's, however, significant momentum towards the completion of the system occurred only after demands from the public following the "Great Flood" of 1904 and subsequent flood events in 1905 and 1907.

Flooding in the spring of 1904 due to a sudden spring thaw combined with heavy rains resulted in river levels rising to over 5 ft above flood stage (20. 4 ft peak), over $1 million in property damage and flooding which extended as far as John Ball Park. Construction of the original floodwall system was completed in 1911.

Numerous modifications and improvements have been made on both private and public properties since the original construction was completed. Floodwalls include gravity walls, cantilever walls, counterfort walls, hybrid retaining walls containing properties of several wall types in addition to a combination trunk sewer-floodwall. A majority of the floodwalls were constructed using concrete, however, several of the gravity walls utilized stone and mortar construction methods as was popular in the late 1800's and early 1900's. The picture below shows construction of the cobble and mortar gravity floodwall located immediately north of the Pearl Street Bridge in front of the current Amway Grand Plaza Hotel.

Modifications to the river since 1911 were not limited to floodwalls, as is evident from the presence of four beautification dams, located downstream of the 6th Street Dam, constructed in 1927 with the goal of maintaining a constant river level throughout downtown. By 1960, the former west side and east side power canals had been backfilled to create development property and parking space, however, the 6th Street Dam and beautification dams remain.

In 1974, a concrete fish ladder was constructed along the west side of the 6th Street Dam to aid spawning fish intent on swimming upstream of the 6th Street Dam. Modifications to the existing flood protection system are ongoing as a result of continued development adjacent to the river as well as freeboard requirements based on revised FEMA Base Flood Elevations (BFE). The Grand River flowing through modern downtown Grand Rapids is pictured to the right viewed from the south.



1.2 Proposed River Modifications

The current study constitutes an approximately 3.6 mile length of the Grand River from Riverside Park (north extent) to the Fulton Street Bridge (south extent). Modifications and additions to the existing Grand River are proposed in an effort to increase recreational use of the Grand River as well as restore and enhance the river to a more natural condition complete with rapids after the namesake of the City. A summary of proposed modifications is provided below:

- Construction of a new earth berm within Riverside Park
- Construction of an adjustable crest hydraulic structure and fish passage between Leonard Street Bridge and Ann Street Bridge
- Boat ramp construction between 6th Street Bridge and Leonard Street Bridge
- Access ramp construction north of I-196 Bridge
- Removal of the five existing dam structures (6th Street Dam and beautification dams)
- River bottom grading south of the 6th Street Dam
- Construction of miscellaneous proposed river structures

Construction of a new earth berm near Station 2310+00 is proposed within Riverside Park to provide control of flows less than 19,000 cfs for the area. The proposed berm will have an approximate length of 2500 ft with a proposed top of berm elevation at el 611 requiring the placement of approximately 1 to 3 ft of additional fill. The proposed berm will be completely submerged with water levels above the 10-year event. It should be noted that elevations provided within this report are based upon the NAVD88 datum.

Avoiding and minimizing impacts with the removal of the 6th Street Dam necessitates a means to control Grand River water levels during high and low water flow events as well as to control the migration of invasive species upstream. An adjustable crest hydraulic structure and accompanying fish passage will be constructed between Stations 2211+00 and 2217+00 to avoid and minimize impacts.

A new emergency access boat ramp (Station 2187+00) is proposed between the Leonard Street Bridge and the 6th Street Bridge along the east bank of the river. The boat ramp will be approximately 120 ft long and constructed utilizing a 6-inch reinforced concrete slab with 1.5 to 2 ft deep turned-down slab edges.

The 6th Street Dam and accompanying 4 beautification dam structures will be removed as part of construction and various river channel modifications will be performed south of the existing 6th Street Dam including river bottom grading, placement of gravel, cobble and boulder and wave block construction. Proposed river grading will require cuts up to 6 ft deep and fill placement up to 8 ft high creating pools, riffles and rapids through downtown Grand Rapids from the 6th Street Dam to Fulton Street. Wading crossing downstream of the 6th Street Dam and slabstone steps upstream of the dam will provide access to river features.

A new pedestrian access ramp (Station 2153+00) is proposed along the east riverbank between the 6th Street Dam and the I-196 Bridge. The new ramp will require removal of the existing floodwall as well as retaining wall construction to support existing grades north and south of the proposed ramp. Other proposed river structures include pre-cast channel markers and wading crossings. Details for a concrete accessible platform supported by 20-inch concrete piers were also included in the project plans to be constructed at the end of the ramp.

2.0 INVESTIGATION METHODOLOGY

Information gathering and review of available information were included in Task 1 which included relevant boring logs and geotechnical reports completed near the current study area as well as historical drawings for projects completed near the river including flood protection, bridge construction and utility placement projects. A majority of the subsurface information was obtained from company archive files with supplementary information obtained from City of Grand Rapids and Michigan Department of Transportation (MDOT) archives. In total, approximately 650 borings logs from soil borings performed within the City limits adjacent to the Grand River were reviewed dating back to 1921. Location plans of the borings are attached as Figures B-2 through B-14.

Geotechnical reports reviewed as part of this project included a 2012 geotechnical study performed by MTC for Fishbeck, Thompson, Carr & Huber (FTCH) whereby the stability of the existing Grand River flood protection system was evaluated according to Federal Regulation (44CFR65.10). Development of the 2010 FEMA base flood model for the Grand River in Grand Rapids resulted in a general increase in the FEMA Base Flood Elevation within the City limits. As a result of the increase, several areas of existing flood protection no longer met freeboard requirements above the revised 2010 BFE per the reference Federal Regulation which prompted the 2012 study. The information gathered during the 2012 study provided a foundation of data which was both utilized and expanded upon for the current study.

Historical drawings were obtained from Mr. Mark Garvey of the City of Grand Rapids and Mr. Joseph Platte, P.E. of FTCH. Historical drawings provided relevant information pertaining to the design and construction of various structures within the study area including floodwalls and embankments dating back to the early 1900's, vehicular bridges between Ann Street Bridge and Wealthy Street Bridge and utility placement adjacent to and below the Grand River. Subsurface information obtained from boring logs performed for bridge piers and abutments was frequently provided on historic bridge plan sheets including the soil strata type and thickness and depth to bedrock if encountered. The bearing elevations of bridge foundations (bottom of piles, bottom of pier/abutment footings) were frequently provided on the individual bridge boring logs.

Gypsum mining, once a major industry in Grand Rapids, began in 1841 with an open quarry and mill on Plaster Creek near the Grand River. As demand for gypsum products evolved from soil fertilizer to plaster and stucco applications, additional mines were developed within the area including the Powers Mine which operated on the west bank of the Grand River between Fulton Street and Pearl Street. Past projects including the Grand Valley State University Eberhard Center and the Grand Rapids Public Museum constructed near the former underground Powers Mine required research into the mine's location and an understanding of the potential impact of the former mine on the proposed construction. Pertinent available information was obtained from Grand Rapids Public Museum and Public Library archives in addition to various government agencies including the Michigan Department of Natural Resources Geological Survey Division, the United States Bureau of Mining, the DOW Mine Map Repository and the office of Mine Safety and Health Administration. Results of our research are discussed in Section 3.2 with historical documentation related to the Powers Mine included in Appendix C.

3.0 INVESTIGATION RESULTS

3.1 Regional Geology

The *Map of the Surface Formations of the Southern Peninsula of Michigan*, published by the State of Michigan, indicates the site is in an area of glacial outwash. The Grand River valley is known to have been a major channel of glacial water flows. Near-surface soil conditions typically are found to be primarily granular with numerous cobbles and boulders, erratics from a distant geologic source. Several areas along the west and east riverbanks are known to have been low-lying areas prior to development of the area and have been filled with a variety of uncontrolled urban fill materials. Some fill material may have originated from dredging the main channel.

Relatively shallow bedrock is present throughout the study area which includes a limestone and sandstone cap of the Bayport Formation from the north end of the study area to the approximate Lyon Street alignment where the Bayport Formation ends and the underlying weathered shale and gypsum of the Michigan Formation continues south below the overburden soil. The top of the Bayport Limestone is exposed at the riverbed at the site of the fish ladder and 6th Street Dam and floodwall drawings in the vicinity indicate bearing directly on bedrock. In the vicinity of Pearl Street and south where the Bayport Limestone is absent the Michigan Formation Shale is approximately 10 to 30 ft below the alluvial riverbed.

3.2 Subsurface Conditions

During the development of the area during the late 1800's and early 1900's, placement of available miscellaneous material was common to raise low-lying riverbank levels, to create additional property for development as well as flood protection for nearby residences and businesses, defining what is now the current river boundary. A majority of the existing riverbanks are therefore composed of miscellaneous fill material extending to depths up to 20 or 30 ft depth.

The miscellaneous fill material is composed of a highly variable assortment of granular and cohesive soil, boulder and cobble (primarily granite erratics), organic material (topsoil, peat and wood), building debris, cinders, brick and the like. Directly adjacent to and within the river channel, granular glacial outwash and post-glacial alluvium are present below the miscellaneous fill material below which relatively shallow bedrock is present as previously discussed. Native cohesive soil is also encountered adjacent to and within the river channel most often in the form of highly weathered shale above more competent shale. A summary of subsurface conditions described at various bridges crossing the Grand River within the study area is provided below including the approximate depth to bedrock and bedrock type.

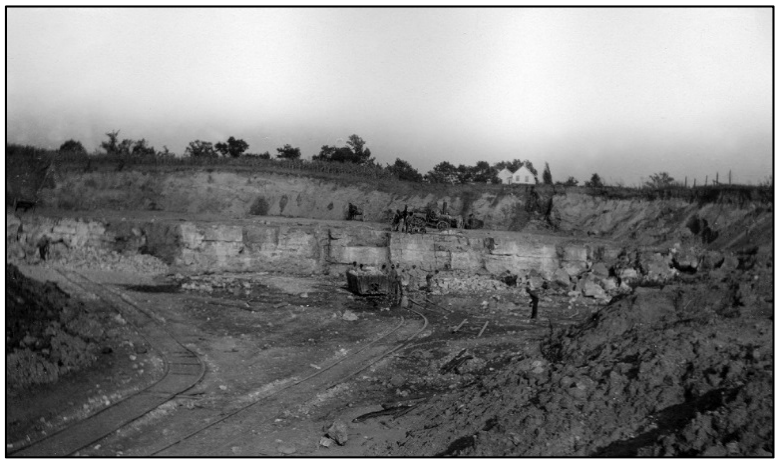
Table 3.2.1 - General Subsurface Conditions Encountered at Bridge Structures

Bridge Structure	Overburden Soil	Bedrock Type	Bedrock Depth (ft)
Ann Street	Granular	Limestone	> 60
Leonard Street	Granular	Limestone	1 to 7
Sixth Street	Granular	Limestone	1 to 2
I-196	Granular	Limestone	2 to 3
Bridge Street	Granular	Limestone	3 to 11
Gillett Bridge	Granular	Shale and Gypsum	20 to 30
Pearl Street	Granular	Gypsum and Shale	26 to 30
Blue Bridge	Granular	Gypsum and Shale	10 to 15
Fulton Street	Granular	Shale with Limestone	26 to 30
Wealthy Street	Granular	Shale	7 to 9

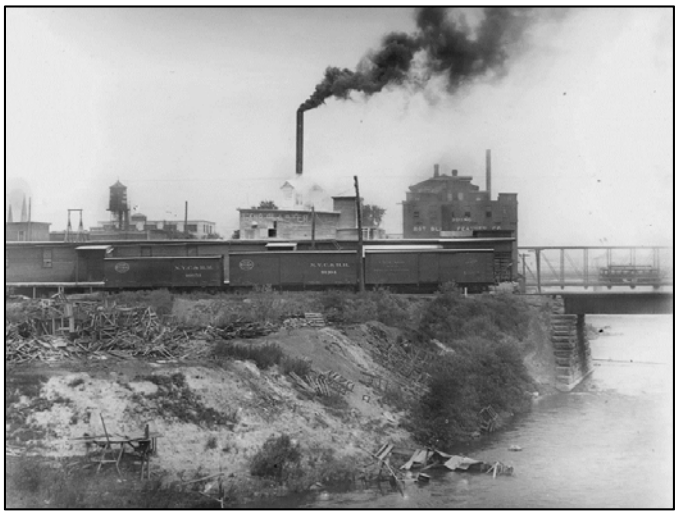
Note: Bedrock depth provided is approximate and is measured from bottom of river.

Historical documents indicating the foundation-type and bedrock depth at the Gillett and Blue Bridges were not found during our research. Bedrock information provided in Table 3.2.1 for the Gillett and Blue Bridges is based on soil borings performed near these structures.

3.3 Mine Research



Gypsum mining formerly located near the study area include the Plaster Creek Quarry, located southwest of the project limits (pictured below) and the Powers Mine located within the south end of the project. The presence of surface beds of gypsum near Plaster Creek allowed for the formation of an open quarry and corresponding mill around the mid-1800's which remained in operation until the early 1900's. Subsequent development of the area has resulted in filling of the former quarry.



Available information concerning the Powers Mine indicates the shaft to the mine began in 1896 by Mr. William T. Powers. Mr. Powers organized the Gypsum Products Manufacturing Company in 1896 prior to construction of the 12 ft by 12 ft mine shaft to mine a 12 ft thick layer of gypsum located approximately 60 ft below the riverbed with a total shaft depth of approximately 85 ft. Approximate mining limits were obtained from *The Gypsum of Michigan and The Plaster Industry*, Volume IX, Part II, 1904. Records indicate that a mill was constructed directly above the mine shaft. Historical photographs and city directories place the mill at the northwest corner of the existing Blue Bridge west abutment (former Grand Rapids & Indiana Railroad Bridge). The picture at right shows the top of the former mill structure directly north of the Blue Bridge on the west bank of the Grand River.

A room-and-pillar style mining operation was utilized consisting of rooms 50 ft square and pillars 20 ft square. The mine was in operation from approximately 1896 to 1911. A fire in 1903 caused a temporary shutdown in the mining. It is not known when the mill was re-opened, however, records indicate that gypsum was mined at least during 1908 to 1911. The roof of the mine contained numerous faults and seams which allowed significant amounts of water to infiltrate the mine necessitating groundwater pumping upwards of 150 gallons per minute to create suitable working conditions.

Records indicate the Gypsum Products Manufacturing Company owned up to approximately 8 acres of property during this time, mostly under the Grand River with 75 percent of the gypsum removed from approximately one acre, mostly below the Grand River's west bank. After the founding of the Company, the land was sold to various entities until in 1910, the extent of the property owned by the Company consisted of a small parcel containing the mill structure and underlying mine shaft. The Company still retained the rights to mine below the entire original parcel.

Following Mr. Powers death in 1910, the mine was succeeded to his son-in-law, Mr. J.W. Spooner, who stated in 1911 that the mine was on too small a scale to be profitable and intended to shut the mining operation down in the coming year. Records indicate that the mine only ran approximately 25 percent of the time between 1896 and 1911. The Company was dissolved in 1914 with property and rights associated with the mining operation sold to the railroad. It not expected that the railroad continued mining at the site following acquisition of the mine property.

Based on the existing site topography and no indication of significant ground subsidence in the area, it is expected that the mine shaft was closed and filled and the underground mine rooms allowed to fill with water. A 1955 letter from a Grand Rapids Public Museum Employee stated that the mine was filled in some time after it was closed. Additional information regarding the closure and possible filling of the mine could not be found. The estimated limits of the mining and mining rights are shown on Figure 3 based on information from a 1907 survey and 1911 tax assessor.

MTC has performed soil borings directly south and north of the Blue Bridge on the west bank of the Grand River for the GVSU Eberhard Center Project and for the Grand Rapids Public Museum Project with no indication of a mine shaft or void within bedrock encountered to depths up to 82 ft below the former ground surface at the boring locations. The boring information obtained by MTC to-date within this area lends further evidence to historical information describing the mines location, footprint and impact below ground. The impact of prior mining activity on the proposed river modifications is discussed in Section 4.6.

3.4 Floodwall and Embankment Stability

A total of 6 cross section locations within non-natural ground segments of the study area were selected to evaluate floodwall and embankment stability with respect to existing conditions as well as conditions associated with the proposed river modifications. Sections were selected where subsurface conditions and floodwall/embankment geometries were well established allowing for an accurate assessment of both existing and proposed stability. Section locations are shown on Figure 1.

Section locations are labeled with a "W" or "E" to designate the west or east riverbank, respectively. Of the 6 section locations, 2 include floodwall protections while 4 include non-natural embankment flood protection. Table 3.4.1 provides a summary of the location and flood protection type at the stability sections.

Table 3.4.1 –Section Summary

Section No.	Address	Flood Protection Type
1W	220 Front Ave SW	Embankment
2W	750 Front Ave NW	Gravity Floodwall
2E	905 Monroe Ave NW	Embankment
3W	1300 Front Ave NW	Gravity / Cantilever Floodwall
3E	1529 Monroe Ave NW	Embankment
4E	60 Ann St NW	Embankment

Stability and seepage requirements for embankments and foundations are provided in the U.S. Army Corps of Engineers (COE) Manual "Design and Construction of Levees" (EM 1110-2-1913), Chapter 6, Section 2 which provides required factors of safety associated with specific loading cases. The loading cases and the corresponding required factors of safety are provided in Table 3.4.2

Table 3.4.2 – Loading Cases and Corresponding Required Factors of Safety

Case	Loading Description	Required Factor of Safety
Case I	Existing Condition	1.3
Case II	Sudden Drawdown	1.0 to 1.2
Case III	Steady State Seepage (BFE)	1.4
Case IV	Earthquake	See Discussion Below

For Case I loading, effective stress parameters are utilized for both granular and cohesive soils while for Case II, III and IV loading, total stress parameters were used for cohesive soil to reflect the shear strength of the soil under short-term loading conditions. Base flood elevations, required for analysis of Case II and Case III loading, were provided by Mr. Joseph Platte, P.E. of FTCH in an email received on April 6, 2015 which are based upon the 2010 FEMA base flood model.

ER 1110-2-1806 is referenced by EM 1110-2-1913 for earthquake design and evaluation. Although no specific factor of safety is provided in the reference regarding earthquake loading, the reference states that the project "team is responsible for establishing the earthquake engineering requirements for the project, planning and executing the seismological and engineering investigations, and evaluating the results." The reference also describes that detailed site explorations, site-specific ground motion studies, and structural analyses are not necessary for projects located in Zones 0 and 1 and that preliminary values of the ground motions obtained from published seismic zone maps may be used to determine if seismic loadings control the design and to set the scope of any proposed site specific studies. The study area is in Zone 0 with a very low risk for seismic activity and, therefore, it is considered that a detailed site exploration and determination of site-specific ground motions will not be necessary and a pseudostatic analysis will be sufficient.

The pseudostatic method is an inertial analysis method originally applied by Terzaghi (1950) where the cyclic nature of the earthquake is ignored and the earthquake loading is applied as an additional static force acting through the centroid of the mass under consideration. The horizontal pseudostatic force (F_h) acts to decrease stability while the vertical pseudostatic force (F_v) typically has less impact on stability and is frequently neglected. The horizontal pseudostatic force acting upon the mass is equal to the product of the total weight of the mass (W) and the horizontal pseudostatic coefficient (k_h) where k_h is equal to the maximum horizontal acceleration (a_{max}) divided by the acceleration due to gravity (g).

Per Kramer (*Geotechnical Earthquake Engineering*, Prentice Hall, 1996), pseudostatic coefficients used in practice generally correspond to acceleration values well below a_{max} because the body of mass is typically not rigid and the peak acceleration occurs only for a very short time period. Kramer references a study performed by Hynes-Griffin and Franklin (1984) which concluded that earth dams with pseudostatic factors of safety greater than 1.0 using $k_h = 0.5a_{max}/g$ should not develop "dangerously large" deformations.

Conservatively, the peak ground acceleration (PGA) can be selected for a_{max} if the maximum horizontal acceleration is unknown. United States Geological Survey (USGS) 2008 Earthquake Hazard Maps of the Central/Eastern United States were used to select a PGA for the study area corresponding to an earthquake with a 10 percent probability of exceedance in 50 years (CEUS

PGA 10%/50 years, 2008). A PGA of 2% g (0.02g) was selected. The PGA associated with 2 percent probability of exceedance in 50 years in the study area is also very near 2% g. The pseudostatic coefficient was then computed as follows:

$$k_h = 0.5 \times \frac{a_{max}}{g} = 0.5 \times \frac{0.02g}{g} = 0.01 .$$

Therefore, significant deformations are not anticipated when using a horizontal pseudostatic coefficient of 0.01 and where static stability safety factors are greater than 1.0.

Computer software SLIDE 6.0 was utilized to perform limit equilibrium slope stability and finite element steady state seepage analyses (where appropriate) at the section locations. The Modified Bishop Method was utilized to compute the factor of safety against slope stability failure for the four loading cases considered. In addition to global stability for section locations with walls, factors of safety associated with sliding and overturning failure were estimated. Floodwalls are generally bearing upon and keyed into bedrock, therefore, bearing considerations were deemed unnecessary.

Steady state seepage analyses were performed for embankment sections to evaluate seepage behind embankments (seepage flow perpendicular to riverbank) as well as the potential for the formation of seepage faces. Due to floodwalls bearing upon bedrock, seepage below floodwalls is not expected to be a concern and was not analyzed. Although some seepage faces were predicted to develop on the landside of the embankments due to seepage flow perpendicular to the riverbank during steady state base flood conditions, the predicted hydraulic gradient was substantially less (15 to 20 percent) compared to the critical hydraulic gradient necessary to initiate piping or heave at the estimated seepage discharge point. Steady state seepage concerns are not expected to be exacerbated by the proposed river modifications.

The Adjustable Crest Hydraulic Structure will create a hydraulic head on the order of 8 ft (el 610 to 602) and a damming effect with river elevations slightly higher (several feet) on the upstream side (el 610) of the hydraulic structure and slightly lower (several feet) on the downstream side (el 602) when compared to existing ordinary high water elevations. The presence of the floodwall on the west bank and the concrete retaining wall on the east back, both possibly founded upon and

keyed into bedrock, are expected to significantly restrict seepage flow perpendicular to river flow. The presence of floodwall approximately 500 ft upstream of the hydraulic structure along the west bank is expected to result in a longshore hydraulic gradient less than the critical hydraulic gradient of retained soil behind the floodwalls, thus, effectively controlling seepage below the west riverbank. A seepage cutoff wall west of the west floodwall to control the hydraulic gradient below the west riverbank is not expected to be necessary. Longshore seepage below the east riverbank will be controlled through design measures associated with the proposed fish passage and slope reconstruction.

Settlement is generally not applicable to our study as the potential and magnitude for future settlement is negligible because settlement associated with construction has already occurred given the age of the flood protection system (100 years ±). Proposed modifications to the system may result in low water elevations several feet below current levels, however, the increase in effective stress from potential lower water elevations is not expected to result in significant amounts of settlement. Some settlement below the proposed Riverside Park berm may occur as result of fill placement, however, additional soil borings will be required to accurately evaluate the magnitude of differential settlement along the berm. Settlement of foundation soils below the berm fill can be accommodated for through the placement of additional fill during construction.

4.0 CONCLUSIONS AND RECOMMENDATIONS

The available information suggests the Grand River originally (prior to City's development in the mid 1800's) dropped 18 ft in elevation in a distance of a little more than one mile. This region of the "Grand Rapids" extended from the approximate current alignment of Leonard Street southward to approximately the current Gillette Bridge. We suspect the Grand River throughout much of the rapids was flowing upon or very near the top of bedrock surface of the Bayport Limestone Formation. It is expected that numerous boulders and cobbles were present in the region of the rapids as glacial outwash flows would have deposited such erratics. Although several feet of variation is noted, the top of bedrock at Leonard Street is approximately el 600 while at Michigan Street it is approximately el 590. Floodwalls, bridges and the 6th Street Dam throughout this area are largely founded on bedrock.

The gravity sections of boulder floodwalls north and south of Pearl Street are believed to have been constructed with primarily granite boulders pulled from the river and are founded at the river bottom with very little embedment or scour protection.

Soil behind the floodwalls and along the Grand River embankments is primarily miscellaneous fill over shallow bedrock throughout the region of former rapids and miscellaneous fill over post-glacial alluvium both north and south of the former rapids.

4.1 Proposed Riverside Park Berm

Additional control of overbanking flows will be provided by the construction of an approximately 2500 ft long earth berm along the east bank of the Grand River in Riverside Park. Existing grades in the area of the proposed berm range from el 608 to 610 with a proposed top of berm elevation at 611. The placement of approximately 1 to 3 ft of engineered fill will, therefore, be required to construct the proposed earth berm.

A picture of Riverside Park viewed from the north where the proposed berm will be constructed is shown at right. Past soil borings performed in the area for the completed Riverside Trail Project encountered several feet of very loose sand fill and soft sandy clay fill with variable amounts of organic material overlying loose to medium dense granular soil. This material is expected to be suitable for as subgrade for berm construction following appropriate site and subgrade preparation.

The limits of the proposed berm area should be prepared initially through clearing and grubbing followed by topsoil stripping. The limits of the proposed construction area, prior to the placement fill material, should be proof-rolled by the contractor. Proof-rolling is defined as the passing of relatively heavy construction equipment over the soil subgrade under observation by the Geotechnical Engineer. The response of the soil, when subjected to the applied load, is subjectively evaluated by our staff with respect to its ability to support the overlying soil or structure. In areas where excessive deflection is observed, special subgrade preparation measures may be recommended to provide an acceptable subgrade condition. These measures may consist of compaction of the subgrade at moisture contents close to the optimum value, undercutting affected areas and replacing with engineered fill, use of a geotextile separation fabric or some combination of these measures.

The berm should be constructed through the placement of low permeability soil consisting of clayey sand (SC), lean clay (CL) or a combination thereof. The soil should be compacted in lifts not exceeding 9 inches in thickness to at least 95 percent of the maximum Standard Proctor dry density (ASTM D 698) with moisture contents during compaction within $\pm$2 percent of the soil's optimum moisture content. Sheepsfoot type compactors with a kneading form of compaction are typically found to be most effective in cohesive soil. The berm will be designed with overflow channels to equalize water pressure as a result of overtopping flows.

For preliminary design purposes, the berm should be constructed with maximum 1V:4H side slopes with a minimum top of berm width of 5 ft. The presence of a pedestrian path on top of the berm may necessitate a wider berm width. Considering the soil conditions encountered in nearby soil borings, excessive settlement associated with 3 ft of soil surcharge is not expected. Additional soil borings (at least 6 borings at 15 ft minimum depth) should be performed as part of final design phase services to evaluate the stability of the proposed earth berm and the seepage potential through the berm considering the design water surface elevations.

4.2 Proposed Adjustable Crest Hydraulic Structure and Fish Passage

The proposed Adjustable Crest Hydraulic Structure (ACHS) and accompanying fish passage will be constructed between Leonard Street and Ann Street, approximately 100 to 150 ft north of the existing Monroe Avenue water storage tank. Per Sheet D.08 of the preliminary project plans, three gate alternatives are under consideration supported by a concrete foundation bearing within the existing river channel. The fish passage will be constructed directly east of the hydraulic gate structure within the existing east bank slope and will consist of a terraced boulder wall on the east side of the passage and concrete walls on the west side of the passage. The passage is expected to be constructed of concrete and will contain five adjustable gates.

The existing west riverbank is supported by a counterfort and cantilever concrete floodwall bearing upon bedrock with a top of wall near el 617 and a bottom of foundation near el 597. The east riverbank contains a concrete retaining wall extending several feet above the ordinary water level with a vegetated soil slope extending from the top of the concrete wall up on an approximately 1V:2H slope to a walking path near el 620. Historical plans of the concrete retaining wall were not available from the City of Grand Rapids or FTCH, however, based on the observed wall geometry, historical building practices and the depth to bedrock, it is possible that the wall in question is founded upon bedrock. A soil boring performed northeast of the proposed structure near the east bank of the river encountered approximately 12 ft of granular fill containing varying amounts of debris and organic material overlying lean clay and peat to approximately 20 to 22 ft where limestone bedrock was encountered near el 598. The river channel bottom near the proposed hydraulic gate and fish passage structures varies from approximately els 600 to 602 and is expected to be composed of granular soil consisting of sand and gravel outwash overlying weathered limestone bedrock.

The proposed ACHS and fish passage are located near an active 46-inch transmission water main. As-built records from 1938 show the water main alignment extending due west from the former Monroe Avenue water treatment plant to the Grand River and crossing the river in a west-northwest direction to near the intersection of Front Avenue and Webster Street as shown on Figure 9. The water main is composed of reinforced concrete pipe with an invert elevation below the river near el 594. It is expected that a trench was excavated within the bedrock base in the river and the water main was placed directly in the trench during installation. Details regarding water main placement below the west floodwall are unknown including alignment, backfill, presence of bulkheads, etc. The approximate alignment of the 46-inch transmission water main, as shown on Figure 9, indicates an intersection between it and the proposed ACHS. The trench in the bedrock presents potential conduits of seepage pathways beneath the proposed structure. If an alternate location is not available, it will be necessary to investigate further the water transmission main and trench as well as potential seepage impacts and strategies to mitigate. The water main alignment has not been surveyed according to FTCH.

If an alternate location of the ACHS immediately north or south of the 46-inch transmission water main is selected, construction will likely require partial-width construction within the river channel and either bypassing of the river flow through placement of a temporary dam to create a controlled working environment for construction. Rock anchors are expected to be required for anchorage of the proposed ACHS with the structure keyed into the underlying limestone bedrock. Rock anchors may also be necessary for anchorage of the fish passage structure depending on the estimated lateral and uplift forces. For preliminary design, an anchor diameter of 4 inches, a minimum bond length of 8 ft into rock and center-to-center spacing of 7.5 ft an allowable uplift capacity of 28 kips may be used. The design loading upon the ACHS foundation as well as the condition and shear strength of the underlying bedrock will need to be understood in conjunction in order to estimate the number and depth of rock anchors required. Final design phase geotechnical services should include the performance of soil borings (at least 4 borings with rock coring to el 580) to evaluate the condition and strength properties of the bedrock.

The west side of the ACHS will connect into the existing floodwall adjacent to MDOT property. As part of Task 1 (information gathering), MDOT was contacted regarding whether or not any performance issues have occurred with the floodwall located on the east side of their property. We were informed by MDOT that no known settlement or movement issues are known. Excessive settlement and seepage below or west of the west floodwall associated with construction of the ACHS are not expected.

Considering the limited amount of design information available with respect to the proposed fish passage structure and based on the information provided, construction of the fish passage structure appears feasible. The presence of uncontrolled fill and organic soil (peat) creates stability concerns requiring probable overexcavation and replacement with engineered fill for proper support. Considering the foundation and slope influence region will likely be overexcavated and replaced with select engineered fill, a slope angle of 1V:3H may be used to satisfy USACE requirements for slope stability. Final design phase services should include the performance of soil borings (at least 5 borings to bedrock at estimated 20 ft depth) at the location of the proposed fish passage to evaluate these geotechnical risks.

The proposed ACHS and fish passage will likely both bear upon and be keyed into limestone bedrock. The seepage/piping associated with structures bearing seated within the bedrock is expected to be negligible.

It should be noted the concrete wall present at the toe of the east riverbank slope is in relatively poor condition based on a walkover survey of the area and observation of the exposed surfaces of the wall. The top and east side of the concrete wall as exposed during our site visit with a majority of the concrete surface experiencing severe cracking and spalling. It is expected this wall will need to be replaced where it is relied upon to support new structures or loads. The replacement wall section may consist of either a concrete gravity wall or a concrete cantilever wall founded upon and keyed into bedrock.

4.3 Impact to Existing Floodwalls and Embankments

A summary of the slope stability analyses performed at the 6 section locations for the four loading cases previously described is provided in Table 4.3.1. The geotechnical parameters considered at each section and the corresponding SLIDE output for each individual analysis are provided in Appendix A.

Table 4.3.1 – Slope Stability Analysis Summary

Section No.	Flood Protection Type	Loading Case	Minimum Global Factor of Safety	
			Existing Conditions	Proposed Conditions
1W	Embankment	Case I	3.42	3.43
		Case II	1.77	2.67
		Case III	3.42	3.95
		Case IV	3.42	3.72
2W	Gravity Floodwall	Case I	2.54	2.32
		Case II	2.03	1.62
		Case III	5.33	4.51
		Case IV	2.48	2.27
2E	Embankment	Case I	2.44	1.81
		Case II	1.90	1.39
		Case III	3.43	2.74
		Case IV	2.25	1.80
3W	Gravity / Cantilever Floodwall	Case I	2.32	2.26
		Case II	1.78	1.56
		Case III	4.98	4.78
		Case IV	2.27	2.21
3E	Embankment	Case I	2.45	2.71
		Case II	1.07	1.03
		Case III	2.49	2.41
		Case IV	2.33	2.57
4E	Embankment	Case I	1.40	1.30
		Case II	3.15	1.66
		Case III	5.91	2.10
		Case IV	3.54	2.15

Sections containing floodwall were evaluated for sliding and overturning stability for Case I (Existing Condition) and Case II (Sudden Drawdown) loading cases. Case III (Steady State Seepage) and Case IV (Earthquake) loading were not considered for floodwall sections due to (1) the hydrostatic pressure acting on the waterside of the floodwall will contribute to stability for Case III loading and (2) the earthquake loading influence is inconsequential as previously discussed considering Case IV loading. A summary of floodwall stability analyses is provided in Table 4.3.2. Floodwall stability calculations are provided in Appendix B.

Table 4.3.2 – Floodwall Stability Analysis Summary

Section No.	Floodwall Type	Loading Case	ΔH (ft) [1]	Overturning FS	Sliding FS	Eccentricity (ft)
2W	Gravity Wall	Case I: Existing OHW = 606.4	0	1.48	1.79	1.19
		Case I: Proposed OLW = 601.8	0	1.97	2.14	2.25
		Case II: Proposed	4.6	1.04	1.46	2.56
3W	Gravity / Cantilever Wall	Case I: Existing OHW = 607.0	0	3.28	2.09	-1.71
		Case I: Proposed OLW = 602.0	0	8.37	2.72	-1.38
		Case II: Proposed	9.0	1.11	1.11	3.00
		Case II: Proposed	11.1	0.77	0.93	6.03

1. Change in water head between landside and waterside
2. Cells highlighted in red indicate the controlling stability case (i.e. overturning vs. sliding)

Table 4.3.2 demonstrates the maximum allowable head differential during Case II loading to maintain a stable floodwall conditions. Although floodwalls within the Grand Rapids flood protection system do not appear to have been designed to resist loading strictly following Case II loading (total base flood retention with complete river drawdown), historically, the walls have withstood pressures resulting from drawdown after flood stage and provide a safety factor of at least 1.0. Although the walls become unstable with greater unbalanced water pressures, it is unrealistic to apply such parameters based on the successful past performance of the floodwalls and embankments.

Although the proposed modifications are expected to both positively and negatively affect the stability of floodwalls and embankments, factors of safety against embankment and foundation failure for both existing and proposed conditions are predicted to meet or exceed USACE requirements per EM 1110-2-1913.

As mentioned previously, steady state seepage through embankment sections and settlement due to proposed modifications is not expected to be a significant concern. Settlement computations were not performed given the duration of time which has passed since the original construction (100 ± years) and because anticipated modifications will not add substantial load to the structures.

The floodwalls at Pearl Street Bridge along the east bank of the river consist of cobble and mortar acting as a gravity mass to resist sliding and overturning forces from earth pressures and surcharge loads from both building loads and live loads. The walls extend approximately 170 ft north and 150 ft south of Pearl Street as shown on Figure 3 (approximately Stations 2129+80 to 2133+00). Sections of these floodwalls have been evaluated in the past as a result of both geotechnical and structural stability concerns and are known to have shallow embedment depths on the order of 1 to 2 ft below the existing river bottom with wall backfill consisting of uncontrolled soil and urban fill. River bottom grading resulting in soil removal and the corresponding removal of stabilizing passive soil resistance must be prevented in these areas. Additional scour protection should be included in the final design to prevent future scour adjacent to and below these structures.

4.4 Dam Removal

Partial-width construction techniques, temporary damming and the controlled lowering and discharge of retained water are expected to be required to remove the existing 6th Street Dam in order to avoid negatively impacting adjacent structures. It is suspected that construction of the beautification dams occurred after construction of the adjacent floodwalls. Considering this as well as the relatively small cross section of the beautification dams, beautification dam removal is not expected to pose a significant stability risk to adjacent structures.

Historical plans from 1926 indicate the 6th Street Dam has an approximate width of 17 ft, a total height on the order of 11 ft and a 2 ft embedment into bedrock with possible steel anchorage on the downstream end of the dam into bedrock. The dam was constructed utilizing a stone fill core with a concrete exterior. Historical plans for the beautification head dams indicate dam widths ranging from 4.3 ft to 5.8 ft with heights above the river bottom ranging from 1.5 ft to 3 ft with an embedment depth of 12 inches below the river bottom.

The 6th Street Dam extends continuously from the west riverbank to the east riverbank. On the west side of the river, the dam extends below the fish ladder which was constructed above the dam as shown in the picture at right (east fish ladder wall looking down at dam extending below ladder wall).

On the east side of the river, the 6th Street Dam intersects a pile-supported concrete floodwall and steel sheet pile floodwall on the east bank above which an overlook observation area is located. A picture of the east end of the dam and the east floodwall is shown at left (viewed from the south). In 2013, flooding of the Grand River resulted in undermining of the east bank floodwall immediately upstream and downstream of the 6th Street Dam necessitating steel sheet pile installation and grout fill placement within void areas below the overlook structure.

We envision two basic options for removal of the 6th Street Dam. One would involve complete removal including impacted structures at the east and west banks of the river. The other would involve leaving sections of the dam adjacent to the shore structures in place. More specifically, we expect the complete removal option would involve removal of the fish ladder structure on the west riverbank as well as the east floodwall structure supporting the previously-described observation area. Allowing the west and east extents of the dam to remain in-place option is expected to be less costly and involve integration with the on-shore structures in the river modification plan.

Removal of the 6th Street Dam will require a detailed demolition plan and schedule with contingency plans in-place should instability of adjacent structures be observed during demolition. The retained water surface should be lowered at a controlled rate no greater than 1 ft per 3 days to maintain stability of floodwalls and embankments. It should be noted we have not been retained to evaluate potential environmental risks associated with removal of the dams, including, but not limited to, sediment transport, localized scour or other issues within the study area.

If complete removal of the 6th Street Dam is selected, a minimum of two soil test borings with rock coring are recommended for design of new floodwall structures.

4.5 Miscellaneous Proposed Structures

Miscellaneous proposed structures associated with the project include the previously-described boat ramp, pedestrian access ramp, pre-cast wave blocks and channel markers, wading crossings and a concrete accessible platform. For on-shore structures, such as boat ramps and access ramps, overexcavation of the miscellaneous fill and replacement with compacted engineered fill is expected to be required. Overexcavation will likely be required to native alluvial deposits, the approximate depth of which should be evaluated through the performance of additional soil borings. For structures within the river, adequate embedment for scour protection and resistance to lateral loads are the primary concerns, recognizing that limestone bedrock is relatively close to the riverbed from approximately the location of the proposed Adjustable Crest Hydraulic Structure southward to approximately Gillette Bridge. Some rock excavation may be necessary to provide sufficient embedment and anchorage may be required.

The pedestrian access ramp will require removal of a section of the east floodwall located north of the I-196 Bridge structure. Retaining wall construction will be required north and south of the ramp to support ramp grades ranging from approximately el 600 at the river to el 615 at the east end of the ramp. Retaining wall design will need to consider all applicable surcharge loads which may act upon the walls including the adjacent I-196 Bridge embankment. Final design phase services should include the performance of soil borings (at least 4 borings to bedrock at estimated 20 ft depth) at the location of the proposed pedestrian access ramp.

4.6 Impact of Prior Mining Activity on Proposed River Modifications

There is no significant available evidence of ground subsidence or related settlement in the area of the former Powers Mine due to the prior mining activity in the early 1900's. Proposed river channel modifications in the vicinity of the former Powers Mine include the creation of pools requiring the excavation of approximately 1 to 2 ft. The proposed river modifications are not expected to impact the stability of the Powers Mine including sinkhole opportunities, mine roof collapse or solution activity of gypsum due to changing groundwater gradients in the vicinity of the mine. The former Plaster Creek Quarry is outside of the area of this project.

5.0 CLOSURE

In this report, descriptions of the background information pertaining to the study, the proposed river modification concept, the investigation methodology, investigation results and our preliminary conclusions and engineering recommendations have been provided. This effort does not imply or provide a guarantee or warranty of performance. We remain available to complete the remaining geotechnical investigation and evaluations necessary throughout the completion of this project. It is possible that hidden or latent conditions may be present and, should such conditions become evident, will require re-assessment or further investigation.

Lansing, Michigan

Dear Harry,

Enclosed is a map of greater Grand Rapids with all of the past and present gypsum operations marked on it. You are aware of the present ones, but here is the whole works as much as I know. Hope it will be of some use to you.

1. First gypsum quarry. Water filled, exposures along shore.
2. Abandoned Alabastine quarry. Water filled, exposures along shore.
3. Burned out Alabastine shaft.
4. Abandoned U.S. Gypsum Co. shaft. About 100 feet from road, no exposures.
5. Abandoned Pitsburgh Plate Glass Co. shaft. Now covered by small white pump building, no exposures.
6. Unidentified diggings. Remains of calcining kettles and scattered exposures. Opposite Jarecki Tool and Die Co. building. Follow railroad spur about 1000 feet. old Beverly Mine
7. Abandoned Powers Mine shaft. Under Grand River, now filled.
8. Grand Rapids Plaster Co.
9. Certain-Teed Products Co.

Not Marked

Grandville---Just east off Wilson Ave., a few blocks from M-21. A couple of old quarries, water filled and a few exposures although houses have been built around the edge.

Sincerely,

Mary Jane Dockeray

GYPSUM PRODUCTS MANUFACTURING COMPANY
J. W. Spooner, Gen. Mgr., 44 Powers TheatreBldg., Gd. Rap

This company owns about 8 acres on the west side of the river, mostly under the river, at the SE corner of Front and Pearl streets in the city of Grand Rapids.

There is a small mill on the property.

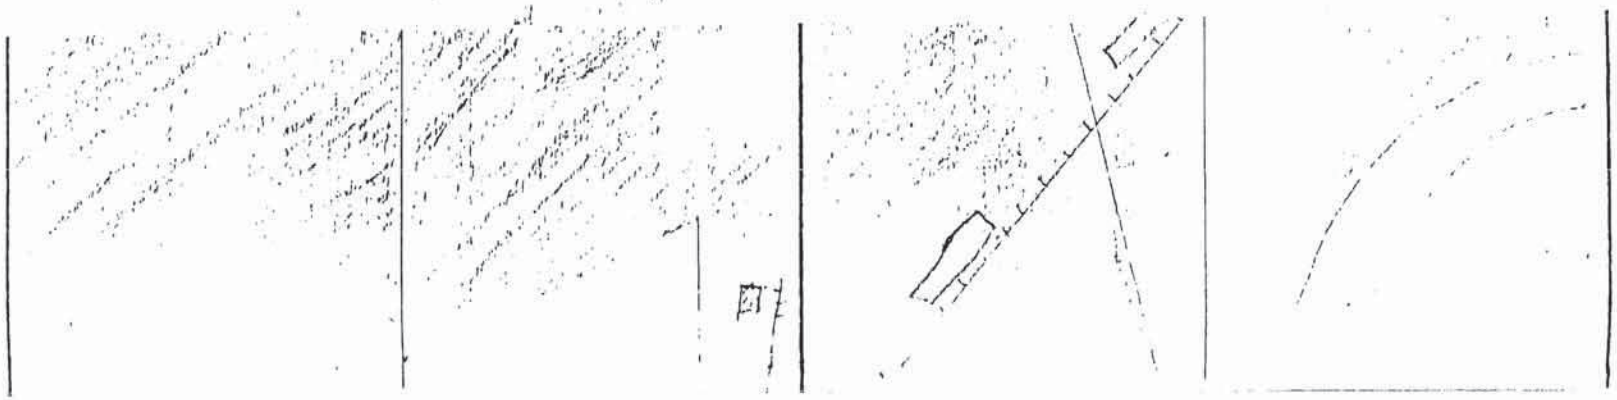
Operations are carried on in a 12 foot stratum of gypsum 80 feet below the surface. About 75% of the rock has been mined from about 1 acre of the ground. 2000 tons were mined last year and a like amount in 1909.

The mine was opened in 1896 and has been running about a quarter of the time since then.

The roof is not good, being full of faults or seams which makes the mine pretty wet. They are pumping about 150 gal. per minute.

Mr. Spooner states that the property is on too small a scale to be profitable and that he intends to shut it down during the coming year.

Powers Mine



From Grimsley, G. P., 1904, The Gypsum of Michigan and the Plaster Industry: Geological Survey of Michigan, Vol. IX, Pt. 2

The old work at the Godfrey mine was on the 11 foot ledge which has been removed over a large area extending from the wagon road at the east to the railroad switch to the mill at the west. The rock as far as we can judge from the fragments scattered around the quarry and from the account of the former foreman, Mr. A. J. Wright, was of the same general character as at the Alabastine mill.

A large portion of the old mill is still standing to the northwest of the quarry. It was a two and one-half story frame building equipped with a Godfrey double nipper and cracker for crushing the rock, and with two vertical disintegrators made by Butterworth and Lowe, for the fine

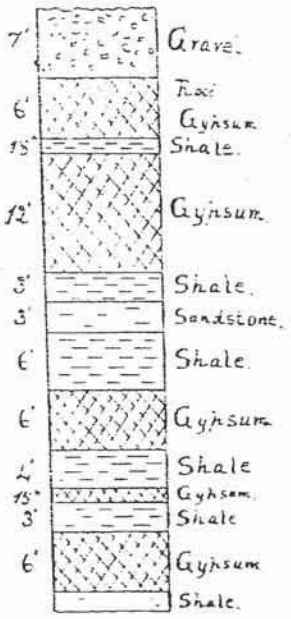


FIG. 14. Section at Powers' shaft.

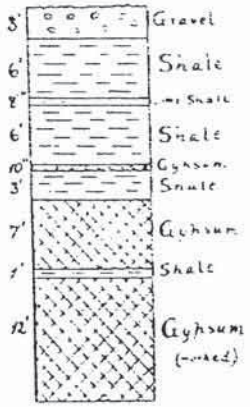

FIG. 15 Section Grand Rapids Plaster Co. mine.

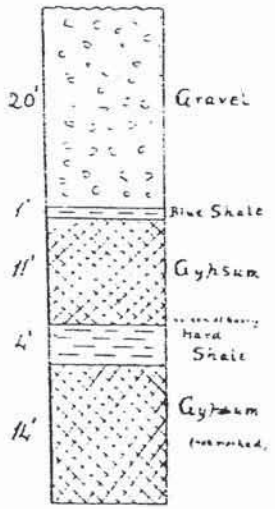

FIG. 16. Section Durr Mine

crushing and a single run of buhr stones. The mill was run by water power from Plaster creek. A separate building contained two ten foot kettles and the storage bins, but this was destroyed by fire a couple of years ago. A large roofed storage shed was built just south of the quarry and the rock was hauled in dump carts to the mill. The property is now idle and is owned by the Godfrey estate.

Powers Mine and Mill.

This property is located within the city on the west bank of the Grand river about midway between the Pearl and Fulton street bridges. Mr. Wm. T. Powers organized the company and sunk the shaft in 1896. The

mine goes 50 feet below the bed of the river and the framework of the shaft is built up 35 feet more to the floor of the mill. The record of the shaft has been lost and the section represented in Figure 14. is given from the memory of Mr. Powers of the boring made to the roof gypsum and 60 feet below it. The company owns 30 acres of this gypsum land. The upper ledge six to eight feet thick is left for a roof and the mine is worked on a room and pillar system with rooms about 50 feet square and the pillars 20 feet.

It is estimated that by this system about three-fourths of the gypsum can be removed.

The mill was built on the bank above in 1898, and was burned in the

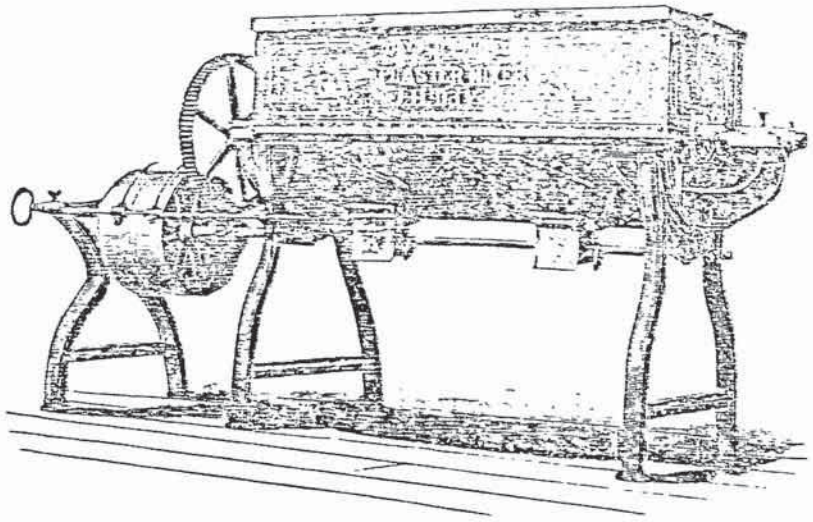

FIG. 17. Day's Lightning Plaster Mixer.

spring of 1903, and the company is known as the Gypsum Products Co. The frame mill was built in an L shape, 130 feet long east and west, and 25 to 50 feet wide with a storage shed built to the east 20 by 20 feet. The wareroom to the west was two stories high and the wider portion was three stories. On the second floor were placed the nipper and cracker and the buhrs below them in two sets, one of 36-inch for ordinary grinding, and a pair of 30-inch buhrs for regrinding. A part of the flour gypsum was carried by conveyors to the west part of the room and sacked for land plaster, and part was elevated to the third story over the kettle placed in the north part of the L extension. The gypsum then passed into the Powers patent kettle which was ten feet in diameter with a new design of flues described in the chapter on Technology, and it was heated by a wood fire. The finished plaster was dumped into fire brick bins and elevated to bins over the Broughton mixer where it was mixed with retarder to form wall plaster.

A special feature of the manufacture at this mill was the granite wall plaster, a sanded mixture ready to be mixed with water and applied to the wall. For this purpose there was on the basement floor a revolving cylinder sand dryer heated with wood fuel. The dried sand and retarder were mixed with the plaster of Paris in a Day's Lightning Plaster Mixer, as shown in Figure 17.

Grand Rapids Plaster Company Mines and Mills. (Plates X, XI, XV.)

On the north side of the river the gypsum is obtained from under the hill by an inclined hillside double entry tunnel. The Grand Rapids Plaster Co. have two double entry mines, one at each of their Eagle mills, known as mine No. 1 and mine No. 2. The main entry runs north and starts into the hill about the top of the 12 foot ledge. The section of the hill for 26 feet above the entry is given in Figure 15, a section which extends from the fence down, in Plate XV. About three feet of gravel are underlaid by 12 feet of shale separated at the center by eight inches of shaly limestone. Below the shale is a ten inch layer of gypsum seen in the photograph above the entry, and separated by three feet of shale from the six to seven foot upper ledge of gypsum. One foot of shale divides the upper from the 12 foot gypsum rock. The hill extends above to the wagon road 40 to 45 feet above the entry, and north of the road the hill rises 100 feet higher though not shown in the photograph.

The seven foot ledge is left for a roof and the 12 foot ledge is quarried for plaster rock. This is worked by a room and pillar system with rooms about 40 feet square and is mined by drilling holes in the upper half of the face of the rock and blasting down with dynamite. This leaves a bench or ledge six feet high which is then drilled vertically and blasted; all of the mining is carried on by this drift and bench system without any undercutting. Pillars of gypsum are left to support the roof, 15 to 20 feet in diameter and between the pillars intermediate timber posts are placed making the mines or caves as they are locally called, perfectly safe. No accidents from caving roof have ever occurred in mine No. 1. In No. 2 there has been no caving of the roof since 1881. At that time the roof covering about five acres fell in one night. The cause was in the placing the pillars too far apart, and the lack of sufficient intermediate posts. Since that time water has been somewhat troublesome in this mine, and about 150,000 gallons are pumped out in a week.

Mine No. 2 is similar to mine No. 1, and now the two are connected, and in all about 45 acres have been worked out. The character of the gypsum is about the same as in the quarries south of the river, showing a compact rock cut by numerous dark seams and with the red rock and the pencil rock at the bottom.

REPORT OF THE POWER'S MINE LOCATION
FOR THE
WEST RIVERBANK MIXED USE DEVELOPMENT
CITY OF GRAND RAPIDS

It has come to the attention of WBDC, while in the process of site analysis for the West Riverbank Mixed Use Development for the City of Grand Rapids, of the possible existance of an abandoned gypsum mine somewhere under the site. The following report may clarify some of the questions concerning location, size, and depth of the abandoned mine.

On Friday, September 28, 1894, the Evening Press ran an article on Page 3 about plans for a gypsum mine in the City of Grand Rapids. William T. Powers, a local industrial pioneer, stated that a vein of gypsum had been discovered on his property on the West Bank of the Grand River between Fulton and Pearl Streets. The article states that "the strata of rock is fourty feet thick and lies about eighty feet below the surface". It was Mr. Power's intention to sink a shaft, mine the gypsum and set up a gypsum products company on the riverbank. County records show that on June 2, 1896, Articles of Association were recorded and the Gypsum Products Manufacturing Company was formed. On record at the County Deeds Office is a deed selling property owned by William T. Powers and wife to Gypsum Products Mfg. Co. for the sum of $20,000.00. The following property description was given. "Commencing at a point on the south line of Pearl Street and fifty (50) feet east of the south east corner of Front and Pearl Streets thence south parallel with Front Street five hundred and sixteen (516) feet, thence west fifty feet (50) to the

east line of Front Street, thence south of the east line of Front Street one hundred and sixty six (166) feet, thence east one hundred (100) feet thence south parallel with Front Street one hundred and fifty (150) feet, thence south westerly about seventy five (75) feet to the north line of Lot Eight (8) Block Thirty (30) converse addition, before the same was vacated, thence southeasterly on the north line of Lot Eight (8) Block Thirty (30) to the center of Grand River, thence north on the center line of Grand River to the south line of Pearl Street bridge, thence west on the said south line of Pearl Street to the place of beginning." This description gives the boundaries of the Gypsum Products Mfg. Co.'s property and its mining limits.

According to the Geological Survey of Michigan, Vol. IX, Part II, The Gypsum of Michigan and the Plaster Industry by G.P. Grimsley dated 1901, William T. Powers began a 12' x 12' shaft in 1896. The shaft was located at the west end of the G.R. & I.R.R. bridge (presently the Penn Railroad Co. bridge) and mining was in a 12' layer of gypsum "about 60' below the riverbed". The article also made mention that the shaft was 85' in depth.

On July 23, 1901, a portion of the property described above was sold to the Grand Rapids Electric Light Company. Although the property was sold, the mining rights were retained. The Gypsum Products Mfg. Co. sold other land holdings around the mine, but always retained the mining rights to the limits that were previously described.

The most accurate information as to the exact location and size of the mine was recorded on July 9, 1907. Records at the Kent County Land Surveyor's Office show a survey of the mine for Valley City Milling Co. as follows:

FROM R & W 1-61
Survey of American Plaster Co. for Valley City Milling Co.
July 9, 1907

Measured E. along center of North
main track (G.R. & I.R.R.) from E. line of
Cold Storage Building
238' opposite center of shaft
52.3 N. from center of track to center of shaft

In mine ran from shaft N 82° 45' W

20'	52' RT.		55 LT.
40'	Pillar		Pillar
60'	55 RT. 40 LT.	73' RT. 42 LT. 15 RT.	59'
80'	Pillar		Pillar
100'	14' RT.		23'
115'	End of Working		

Ran from shaft S 44°E 79'

	S20° 45' W	93'	
86°RT.	N76° 30' W	72'	
76° 35' L	S27° 15' W	95'	11 RT. to edge of working

The survey not only pinpoints the exact location of the mine shaft, but also gives an indication of the size of the excavations. A map from a City atlas dated approximately 1910, shows the location of the Gypsum Products Mfg. Co. and surrounding buildings. Along with the preceding survey, the exact location in 1907 can be determined with fairly reliable accuracy (see attached Map #1).

The State Geological Survey has a short note on file concerning the Gypsum Products Mfg. Co.'s mine from a 1911 tax assessor's visit. Its contents are as follows:

Gypsum Products Manufacturing Company
J.W. Spooner General Manager, 44 Powers Theatre Building, Grand Rapids

This company owns about 8 acres on the west side of the River, mostly under the River, at the southeast corner of Front and Pearl Streets in the City of Grand Rapids. There is a small mill on the property. Operations are carried on in a 12 foot stratum of gypsum 80 feet below the surface. About 75% of the rock has been mined from about 1 acre of the ground. 2000 tons were mined last year and a like amount in 1909. The mine was opened in 1896 and has been running about a quarter of the time since then. The roof is not good, being full of faults or seams which makes the mine pretty wet. They are pumping about 150 gallons per minute. Mr. Spooner states that the property is on too small a scale to be profitable and that he intends to shut it down during the coming year.

County records indicate that the Gypsum Products Mfg. Co. was "dissolved by sale of property and franchises" in March of 1914, as recorded on January 25, 1915. A record of a deed also indicates on February 4, 1913, Gypsum Products Mfg. Co. sold its property and all its mining rights to the Michigan Railway Engineering Company. This transaction was recorded at the County Deeds Office on September 18, 1913.

There has been a great deal of speculation as to the true location of the Gypsum Products Mfg. Co.'s (or Power's) mine. After extensive research of City and County documents and records that resulted in the information given above, the following conclusions can be drawn with a reliable amount of accuracy.

Mr. William T. Powers began the mine in 1896. That same year, he formed the Gypsum Products Mfg. Co. and sold the land he owned along the Grand River where the mine was located to the Company for $20,000.00. Mr. Powers also acted as the head of the Company until his death in 1910.

At that time, he was succeeded by his son-in-law, J.W. Spooner. In the years following the founding of the Company, the balance of the land around the mine was sold to various interests. In each case, the Gypsum Products Mfg. Co. sold the land up to the river, and retained all the mining rights under the land being sold. It is interesting to note that the original land the Company owned went to the center of the Grand River, but when some of their holdings were sold, the property sold only went to the edge of the River. By 1910, the extent of the property that the Company owned was a small parcel on the bank of the River where the mine shaft and production buildings were located, and half of the River from just south of the railroad bridge to Pearl Street (see Map #2). The Company still had the mining rights to the entire original parcel. In 1907, we have a clear picture of the actual size of the mine from the Valley City Milling Co. survey (see Map #2). The mine was still in operation 5 years later and had grown to an area of about 1 acre in size at a depth of approximately 80'. The Gypsum Products Mfg. Co. was dissolved in 1914 and all property along with mining rights was sold the previous year to the railroad. There is no indication that the railroad continued the mining operation or sold the mine, and/or right to mine, to another holding. I could find no information that the mine has been filled following its close, as some have speculated. It is obvious that the shaft has been filled since an inspection of the site shows no indication of an open shaft. The condition of the mine at present time is pure speculation. The history of the mine shows a bad water problem and poor ceiling conditions, which would support the theory that in the past 70 years the mine cavity has been filled through natural actions.

Attention: Quinn Donnelly, P.E.

Reference: Summary of Grand River Sediment Sampling
Grand River Rapids Restoration
Grand Rapids, Michigan

Dear Mr. Donnelly:

We have completed sediment sampling at the twelve requested locations within the Grand River located downstream of the 6th Street Dam and upstream of the Fulton Street Bridge. The samples were collected using a petite Ponar Grab sampler on February 20, 2016. The Ponar sampler was lowered from a boat at the sampling locations to the river bottom, released to collect the sample and raised by hand after which the sample was retrieved by an MTC engineer. Retrieved samples were transported to our laboratory for gradation testing.

At each sampling location, approximately 12 to 15 attempts were made to collect a sample of the sediment at the river bottom using the Ponar sampler. Multiple attempts were necessary due to the presence of cobble and possible boulder which frequently resulted in little to no recover. At Sample Location 3, we were not able to collect a representative sample of the sediment.

Supplementary probing was performed along the sides of the boat in a repeatable pattern to subjectively evaluate the consistency of the river bottom based on (1) presence of cobble and boulder greater than or equal to 6-inches in size and (2) presence of sand, gravel and cobble smaller than 6-inches in size. A summary of sampling locations and the river bottom consistency based on probing efforts is provided in Table 1.

Table 1 – Sampling Location Summary

Sample Location	Location (MI State Plane South)		Water Depth (ft)	River Bottom Consistency Based on Probing (%)	
	Northing	Easting		< 6-inches	≥ 6-inches
1	536129	12773066	4.5	25	75
2	536295	12772921	4.0	10	90
3	536623	12772963	4.2	10	90
4	536936	12773212	2.5	15	85
5	537353	12773028	3.7	50	50
6	537428	12773240	3.0	60	40
7	537827	12773063	2.7	75	25
8	538296	12773381	3.9	40	60
9	538890	12773427	5.8	85	15
10	539147	12773180	3.5	50	50
11	539485	12773506	6.8	Suspected bedrock	
12	539801	12773238	3.7	15	85

Sieve analyses were performed on retrieved samples per ASTM D6913 with material larger than 2-inches measured individually using calipers. Photographs and sieve analysis results are attached.

We appreciate the opportunity to provide this service to you on this project. Should you have any questions or require further assistance, please contact our office.

Sincerely,

EXECUTIVE SUMMARY

Grand Rapids Whitewater has proposed improvements along an urban reach of the Grand River, in the City of Grand Rapids, Kent County, Michigan. Project Engineer, River Restoration, has retained Golder Associates, Inc. (Golder) to complete a wetland delineation report that would allow the State of Michigan Department of Environmental Quality (DEQ) to determine their regulatory authority over proposed activities within the investigation area pursuant to Section 404 of the Clean Water Act and Part 303 of the Natural Resources and Environmental Protection Act. DEQ has assigned the project file number 11-41-0105-P.

A preliminary review of available information pertaining to vegetation, soils, and hydrology in the project area was implemented prior to conducting a field investigation at the site. Sources of information included the United States Geological Survey (USGS), Natural Resource Conservation Service (NRCS), the National Wetland Inventory (NWI), Federal Emergency Management Agency (FEMA), and aerial photography (aerial imagery provided by the City of Grand Rapids GIS Department). Please see these resource figures included in Appendix A. These resources indicate the possible presence of wetlands and other waters under State and Federal jurisdiction at the project site.

Golder identified twelve (12) wetland areas totaling 3.09 acres and 6,428 linear-feet of a perennial stream (Grand River) within the 13.25-acre Grand River Whitewater Restoration Project site (Appendix A). These wetland areas continue off-site and outside of the investigation area and are associated with the Grand River. From aerial photographs, these wetlands appear to be contiguous with the littoral fringe of the Grand River; however, there are breaks in the physical indicators of an ordinary high water mark, which are devoid of vegetation or separated by sea walls and other man-made structures.

Golder conducted a wetland delineation of the subject project area in accordance with regulatory standards (Section 3). This report was prepared in accordance with regulatory guidance. If any impacts to potentially jurisdictional resources are proposed, Golder recommends submitting this report to the State of Michigan Department of Environmental Quality to request a wetland boundary confirmation and jurisdictional determination.[1]

[1] Wetlands are defined and regulated under the state's assumed §404 program and Natural Resources and Environmental Protection Act (MCL 324.30301 – 324.30323).

1.0 INTRODUCTION

Grand Rapids Whitewater is requesting confirmation of the wetland delineation conducted by Golder at the proposed project location for the Grand River Whitewater Restoration Project. The investigation areas were identified by the project engineer, RiverRestoration.Org, and include nine investigation areas encompassing 13.25 acres, located in the City of Grand Rapids, Kent County, Michigan, along the east and west banks of the Grand River (Appendix A). Collectively, the investigation areas are referred to as the "Investigation Area."

Federal wetlands and other Waters of the U.S. (WOUS) have legal protection in accordance with Section 404 of the Clean Water Act (CWA).[1] Since 1984, the State of Michigan has administered the CWA 404 permit program.[2] That is, the State of Michigan, through the Department of Environmental Quality (DEQ), has consistent but not identical authority and can provide federal authorization under the CWA. The Natural Resources and Environmental Protection Act (NREPA), Wetland Protection (Part 303) provides the regulatory authority over wetlands in Michigan.[3]

The DEQ generally requires the issuance of a permit, or coverage under an existing permit, for all actions that have the potential to degrade or modify protected resources. Per regulatory standard, the Investigation Area was surveyed for wetlands and other aquatic resources that may be regulated pursuant to DEQ authority.[4] Jurisdictional wetlands are distinguished from non-wetlands using specific criteria related to the hydrology, soil, and vegetative of an area.

For the purpose of this report, discussion of aquatic resources occurring within the project area is separated into uplands, wetlands and non-wetland waters, referred to herein as "water bodies." Water bodies refer to all waters that do not meet the wetland criteria (hydrophytic vegetation, hydric soils, and hydrology) as defined by the U.S. Army Corps of Engineers (USACE).[5] Specifically, unvegetated sections of the Grand River are categorized as water bodies. If these features (*i.e.*, wetlands or water bodies) are determined to be jurisdictional by DEQ, proposed activities within the features may be regulated.

Golder delineated twelve (12) wetland areas totaling 3.09 acres and 6,428 linear-feet of water bodies (*i.e.,* 0.64 acres of non-wetland waters) within the Investigation Area. Typically, DEQ asserts jurisdiction over contiguous wetlands, or those wetlands having a direct hydrological relationship with the water body.[6]

1 33 U.S.C. 1344.

2 40 CFR 233.1

3 Wetlands are defined and regulated under the state's assumed CWA 404 permitting program and Natural Resources and Environmental Protection Act (NREPA) Part 303 (MCL 324.30301 – 324.30323; MAC 281.921 – 281.925.).

4 33 CFR 328.3(a); NREPA 303 Section 324.30301.

5 USACE 1987.

6 Note that draft federal guidance published in April 2011 and a subsequent proposed rule change currently on public notice could supersede current regulatory guidance. Also, Michigan Legislature enacted Public Act 98, amending multiple parts of the Michigan environmental code regarding wetlands. The U.S. Environmental Protection Agency has said that changes to the administration of the CWA 404 program resulting from PA98 will not happen without federal approval.

Generally, wetlands with any permanent or intermittent surface water connection or within 500 feet of a stream are considered contiguous.[7] Activities in contiguous wetlands are regulated without regard to the size of the wetland. Therefore, it is assumed that each of the aquatic resources identified within the Investigation Area would be considered jurisdictional by DEQ.

This report represents the professional opinion of Golder regarding the presence or absence of wetlands and water bodies that may be jurisdictional and their boundaries within the Investigation Area. Resource maps depicting the Investigation Area are presented in Appendix B; photographs of the Investigation Area are included in Appendix C; and, data recorded during the investigation is included on wetland delineation forms in Appendix D.

[7] MCL 324.30301

2.0 PROJECT LOCATION AND DESCRIPTION

The Investigation Area totals 13.25 acres and is located along an urban stream corridor within the City of Grand Rapids, in Kent County, Michigan.[8] The Investigation Area is centered on the Grand River, approximately 25-miles east of Lake Michigan. The Grand River is the namesake for its parent watershed: the Lower Grand Watershed (HUC 04050006).

Ecological restoration and enhancement to the Grand River is being proposed as part of a multi-year public process involving amendments to the City of Grand Rapids' master plan. The Grand River Whitewater Project proposes to remove the Sixth Street Dam and install a new barrier, 5,500-feet upstream. A major focus of the proposal is to restore the City's namesake rapids, which were inundated and excavated more than 150-years ago. The proposal also includes plans to expand parks and tree canopy along the urban river.

Existing pedestrian trails provide access to the Investigation Area between Sixth Street and Fulton Street on both sides of the Grand River. Other access points provide access to the Investigation Area, including: from the parking lot at the northwest corner of the intersection of Monroe Avenue and Leonard Street, the parking lot of Charley's Crab Shack on Market Avenue, and from the grounds of the Gerald R. Ford Museum on Scribner Avenue.

8 Grand Rapids is the second-largest city in Michigan (after Detroit). U.S. Census Bureau. 2014. Available online at: http://www.census.gov/en.html#

3.0 METHODS

Prior to conducting field evaluations, Golder reviewed available in-office information including U.S. Geological Survey (USGS) mapping, soil survey data, aerial photography, wetland inventory mapping, and flood mapping (Appendix B).

- As depicted on the USGS Grand Rapids West Quadrangle, surface water drains toward the Grand River, which flows south through the Investigation Area. Aquatic resources within the Investigation Area are associated with the Grand River, which is identified as a Section 10 Navigable Water, downstream of the investigation area, from the Fulton Bridge to Lake Michigan.[9]
- NWI mapping depict aquatic features including:
  - A palustrine forested, broad-leaved deciduous freshwater wetlands that are temporarily flooded (PFO1A) that is contiguous with the Grand River, and
  - A riverine, lower perennial water having a substrate composed of unconsolidated materials that is permanently flooded (R2UBH).
- The Natural Resource Conservation Service's soil mapping depicts disturbed and altered soils (i.e., Urban land and Urban-Cohoctah complex). It appears that the soils have been leveled, dredged, and/or recently deposited. These soils vary greatly in important soil properties, including texture, permeability and drainage, but are primarily composed of sands and silts.
- The Federal Emergency Management Agency (FEMA) Floodplain map show that the Investigation Area is within the floodplain of the Grand Rapids River. The majority of the site is within the 100-year flood boundary; however, portions of the site exist within the 500-year floodplain.

Field investigations were conducted on June 11, 12, and 13 by Travis Morse of Golder, following and during substantial rain events. In consultation with DEQ, Golder performed a delineation of the Investigation Area in the field and using aerial photograph interpretation, due to complications with timing, access, size, and river stage.[10] Potential wetland areas were delineated and the individual acreages calculated.

Golder applied methodology specified by the 1987 *Corps of Engineers Wetlands Delineation Manual* (1987) and the 2012 *Regional Supplement to the Corps of Engineers Wetland Delineation Manual: Northcentral and Northeast Region* (Version 2.0) to perform a delineation of aquatic resources within the site.[11] Wetland determinations at sampling points were based on the (1) hydrophytic vegetation dominance, (2) presence of hydric soils, and (3) evidence or indications of wetland hydrology.

Positive indicators of wetland conditions for all three parameters are normally present in jurisdictional wetlands, as defined below.

9 List of Navigable Waters of the United States in Michigan. Available online at: https://www.michigan.gov/documents/deq/lwm-jpatm-appx-i_213469_7.pdf

10 DEQ meeting with project proponent and Golder, 6/12/14.

11 USACE 2012; USACE 1987.

1. Hydrophytic vegetation is defined as vegetation that is adapted to, and occurs in, areas where soils are frequently or permanently saturated of sufficient duration to exert a controlling influence on the plant species present. The hydrophytic vegetation parameter is met when one of the following is true: (a) the dominant vegetation (more than 50 percent of the dominant plant species) is typically adapted to areas having wetland hydrology and hydric soil conditions; (b) the prevalent vegetation is typically adapted to areas having wetland hydrology and hydric soil conditions (as determined by a formula); or (c) morphological adaptations are observed to confirm that plant species are growing in inundated or saturated conditions. Plants are assigned a Wetland Indicator Status based on their frequency of occurrence in wetland habitats.[12] Those ratings are as follows:

   A. UPL (Obligate Upland) = occur in wetlands in another region, but usually occur (estimated probability <99% in uplands in the region specified

   B. FAC (Facultative) = equally likely to occur in wetlands or non-wetlands (estimated probability 34 to 66%)

   C. FACW (Facultative Wetland) = usually occur in wetlands (estimated probability 67 to 99%), but occasionally found in non-wetlands

   D. FACU (Facultative Upland) = usually occur in non-wetlands (estimated probability 67to 99%), but occasionally found in wetlands (estimated probability 1 to 33%)

   E. OBL (Obligate Wetland) = occur usually (estimated probability >99%) in wetlands under natural conditions.

   Sampling locations are situated so that the data point best represents the vegetation present within the vegetative community at each plot. Plant species and their percent cover were recorded for each vegetative stratum generally using a 30-foot radius for trees, a 15-foot radius for shrubs, and a 5-foot radius for herbaceous plants and woody vines; however, some modification was necessary to limit sampling to the same community type.

2. Hydric soils, which are indicative of wetlands, are defined as soils that are sufficiently ponded, flooded, or saturated throughout the growing season to produce anaerobic conditions which favor the growth of hydrophytic vegetation. Hydric soils are identifiable based on observable properties that result from prolonged saturated-anaerobic conditions. Soil pits were dug at sample plot centers to 16 inches or refusal. Soil color and other characteristics were used to distinguish hydric versus non-hydric soils.[13] The Investigation Area contains fluvial deposits and sandy soils, which can be problematic hydric soils, and their proper identification requires additional information, such as landscape position, presence or absence of restrictive soil layers, and information about vegetation and hydrology.

3. Wetland hydrology refers to inundation and/or saturation of the soil by flooding or a shallow water table for a prolonged period during the growing season, such that the character of the soil and vegetation are substantially different from areas that do not experience inundation/saturation in this manner. The identification of wetland hydrology follows the USACE 1987 delineation manual. Geomorphic features associated with flooding (*e.g.*, channels, shorelines) and sediment deposits are example indicators of wetland hydrology. Wetland hydrology can be determined by documenting the presence of one primary indicator (such as watermarks on vegetation, drift deposits, sediment deposits, surface-scoured areas, algal mats, and oxidized root channels) or two secondary indicators (such as water-stained leaves, drainage patterns, geomorphic position, shallow aquitard, or a FAC-Neutral Test). The FAC-neutral test is performed by

12 Lichvar et al. 2014; USACE 2014.

13 Munsell 2009.

compiling a list of dominant plant species across all strata in the community, and dropping from the list any species with a Facultative indicator status (*i.e.*, FAC). The FAC-neutral test is met if more than 50 percent of the remaining dominant species are rated FACW and/or OBL.

Non-wetland waters were identified and delineated as water bodies based on the absence of one or more wetland criteria present below the ordinary high water mark.

4.0 RESULTS AND DISCUSSION

Based on the field investigation conducted by Golder during June of 2014, twelve (12) potentially jurisdictional wetlands were delineated within the Investigation Area (Table 1). Appendix A depicts the location of all aquatic resources noted during the survey. Photographs of the site and the vicinity of the site are included in Appendix C. Detailed notes on wetland sampling points can be found on wetland determination data forms which are included as Appendix D.

Table 1 Potentially Jurisdictional Aquatic Resources

Investigation Area	Acres	Aquatic Resource	Size (Acres)	Aquatic Resource	Length (linear-feet)
1	0.73	W12	0.12	Grand River	335.4
2	2.54	W11	0.11	Grand River	1237.29
		W10	0.02	Grand River

8	0.25	W2	0.12	Grand River	163.08
9	0.85	W1	0.08	Grand River	460.59
Totals	**13.25**		**3.09**		**6428.05**

Note:
1. Please note that where wetland polygons are open, these resources extend outside of the project area.

Data points are located in places that adequately represent the variation in vegetation, soils, and hydrologic regimes within the Investigation Area. The presence or absence of hydrophytic vegetation, hydric soil, and wetland hydrology indicators were documented for each sample plot to justify the delineated wetland boundaries.

The local USGS stream gauge on the Grand River (04119000) recorded flows during the survey between 3500 and 4200 cubic-feet-per-second (cfs). These flows are higher than average for June; however, these flows are still below the calculated ordinary high water mark. Additionally, a significant precipitation overlapped with the dates of the field survey and certain indicators of hydrology were considered unreliable (*e.g.*, soil saturation).

4.1.1 Uplands

The upland portions of the Investigation Area are the non-wetland areas above the ordinary high water mark. These areas contain naturally problematic fluvial deposits and sandy soils. The development of

hydric soil indicators in these soil types can be inhibited due to low iron or manganese content and/or low organic-matter content. The presence or absence of indicators of wetland vegetation and wetland hydrology were used to identify the hydric soil boundary.

Old fill material and construction debris are encountered in the soil profile and provide evidence of historic impacts. These materials may be classified as Udorthents; however, soil pits were limited to no deeper than 18 inches, so classification based on collected data is not possible.[14] In areas, primarily located at the north and south ends of the Investigation area, there are homeless camps, human latrines, and evidence of heavy foot-traffic. Historic soil disturbances can also compromise positive hydric soil determinations where fill activities include red materials (e.g., crushed bricks) that can appear to be redoximorphic features in the soil profile.

Four data points were recorded within two upland communities encountered during the field survey; (a) Successional Northern Hardwoods and (b) Managed Plant Community:

4.1.1.1 Successional Northern Hardwoods (Data Points 1, 5, and 8)

A successional northern hardwood community exists; however, the number of non-native species is explained by its metropolitan location. Trees are dominated largely by Boxelder (*Acer negundo*), Eastern Cottonwood (*Populus deltoides*), American Basswood (*Tilia americana*), Black Willow (*Salix nigra*), Austrian Pine (*Pinus nigra*), Russian-Olive (*Elaeagnus angustifolia*), American Elm (*Ulmus americana*), Siberian Elm (*U. pumila*), and White Mulberry (*Morus alba*) species.

The understory contains saplings and shrubs dominated by Boxelder (*A. negundo*), Staghorn Sumac (*Rhus typhina*), Black Locust (*Robinia pseudoacacia*), Green Ash (*Fraxinus pennsylvanica*), Northern Catalpa (*Catalpa speciosa*), Siberian Elm (*Ulmus pumila*), European Buckthorn (*Rhamnus cathartica*), Sandbar Willow (*Salix interior*), Fire Cherry (*Prunus pensylvanica*), Rambler Rose (*Rosa multiflora*), Red Osier (*Cornus alba*), and Twinsisters (*Lonicera tatarica*) species.

Herbaceous dicots are relatively diverse and contain several non-native and invasive species: Lesser Burdock (*Arctium minus*), American Yellow-Rocket (*Barbarea orthoceras*), Common Motherwort (*Leonurus cardiac*), Climbing Nightshade (*Solanum dulcamara*), Prickly Lettuce (*Lactuca serriola*), Poison Ivy (*Toxicodendron radicans*), Japanese Knotweed (*Polygonum cuspidum*), Common Milkweed (*Asclepias syriaca*), Oldfield Cinquefoil (*Potentilla simplex*), Red Clover (*Trifolium pretense*), Buck-Horn Plantain (*Plantago coronopus*), Yellow Sweet-Clover (*Melilotus officinalis*), Purple Loosestrife (*Lythrum salicaria*), and Blunt-Leaf Yellowcress (*Rorippa curvipes*). The herbaceous layer also contains seedlings of Sweet Sumac (*Rhus aromatic*) and White Mulberry (*Morus alba*).

[14] Udorthents contains durable refuse to at least 3 feet.

Upland graminoids existing in this community-type include Kentucky Blue Grass (*Poa pratensis*), Orchard Grass (*Dactylis glomerata*), Pennsylvania sedge (*Carex pensylvanica*), Clustered Fescue (*Festuca paradoxa*), Reed Canary Grass (*Phalaris arundinacea*), Slender Wild Rye (*Elymus trachycaulus*), Smooth Brome (*Bromus inermis*), and Cheat Grass (*B. tectorum*). River-Bank Grape (*Vitis riparia*) is a species of vine that is locally abundant.

Vegetation was evaluated for hydrophytic dominance or other affinity to wetland conditions by calculating the prevalence index. The prevalence index ranges from one to five. A prevalence index of 3.0 or less indicates that hydrophytic vegetation is present. Vegetation data was negative for hydrophytic vegetation and the prevalence index calculation for each of the upland areas is indicative of an upland plant community.

Surface soils within this community are typically a very dark grayish brown (10YR 3/2) loamy sand over dark brown (10YR 4/3) loamy sand. However, portions of the substrate have a shallow A Horizon that is a light olive brown (2.5Y 5/3) sandy loam over a very dark grayish brown (10YR 3/2) sandy loam layer containing gravel. Shovel refusal was experienced at approximately 1-foot below the surface on what appears to be old boulder-riprap in various locations.

4.1.1.2 Managed Plant Community (Data Point 4)

A portion of this community type, located in Ah-Nab-Awen Park, exhibited indicators of hydrology, including its geomorphic position, sparsely vegetated concave surfaces, and sediment and drift deposits (e.g., silt lines on tree bark and debris piled against upstream side of rocks and trees). However, the vegetative community is dominated by non-wetland species, including White Mulberry (*Morus alba*), Black Locust (*Robinia pseudoacacia*), Eastern Cottonwood (*Populus deltoides*), Amur Maple (*Acer ginnala*), Norway Maple (*A. platanoides*), American Elm (*Ulmus americana*), Red Oak (*Quercus rubra*), and Austrian Pine (*Pinus nigra*) trees. The sapling component is largely dominated by European Buckthorn (*Rhamnus cathartica*) along the successional northern hardwood interface. Pruned shrubs appear planted and consist of Burningbush (*Euonymus alatus*) and Twinsisters (*Lonicera tatarica*). The herbaceous community is manicured Kentucky Blue Grass (*Poa pratensis*), with several ruderal colonists of Yellow Sweet Clover (*Melilotus officinalis*), Prostrate Speedwell (*Veronica prostrate*), Common Dandelion (*Taraxacum officinale*), English Plantain (*Plantago lanceolata*). Unmanaged areas at the same landscape position are dominated by successional northern hardwoods and vegetative management does not appear to compromise the integrity of a non-hydrophytic determination. The invasive Reed Canary Grass (*Phalaris arundinacea*) was identified east of Data Point 4.

Soils here are a yellowish brown (10YR 5/4) color until about 10-inches below the surface, where they become very dark gray (10YR 3/1).

4.1.2 Aquatic Resources

Aquatic resources identified in the Investigation Area are wetlands and areas below the ordinary high water mark that are absent wetland soils, wetland hydrology or wetland vegetation. The ordinary high water line is based on the mean annual flood flow of 19,000 cfs and was calculated and identified by the project engineer, RiverRestoration. This was determined by obtaining the peak flow rates for each year from USGS for the downtown gauge over the period of recorded data, which dates back to 1901 and taking the average value. This flow rate was modeled one-dimensionally in HEC-RAS using a corrective model based on the FEMA flood model. The water surface elevation at each cross-section was assigned to a polyline in AutoCAD Civil 3d representing that location, a water surface was the generated using these as break lines. The intersection of this water surface with the existing surface was extracted as a polyline and is displayed as the ordinary high water line (Appendix A).

Seven data points were recorded within two wetland communities found at the Investigation Area: (a) Floodplain Forest and (b) Emergent Marsh:

4.1.2.1 *Floodplain Forest* (Data Points 2, 3, 6, 7, and 10)

Portions of the Investigation Area exist within the active floodplain of the Grand River. These areas have a flood disturbance cycle that results in the annual deposition of new soil material. Although certain indicators of wetland hydrology (*e.g.*, soil saturation, high water table,) are compromised by concurrent precipitation events, positive indicators include sediment deposits, inundation visible on aerial imagery, sparsely vegetated concave surfaces, geomorphic position, and microtopographic relief. Additionally, the vegetation of the community type satisfies the FAC-Neutral Test.

Sediment deposits (*i.e.*, thin layers or coatings of fine-grained mineral material) are evident on tree bark, leaves, and rocks that surface waters have recently covered the data point location. Sediment deposits indicate where water has stood for sufficient time to allow suspended sediment to settle. The upper edge of the sediment deposit reflects a water-surface elevation that was extrapolated across lower elevation areas to limit the extent of the sample. Additionally, leaf litter was evaluated for indicators of hydrology by the presence of water-stained leaves, which are grayish and blackish in color due to inundation for long periods; whereas, litter is dominated by faded yellow colors outside of the wetland.

Dominant tree species include Eastern Cottonwood (*Populus deltoides*), American Elm (*Ulmus americana*), American Sycamore (*Platanus occidentalis*), Black Willow (Salix nigra), Silver Maple (Acer saccharinum), Green Ash (*Fraxinus pennsylvanica*), and River Birch (*Betula nigra*).

The understory contains shrubs and sapling species, dominated by young Boxelder (*Acer negundo*), Silver Maple (*A. saccharinum*), Green Ash (*Fraxinus pennsylvanica*), Black Willow (*Salix nigra*), American Elm (*Ulmus americana*), and European Buckthorn (*Rhamnus cathartica*).

The herbaceous layer of the floodplain forest is sparsely vegetated, but contains Purple loosestrife (*Lythrum salicaria*), Flat-Top Goldernrod (*Euthamia graminifolia*), Parasol Whitetop (*Doellingeria umbellata*), Reed Canary Grass (*Phalaris arundinacea*), Common Ninebark (*Physiocarpus opulifolius*), Virginia Creeper (*Parthenocissus quinquefolia*), Wooly Sedge (*Carex pellita*), False-Spike Hedge Nettle (*Boehmeria cylindrical*), Common Red Raspberry (*Rubus idaeus*), River-Bank Grape (*Vitis riparia*), and seedling Silver Maple (*Acer saccharinum*) species.

Soils within the floodplain forest typically exhibit a shallow surface layer that is a grayish brown (2.5Y 5/2) sandy loam with few fine distinct black (5Y 2.5/1) mottles (*i.e.*, sandy redox). Redox concentrations can sometimes be found between soil stratifications in areas where organic matter is buried. However, in portions of this community has soils that exhibit a shallow, a grayish brown (2.5Y 5/2) sandy loam surface layer. At approximately 5-inches below the surface, the soil becomes a very dark grayish brown (2.5Y 3/2) and contains few ¾" gravel. Large rock exists at approximately 14-inches below the soil surface and prevents excavation with a hand-shovel to deeper depths. At approximately 6 inches, the soils are a dark brown (10YR 4/3) fine sandy loam containing ¾" gravel. At other locations, the top 12-inches of the substrate are composed of black (7.5YR 2.5/1) mucky sand, containing prominent strong brown (7.5YR 4/6) mottles over a dark gray (10YR 4/1) sandy silt loam containing faint reddish-brown (5YR 4/4) mottles.

Problematic soils occur within this community type, on vegetated bars within the active channel and above the bankfull level of the Grand River. Hydric soils are difficult to identify in sandy soils, especially along fluvial systems, because wetland indicators may be missing due to natural processes or recent disturbances. These soils are also problematic because of its proximity and relationship to the Grand River. Fluvial deposits within floodplains occur on vegetated bars within the active channel and above the bankfull level of the Grand River. In some cases, these soils may lack hydric soil indicators due to their sandy characteristics or due to recent deposition of soil material that has not had time sufficient to develop hydric soil indicators.

These soils are a very dark grayish brown (10YR 3/2) sandy loam, frequently over old boulder riprap, and lack hydric soil indicators. These soils likely lack hydric indicators due to seasonal or annual deposition of new soil material, low iron or manganese content, and/or low organic-matter content. Soils lacking hydric soil indicators are assumed hydric because hydrology and vegetation criteria are satisfied.

4.1.2.2 *Emergent Marsh* (Data Points 9 and 11)

The emergent marsh community was largely inundated during the field survey. Certain indicators of hydrology can provide false-positives relative to precipitation events or are inappropriate due to being contiguous with the fringe of the river. Reliable indicators of hydrology within this community include inundation, saturation, a high water table, water marks, sediment deposits, drift deposits, inundation visible on aerial imagery, and water-stained leaves.

Water marks provide evidence of inundation at the data point in the form of discolorations on the bark of woody vegetation and rocks. The water marks collectively form a level plane that can be viewed from one object to another. Sediment deposits are thin coatings of silt that remain on tree bark, plant stems and leaves, and large driftwood after surface waters recede. Drift deposits consist of rafted debris (i.e., waterborne branches, stems, leaves, and man-made litter that have been deposited on the ground surface and entangled in vegetation. Drift deposits are widely distributed across the dewatered area of the data points and are piled against the upstream sides of trees and rocks.

Additionally, the vegetation of this community type pass a FAC-Neutral Test. Characteristic riparian trees that are rooted within this community include Black Willow (*Salix nigra*), Silver Maple (*Acer saccharinum*), Green Ash (*Fraxinus pennsylvanica*), and American Elm (*Ulmus americana*), with a few young willow *S. nigra*) and maple (*A. saccharinum*) saplings over Red Osier (*Cornus sericea*) shrubs. However, woody vegetation represent less than significant total cover (*i.e.,* 8%). The herbaceous community contains Duck Potato (*Sagittaria peltatum*), Broad-Leaf Cat-Tail (*Typha latifolia*), Duck Potato (Sagittaria latifolia), Pale Yellow-Iris (*Iris pseudocarus*), Creeping-Jenny (*Lysimachia nummularia*), and Crested Sedge (*Carex cristatella*).

Soils are predominately black (10YR 2/1) to a very dark gray (10YR 3/1) sandy loam, over a dark gray (10YR 4/1) sandy loam. Soils were determined to be hydric at these locations due to the presence of a layer of sandy mucky material (Indicator S1) and/or having a dark surface (Indicator S7).

5.0 CONCLUSION

Within the 13.25-acre Investigation Area, Golder identified:

- 3.09 acres of wetland
- 6428 linear-feet of a perennial stream (Grand River)
- 0.64 acres of non-wetland waters

It is Golder's professional opinion that each of these aquatic resources identified within the Investigation Area would be considered jurisdictional by DEQ.

If plans require disturbing or filling of aquatic resources, coordination with DEQ will be required. The results of the delineation should be submitted to the DEQ for concurrence prior to the development of the proposed project.

*EXPLANATION OF ZONE DESIGNATIONS

ZONE	EXPLANATION
A	Areas of 100-year flood; base flood elevations and flood hazard factors not determined.
A0	Areas of 100-year shallow flooding where depths are between one (1) and three (3) feet; average depths of inundation are shown, but no flooc hazard factors are determined.
AH	Areas of 100-year shallow flooding where depths are between one (1) and three (3) feet; base flood elevations are shown, but no flood hazard factors are determined.
A1-A30	Areas of 100-year flood; base flood elevations and flood hazard factors determined.
A99	Areas of 100-year flood to be protected by flood protection system under construction; base flood elevations and flood hazard factors not determined.
B	Areas between limits of the 100-year flood and 500-year flood; or certain areas subject to 100-year flooding with average depths less than one (1) foot or where the contributing drainage area is less than one square mile; or areas protected by levees from the base flood. (Medium shading)
C	Areas of minimal flooding. (No shading)
D	Areas of undetermined, but possible, flood hazards.
V	Areas of 100-year coastal flood with velocity (wave action); base flood elevations and flood hazard factors not determined.
V1-V30	Areas of 100-year coastal flood with velocity (wave action); base flood elevations and flood hazard factors determined.

NOTES TO USER

Certain areas not in the special flood hazard areas (zones A and V) may be protected by flood control structures.

This map is for flood insurance purposes only; it does not necessarily show all areas subject to flooding in the community or all planimetric features outside special flood hazard areas.

For adjoining map panels, see separately printed Index To Map Panels.

APPENDIX D
WETLAND DETERMINATION DATA FORMS

WETLAND DETERMINATION DATA FORM – Northcentral and Northeast Region

Project/Site: Grand River Whitewater Restoration Project City/County: Kent Sampling Date: 6/11/14

Applicant/Owner: City of Grand Rapids State: MI Sampling Point: D1

Investigator(s): Travis Morse Section, Township, Range:

Landform (hillside, terrace, etc.): hillslope Local relief (concave, convex, none): convex Slope (%): 4

Subregion (LRR or MLRA): LRR L Lat: 42.960904853 Long: -85.67723631 Datum: NAD 83

Soil Map Unit Name: Urban Land NWI classification: N/A

Are climatic / hydrologic conditions on the site typical for this time of year? Yes x No ____ (If no, explain in Remarks.)

Are Vegetation ____, Soil ____, or Hydrology ____ significantly disturbed? Are "Normal Circumstances" present? Yes x No ____

Are Vegetation ____, Soil x, or Hydrology ____ naturally problematic? (If needed, explain any answers in Remarks.)

SUMMARY OF FINDINGS – Attach site map showing sampling point locations, transects, important features, etc.

Hydrophytic Vegetation Present?	Yes ____	No x	**Is the Sampled Area**		
Hydric Soil Present?	Yes ____	No x	**within a Wetland?**	**Yes** ____	**No** x
Wetland Hydrology Present?	Yes ____	No x	If yes, optional Wetland Site ID:		

Remarks: (Explain alternative procedures here or in a separate report.)
Naturally problematic fluvial deposits/sandy soils. Sample taken near crest of shoulder to Grand River at approximately 607 ft in elevation, near the fence behind the Public Works building.Outside of sample, C&D bricks serve as armor below OHWM.

HYDROLOGY

Wetland Hydrology Indicators:

Primary Indicators (minimum of one is required; check all that apply)

- ____ Surface Water (A1)
- ____ High Water Table (A2)
- ____ Saturation (A3)
- ____ Water Marks (B1)
- ____ Sediment Deposits (B2)
- ____ Drift Deposits (B3)
- ____ Algal Mat or Crust (B4)
- ____ Iron Deposits (B5)
- ____ Inundation Visible on Aerial Imagery (B7)
- ____ Sparsely Vegetated Concave Surface (B8)
- ____ Water-Stained Leaves (B9)
- ____ Aquatic Fauna (B13)
- ____ Marl Deposits (B15)
- ____ Hydrogen Sulfide Odor (C1)
- ____ Oxidized Rhizospheres on Living Roots (C3)
- ____ Presence of Reduced Iron (C4)
- ____ Recent Iron Reduction in Tilled Soils (C6)
- ____ Thin Muck Surface (C7)
- ____ Other (Explain in Remarks)

Secondary Indicators (minimum of two required)

- ____ Surface Soil Cracks (B6)
- ____ Drainage Patterns (B10)
- ____ Moss Trim Lines (B16)
- ____ Dry-Season Water Table (C2)
- ____ Crayfish Burrows (C8)
- ____ Saturation Visible on Aerial Imagery (C9)
- ____ Stunted or Stressed Plants (D1)
- ____ Geomorphic Position (D2)
- ____ Shallow Aquitard (D3)
- ____ Microtopographic Relief (D4)
- ____ FAC-Neutral Test (D5)

Field Observations:

Surface Water Present?	Yes ____	No x	Depth (inches): ____
Water Table Present?	Yes ____	No x	Depth (inches): ____
Saturation Present? (includes capillary fringe)	Yes ____	No x	Depth (inches): ____

Wetland Hydrology Present? **Yes** ____ **No** x

Describe Recorded Data (stream gauge, monitoring well, aerial photos, previous inspections), if available:

Remarks:
Rained intermittently all afternoon.

VEGETATION – Use scientific names of plants. Sampling Point: D1

Tree Stratum (Plot size: 30' r modified)	Absolute % Cover	Dominant Species?	Indicator Status
1. *Acer negundo*	85	Yes	FAC
2. *Morus alba*	20	No	FACU
3.			
4.			
5.			
6.			
7.			
	105	=Total Cover	
Sapling/Shrub Stratum (Plot size: 15' r modified)			
1. *Lonicera tatarica*	10	Yes	FACU
2. *Rhus typhina*	12	Yes	UPL
3. *Acer negundo*	15	Yes	FAC
4.			
5.			
6.			
7.			
	37	=Total Cover	
Herb Stratum (Plot size: 5' r)			
1. *Arctium minus*	30	Yes	FACU
2. *Solanum dulcamara*	5	No	FAC
3. *Leonurus cardiaca*	5	No	UPL
4. *Carex pensyvanica*	3	No	UPL
5. *Poa pratensis*	3	No	FACU
6.			
7.			
8.			
9.			
10.			
11.			
12.			
	46	=Total Cover	
Woody Vine Stratum (Plot size:)			
1. *Vitis riparia*	15	Yes	FAC
2.			
3.			
4.			
	15	=Total Cover	

Dominance Test worksheet:

Number of Dominant Species That Are OBL, FACW, or FAC: 3 (A)

Total Number of Dominant Species Across All Strata: 6 (B)

Percent of Dominant Species That Are OBL, FACW, or FAC: 50.0% (A/B)

Prevalence Index worksheet:

Total % Cover of:		Multiply by:	
OBL species	0	x 1 =	0
FACW species	0	x 2 =	0
FAC species	120	x 3 =	360
FACU species	63	x 4 =	252
UPL species	20	x 5 =	100
Column Totals:	203 (A)		712 (B)

Prevalence Index = B/A = 3.51

Hydrophytic Vegetation Indicators:

___ 1 - Rapid Test for Hydrophytic Vegetation

___ 2 - Dominance Test is >50%

___ 3 - Prevalence Index is ≤3.0[1]

___ 4 - Morphological Adaptations[1] (Provide supporting data in Remarks or on a separate sheet)

___ Problematic Hydrophytic Vegetation[1] (Explain)

[1]Indicators of hydric soil and wetland hydrology must be present, unless disturbed or problematic.

Definitions of Vegetation Strata:

Tree – Woody plants 3 in. (7.6 cm) or more in diameter at breast height (DBH), regardless of height.

Sapling/shrub – Woody plants less than 3 in. DBH and greater than or equal to 3.28 ft (1 m) tall.

Herb – All herbaceous (non-woody) plants, regardless of size, and woody plants less than 3.28 ft tall.

Woody vines – All woody vines greater than 3.28 ft in height.

Hydrophytic Vegetation Present? **Yes** ___ **No** x

Remarks: (Include photo numbers here or on a separate sheet.)

Modified width of sample plot to limited extent of same riparian community. Barbarea orthoceras outside of sample plot.

SOIL

Sampling Point: D1

Profile Description: (Describe to the depth needed to document the indicator or confirm the absence of indicators.)

Depth	Matrix		Redox Features					
(inches)	Color (moist)	%	Color (moist)	%	Type[1]	Loc[2]	Texture	Remarks
0-6	10YR 3/2	100					Sandy	loamy sand -old fill material
6-16	10YR 4/3	100					Sandy	loamy sand, some OM, sand grains visible

[1]Type: C=Concentration, D=Depletion, RM=Reduced Matrix, CS=Covered or Coated Sand Grains. [2]Location: PL=Pore Lining, M=Matrix.

Hydric Soil Indicators:

- ___ Histosol (A1)
- ___ Histic Epipedon (A2)
- ___ Black Histic (A3)
- ___ Hydrogen Sulfide (A4)
- ___ Stratified Layers (A5)
- ___ Depleted Below Dark Surface (A11)
- ___ Thick Dark Surface (A12)
- ___ Sandy Mucky Mineral (S1)
- ___ Sandy Gleyed Matrix (S4)
- ___ Sandy Redox (S5)
- ___ Stripped Matrix (S6)
- ___ Dark Surface (S7)
- ___ Polyvalue Below Surface (S8) (**LRR R, MLRA 149B**)
- ___ Thin Dark Surface (S9) (**LRR R, MLRA 149B**)
- ___ High Chroma Sands (S11) (**LRR K, L)**
- ___ Loamy Mucky Mineral (F1) (**LRR K, L**)
- ___ Loamy Gleyed Matrix (F2)
- ___ Depleted Matrix (F3)
- ___ Redox Dark Surface (F6)
- ___ Depleted Dark Surface (F7)
- ___ Redox Depressions (F8)
- ___ Marl (F10) (**LRR K, L**)

Indicators for Problematic Hydric Soils[3]:

- ___ 2 cm Muck (A10) (**LRR K, L, MLRA 149B**)
- ___ Coast Prairie Redox (A16) (**LRR K, L, R**)
- ___ 5 cm Mucky Peat or Peat (S3) (**LRR K, L, R**)
- ___ Polyvalue Below Surface (S8) (**LRR K, L**)
- ___ Thin Dark Surface (S9) (**LRR K, L**)
- ___ Iron-Manganese Masses (F12) (**LRR K, L, R**)
- ___ Piedmont Floodplain Soils (F19) (**MLRA 149B**)
- ___ Mesic Spodic (TA6) (**MLRA 144A, 145, 149B**)
- ___ Red Parent Material (F21)
- ___ Very Shallow Dark Surface (TF12)
- ___ Other (Explain in Remarks)

[3]Indicators of hydrophytic vegetation and wetland hydrology must be present, unless disturbed or problematic.

Restrictive Layer (if observed):

Type: _____

Depth (inches): _____

Hydric Soil Present? **Yes** ___ **No** x

Remarks:

Data form is revised from Northcentral and Northeast Regional Supplement Version 2.0 to reflect the NRCS Field Indicators of Hydric Soils version 7.0 March 2013 Errata. (http://soils.usda.gov/use/hydric)

WETLAND DETERMINATION DATA FORM – Northcentral and Northeast Region

Project/Site: Grand River Whitewater Restoration Project City/County: Kent Sampling Date: 6/11/14

Applicant/Owner: City of Grand Rapids State: MI Sampling Point: D2

Investigator(s): Travis Morse Section, Township, Range:

Landform (hillside, terrace, etc.): river bank Local relief (concave, convex, none): convex Slope (%): 0-2

Subregion (LRR or MLRA): LRR L Lat: 42.965104436 Long: -85.674604631 Datum:

Soil Map Unit Name: Urban Land NWI classification: R2UBH

Are climatic / hydrologic conditions on the site typical for this time of year? Yes x No (If no, explain in Remarks.)

Are Vegetation , Soil , or Hydrology significantly disturbed? Are "Normal Circumstances" present? Yes x No

Are Vegetation , Soil x , or Hydrology naturally problematic? (If needed, explain any answers in Remarks.)

SUMMARY OF FINDINGS – Attach site map showing sampling point locations, transects, important features, etc.

Hydrophytic Vegetation Present?	Yes X	No	**Is the Sampled Area**	
Hydric Soil Present?	Yes X	No	**within a Wetland?**	**Yes** X **No**
Wetland Hydrology Present?	Yes X	No	If yes, optional Wetland Site ID:	

Remarks: (Explain alternative procedures here or in a separate report.)
Fluvial deposits within floodplain; soil disturbance cycle/annual deposition of new soil material limits horizon development. Area satisfies wetland criteria; sample taken below OHWM.

HYDROLOGY

Wetland Hydrology Indicators:

Primary Indicators (minimum of one is required; check all that apply)

- Surface Water (A1)
- X High Water Table (A2)
- x Saturation (A3)
- Water Marks (B1)
- x Sediment Deposits (B2)
- Drift Deposits (B3)
- Algal Mat or Crust (B4)
- Iron Deposits (B5)
- x Inundation Visible on Aerial Imagery (B7)
- Sparsely Vegetated Concave Surface (B8)
- Water-Stained Leaves (B9)
- Aquatic Fauna (B13)
- Marl Deposits (B15)
- Hydrogen Sulfide Odor (C1)
- Oxidized Rhizospheres on Living Roots (C3)
- Presence of Reduced Iron (C4)
- Recent Iron Reduction in Tilled Soils (C6)
- Thin Muck Surface (C7)
- Other (Explain in Remarks)

Secondary Indicators (minimum of two required)

- Surface Soil Cracks (B6)
- Drainage Patterns (B10)
- Moss Trim Lines (B16)
- Dry-Season Water Table (C2)
- Crayfish Burrows (C8)
- Saturation Visible on Aerial Imagery (C9)
- Stunted or Stressed Plants (D1)
- Geomorphic Position (D2)
- Shallow Aquitard (D3)
- Microtopographic Relief (D4)
- X FAC-Neutral Test (D5)

Field Observations:

Surface Water Present?	Yes	No x	Depth (inches):	
Water Table Present?	Yes x	No	Depth (inches):	-6
Saturation Present? (includes capillary fringe)	Yes x	No	Depth (inches):	-6

Wetland Hydrology Present? **Yes** X **No**

Describe Recorded Data (stream gauge, monitoring well, aerial photos, previous inspections), if available:
Canopy cover on aerials. Anecdotal evidence: Client says area is frequently under water.

Remarks:
Rained intermittently all afternoon. Geomorphic Position (D2) is not applicable to the location along river and over sand and gravel substrate.

VEGETATION – Use scientific names of plants. Sampling Point: D2

Tree Stratum (Plot size: 30' r modified)	Absolute % Cover	Dominant Species?	Indicator Status
1. *Betula nigra*	5	Yes	FACW
2.			
3.			
4.			
5.

- ___ Iron-Manganese Masses (F12) (**LRR K, L, R**)
- ___ Piedmont Floodplain Soils (F19) (**MLRA 149B**)
- ___ Mesic Spodic (TA6) (**MLRA 144A, 145, 149B**)
- ___ Red Parent Material (F21)
- ___ Very Shallow Dark Surface (TF12)
- x Other (Explain in Remarks)

[3]Indicators of hydrophytic vegetation and wetland hydrology must be present, unless disturbed or problematic.

Restrictive Layer (if observed):

Type: _____

Depth (inches): _____

Hydric Soil Present? **Yes** X **No** ___

Remarks:

Saturated soils examined for redox features after drying to a moist condition. Buried organics are evidence of active floodplain. Data form is revised from Northcentral and Northeast Regional Supplement Version 2.0 to reflect the NRCS Field Indicators of Hydric Soils version 7.0 March 2013 Errata. (http://soils.usda.gov/use/hydric)

WETLAND DETERMINATION DATA FORM – Northcentral and Northeast Region

Project/Site: Grand River Whitewater Restoration Project City/County: Kent Sampling Date: 6/12/14

Applicant/Owner: City of Grand Rapids State: MI Sampling Point: D3

Investigator(s): Travis Morse Section, Township, Range:

Landform (hillside, terrace, etc.): river bank Local relief (concave, convex, none): convex Slope (%): 2-4

Subregion (LRR or MLRA): LRR L Lat: 42.96711621 Long: -85.67613005 Datum: NAD 83

Soil Map Unit Name: Urban Land NWI classification: R2UBH

Are climatic / hydrologic conditions on the site typical for this time of year? Yes x No ____ (If no, explain in Remarks.)

Are Vegetation ____, Soil ____, or Hydrology ____ significantly disturbed? Are "Normal Circumstances" present? Yes x No ____

Are Vegetation ____, Soil x, or Hydrology ____ naturally problematic? (If needed, explain any answers in Remarks.)

SUMMARY OF FINDINGS – Attach site map showing sampling point locations, transects, important features, etc.

Hydrophytic Vegetation Present?	Yes X	No ____	**Is the Sampled Area**		
Hydric Soil Present?	Yes x	No ____	**within a Wetland?**	**Yes** X	**No** ____
Wetland Hydrology Present?	Yes X	No ____	If yes, optional Wetland Site ID:		

Remarks: (Explain alternative procedures here or in a separate report.)
Fluvial deposits within floodplain; soil disturbance cycle/annual deposition of new soil material limits horizon development. Accessed from along foot path, approximately 100-feet south of the Interurban/Richard Gillette Bridge. Compared to similar conditions at DP2 below OHWM and on opposite bank, outside of IA.

HYDROLOGY

Wetland Hydrology Indicators:

Primary Indicators (minimum of one is required; check all that apply)

- ____ Surface Water (A1)
- ____ High Water Table (A2)
- ____ Saturation (A3)
- ____ Water Marks (B1)
- x Sediment Deposits (B2)
- ____ Drift Deposits (B3)
- ____ Algal Mat or Crust (B4)
- ____ Iron Deposits (B5)
- ____ Inundation Visible on Aerial Imagery (B7)
- ____ Sparsely Vegetated Concave Surface (B8)
- ____ Water-Stained Leaves (B9)
- ____ Aquatic Fauna (B13)
- ____ Marl Deposits (B15)
- ____ Hydrogen Sulfide Odor (C1)
- ____ Oxidized Rhizospheres on Living Roots (C3)
- ____ Presence of Reduced Iron (C4)
- ____ Recent Iron Reduction in Tilled Soils (C6)
- ____ Thin Muck Surface (C7)
- ____ Other (Explain in Remarks)

Secondary Indicators (minimum of two required)

- ____ Surface Soil Cracks (B6)
- ____ Drainage Patterns (B10)
- ____ Moss Trim Lines (B16)
- ____ Dry-Season Water Table (C2)
- ____ Crayfish Burrows (C8)
- ____ Saturation Visible on Aerial Imagery (C9)
- ____ Stunted or Stressed Plants (D1)
- ____ Geomorphic Position (D2)
- ____ Shallow Aquitard (D3)
- ____ Microtopographic Relief (D4)
- X FAC-Neutral Test (D5)

Field Observations:

Surface Water Present?	Yes ____	No x	Depth (inches): ____	
Water Table Present?	Yes ____	No x	Depth (inches): ____	
Saturation Present? (includes capillary fringe)	Yes ____	No x	Depth (inches): ____	**Wetland Hydrology Present?** **Yes** X **No** ____

Describe Recorded Data (stream gauge, monitoring well, aerial photos, previous inspections), if available:

Remarks:
Rain within past 24 hours. Along low-elevation fringe of river.

VEGETATION – Use scientific names of plants. Sampling Point: D3

Tree Stratum (Plot size: 30' r modified)	Absolute % Cover	Dominant Species?	Indicator Status
1. *Populus deltoides*	30	Yes	FAC

		=Total Cover	

Dominance Test worksheet:

Number of Dominant Species That Are OBL, FACW, or FAC: 5 (A)

Total Number of Dominant Species Across All Strata: 5 (B)

Percent of Dominant Species That Are OBL, FACW, or FAC: 100.0% (A/B)

Prevalence Index worksheet:

Total % Cover of:		Multiply by:	
OBL species	0	x 1 =	0
FACW species	108	x 2 =	216
FAC species	80	x 3 =	240
FACU species	0	x 4 =	0
UPL species	0	x 5 =	0
Column Totals:	188 (A)		456 (B)

Prevalence Index = B/A = 2.43

Hydrophytic Vegetation Indicators:

__ 1 - Rapid Test for Hydrophytic Vegetation

X 2 - Dominance Test is >50%

X 3 - Prevalence Index is ≤3.0[1]

__ 4 - Morphological Adaptations[1] (Provide supporting data in Remarks or on a separate sheet)

__ Problematic Hydrophytic Vegetation[1] (Explain)

[1]Indicators of hydric soil and wetland hydrology must be present, unless disturbed or problematic.

Definitions of Vegetation Strata:

Tree – Woody plants 3 in. (7.6 cm) or more in diameter at breast height (DBH), regardless of height.

Sapling/shrub – Woody plants less than 3 in. DBH and greater than or equal to 3.28 ft (1 m) tall.

Herb – All herbaceous (non-woody) plants, regardless of size, and woody plants less than 3.28 ft tall.

Woody vines – All woody vines greater than 3.28 ft in height.

Hydrophytic Vegetation Present? **Yes** X **No** __

Remarks: (Include photo numbers here or on a separate sheet.)

Modified width of sample plot to limited extent of same community. Doellingeria umbellata and Physiocarpus opulifolius outside sample.

SOIL

Sampling Point: D3

Profile Description: (Describe to the depth needed to document the indicator or confirm the absence of indicators.)

Depth	Matrix		Redox Features					
(inches)	Color (moist)	%	Color (moist)	%	Type[1]	Loc[2]	Texture	Remarks
0-5	2.5Y 5/2	100					Sandy	sandy loam - buried organics (twigs, bark)
5-14	2.5Y 3/2	100					Sandy	sandy loam, 3/4" gravel

[1]Type: C=Concentration, D=Depletion, RM=Reduced Matrix, CS=Covered or Coated Sand Grains. [2]Location: PL=Pore Lining, M=Matrix.

Hydric Soil Indicators:

- ___ Histosol (A1)
- ___ Histic Epipedon (A2)
- ___ Black Histic (A3)
- ___ Hydrogen Sulfide (A4)
- ___ Stratified Layers (A5)
- ___ Depleted Below Dark Surface (A11)
- ___ Thick Dark Surface (A12)
- ___ Sandy Mucky Mineral (S1)
- ___ Sandy Gleyed Matrix (S4)
- ___ Sandy Redox (S5)
- ___ Stripped Matrix (S6)
- ___ Dark Surface (S7)
- ___ Polyvalue Below Surface (S8) (**LRR R, MLRA 149B**)
- ___ Thin Dark Surface (S9) (**LRR R, MLRA 149B**)
- ___ High Chroma Sands (S11) (**LRR K, L)**
- ___ Loamy Mucky Mineral (F1) (**LRR K, L**)
- ___ Loamy Gleyed Matrix (F2)
- ___ Depleted Matrix (F3)
- ___ Redox Dark Surface (F6)
- ___ Depleted Dark Surface (F7)
- ___ Redox Depressions (F8)
- ___ Marl (F10) (**LRR K, L**)

Indicators for Problematic Hydric Soils[3]:

- ___ 2 cm Muck (A10) (**LRR K, L, MLRA 149B**)
- ___ Coast Prairie Redox (A16) (**LRR K, L, R**)
- ___ 5 cm Mucky Peat or Peat (S3) (**LRR K, L, R**)
- ___ Polyvalue Below Surface (S8) (**LRR K, L**)
- ___ Thin Dark Surface (S9) (**LRR K, L**)
- ___ Iron-Manganese Masses (F12) (**LRR K, L, R**)
- ___ Piedmont Floodplain Soils (F19) (**MLRA 149B**)
- ___ Mesic Spodic (TA6) (**MLRA 144A, 145, 149B**)
- ___ Red Parent Material (F21)
- ___ Very Shallow Dark Surface (TF12)
- x Other (Explain in Remarks)

[3]Indicators of hydrophytic vegetation and wetland hydrology must be present, unless disturbed or problematic.

Restrictive Layer (if observed):

Type: Riprap boulders

Depth (inches): 14+

Hydric Soil Present? **Yes** x **No** ___

Remarks:

Sandy fluvial deposits are naturally problematic. Buried organics are evidence of active floodplain. Data form is revised from Northcentral and Northeast Regional Supplement Version 2.0 to reflect the NRCS Field Indicators of Hydric Soils version 7.0 March 2013 Errata. (http://soils.usda.gov/use/hydric)

Hydrophytic Vegetation Indicators:

___ 1 - Rapid Test for Hydrophytic Vegetation

___ 2 - Dominance Test is >50%

___ 3 - Prevalence Index is ≤3.0[1]

___ 4 - Morphological Adaptations[1] (Provide supporting data in Remarks or on a separate sheet)

___ Problematic Hydrophytic Vegetation[1] (Explain)

[1]Indicators of hydric soil and wetland hydrology must be present, unless disturbed or problematic.

Definitions of Vegetation Strata:

Tree – Woody plants 3 in. (7.6 cm) or more in diameter at breast height (DBH), regardless of height.

Sapling/shrub – Woody plants less than 3 in. DBH and greater than or equal to 3.28 ft (1 m) tall.

Herb – All herbaceous (non-woody) plants, regardless of size, and woody plants less than 3.28 ft tall.

Woody vines – All woody vines greater than 3.28 ft in height.

Hydrophytic Vegetation Present? **Yes** ___ **No** x

Remarks: (Include photo numbers here or on a separate sheet.)

Modified width of sample plot to limited extent of same community. Just outside of sample there are mature Rhamnus cathartica, Acer platanoides, Quercus rubra, and Pinus nigra. Mowing, seeding, and planting of community does not make the hydrophytic vegetation determination unreliable. Unmanaged reference site (within treeline ~25 north, similar soils and hydrologic conditions) contains upland vegetation.

- ___ Loamy Mucky Mineral (F1) (**LRR K, L**)
- ___ Loamy Gleyed Matrix (F2)
- ___ Depleted Matrix (F3)
- ___ Redox Dark Surface (F6)
- ___ Depleted Dark Surface (F7)
- ___ Redox Depressions (F8)
- ___ Marl (F10) (**LRR K, L**)

Indicators for Problematic Hydric Soils[3]:

- ___ 2 cm Muck (A10) (**LRR K, L, MLRA 149B**)
- ___ Coast Prairie Redox (A16) (**LRR K, L, R**)
- ___ 5 cm Mucky Peat or Peat (S3) (**LRR K, L, R**)
- ___ Polyvalue Below Surface (S8) (**LRR K, L**)
- ___ Thin Dark Surface (S9) (**LRR K, L**)
- ___ Iron-Manganese Masses (F12) (**LRR K, L, R**)
- ___ Piedmont Floodplain Soils (F19) (**MLRA 149B**)
- ___ Mesic Spodic (TA6) (**MLRA 144A, 145, 149B**)
- ___ Red Parent Material (F21)
- ___ Very Shallow Dark Surface (TF12)
- ___ Other (Explain in Remarks)

[3]Indicators of hydrophytic vegetation and wetland hydrology must be present, unless disturbed or problematic.

Restrictive Layer (if observed):

Type: cobbles. Boulders

Depth (inches): 12+

Hydric Soil Present? **Yes** ___ **No** x

Remarks:

Old riprap prevents deep sampling. Data form is revised from Northcentral and Northeast Regional Supplement Version 2.0 to reflect the NRCS Field Indicators of Hydric Soils version 7.0 March 2013 Errata. (http://soils.usda.gov/use/hydric)

WETLAND DETERMINATION DATA FORM – Northcentral and Northeast Region

Project/Site: Grand River Whitewater Restoration Project City/County: Kent Sampling Date: 6/12/14

Applicant/Owner: City of Grand Rapids State: MI Sampling Point: D6

Investigator(s): Travis Morse Section, Township, Range:

Landform (hillside, terrace, etc.): terrace Local relief (concave, convex, none): concave Slope (%): 0-2

Subregion (LRR or MLRA): LRR L Lat: 42.97372178 Long: -85.67555809 Datum: NAD 83

Soil Map Unit Name: Urban Land NWI classification: R2UBH

Are climatic / hydrologic conditions on the site typical for this time of year? Yes x No ____ (If no, explain in Remarks.)

Are Vegetation ____, Soil ____, or Hydrology ____ significantly disturbed? Are "Normal Circumstances" present? Yes x No ____

Are Vegetation ____, Soil X, or Hydrology ____ naturally problematic? (If needed, explain any answers in Remarks.)

SUMMARY OF FINDINGS – Attach site map showing sampling point locations, transects, important features, etc.

Hydrophytic Vegetation Present?	Yes X	No ____	**Is the Sampled Area**
Hydric Soil Present?	Yes x	No ____	**within a Wetland?** **Yes** x **No** ____
Wetland Hydrology Present?	Yes X	No ____	If yes, optional Wetland Site ID:

Remarks: (Explain alternative procedures here or in a separate report.)
Sandy fluvial deposits are naturally problematic.

HYDROLOGY

Wetland Hydrology Indicators:

Primary Indicators (minimum of one is required; check all that apply)

____ Surface Water (A1)	____ Water-Stained Leaves (B9)	____ Surface Soil Cracks (B6)
X High Water Table (A2)	____ Aquatic Fauna (B13)	____ Drainage Patterns (B10)
x Saturation (A3)	____ Marl Deposits (B15)	____ Moss Trim Lines (B16)
____ Water Marks (B1)	____ Hydrogen Sulfide Odor (C1)	____ Dry-Season Water Table (C2)
x Sediment Deposits (B2)	____ Oxidized Rhizospheres on Living Roots (C3)	____ Crayfish Burrows (C8)
x Drift Deposits (B3)	____ Presence of Reduced Iron (C4)	____ Saturation Visible on Aerial Imagery (C9)
____ Algal Mat or Crust (B4)	____ Recent Iron Reduction in Tilled Soils (C6)	____ Stunted or Stressed Plants (D1)

Dominance Test worksheet:

Number of Dominant Species That Are OBL, FACW, or FAC: 3 (A)

Total Number of Dominant Species Across All Strata: 4 (B)

Percent of Dominant Species That Are OBL, FACW, or FAC: 75.0% (A/B)

Prevalence Index worksheet:

Total % Cover of:		Multiply by:	
OBL species	28	x 1 =	28
FACW species	88	x 2 =	176
FAC species	7	x 3 =	21
FACU species	15	x 4 =	60
UPL species	0	x 5 =	0
Column Totals:	138	(A)	285 (B)

Prevalence Index = B/A = 2.07

Hydrophytic Vegetation Indicators:

- ___ 1 - Rapid Test for Hydrophytic Vegetation
- X 2 - Dominance Test is >50%
- X 3 - Prevalence Index is ≤3.0[1]
- ___ 4 - Morphological Adaptations[1] (Provide supporting data in Remarks or on a separate sheet)
- ___ Problematic Hydrophytic Vegetation[1] (Explain)

[1]Indicators of hydric soil and wetland hydrology must be present, unless disturbed or problematic.

Definitions of Vegetation Strata:

Tree – Woody plants 3 in. (7.6 cm) or more in diameter at breast height (DBH), regardless of height.

Sapling/shrub – Woody plants less than 3 in. DBH and greater than or equal to 3.28 ft (1 m) tall.

Herb – All herbaceous (non-woody) plants, regardless of size, and woody plants less than 3.28 ft tall.

Woody vines – All woody vines greater than 3.28 ft in height.

Hydrophytic Vegetation Present? **Yes** X **No** ___

Remarks: (Include photo numbers here or on a separate sheet.)

Modified width of sample plot to limited extent of same community. Lythrum salicoria defoliated (Galerucella beetles?). Chrysemys picta basking outside sample in river.

SOIL

Sampling Point: D6

Profile Description: (Describe to the depth needed to document the indicator or confirm the absence of indicators.)

Depth (inches)	Matrix Color (moist)	Matrix %	Redox Features Color (moist)	Redox Features %	Type[1]	Loc[2]	Texture	Remarks
0-8	10YR 3/2	100					Sandy	sandy loam; refusal - old boulder riprap

[1]Type: C=Concentration, D=Depletion, RM=Reduced Matrix, CS=Covered or Coated Sand Grains. [2]Location: PL=Pore Lining, M=Matrix.

Hydric Soil Indicators:

- ___ Histosol (A1)
- ___ Histic Epipedon (A2)
- ___ Black Histic (A3)
- ___ Hydrogen Sulfide (A4)
- ___ Stratified Layers (A5)
- ___ Depleted Below Dark Surface (A11)
- ___ Thick Dark Surface (A12)
- ___ Sandy Mucky Mineral (S1)
- ___ Sandy Gleyed Matrix (S4)
- ___ Sandy Redox (S5)
- ___ Stripped Matrix (S6)
- ___ Dark Surface (S7)
- ___ Polyvalue Below Surface (S8) (**LRR R, MLRA 149B**)
- ___ Thin Dark Surface (S9) (**LRR R, MLRA 149B**)
- ___ High Chroma Sands (S11) (**LRR K, L)**
- ___ Loamy Mucky Mineral (F1) (**LRR K, L**)
- ___ Loamy Gleyed Matrix (F2)
- ___ Depleted Matrix (F3)
- ___ Redox Dark Surface (F6)
- ___ Depleted Dark Surface (F7)
- ___ Redox Depressions (F8)
- ___ Marl (F10) (**LRR K, L**)

Indicators for Problematic Hydric Soils[3]:

- ___ 2 cm Muck (A10) (**LRR K, L, MLRA 149B**)
- ___ Coast Prairie Redox (A16) (**LRR K, L, R**)
- ___ 5 cm Mucky Peat or Peat (S3) (**LRR K, L, R**)
- ___ Polyvalue Below Surface (S8) (**LRR K, L**)
- ___ Thin Dark Surface (S9) (**LRR K, L**)
- ___ Iron-Manganese Masses (F12) (**LRR K, L, R**)
- ___ Piedmont Floodplain Soils (F19) (**MLRA 149B**)
- ___ Mesic Spodic (TA6) (**MLRA 144A, 145, 149B**)
- ___ Red Parent Material (F21)
- ___ Very Shallow Dark Surface (TF12)
- X Other (Explain in Remarks)

[3]Indicators of hydrophytic vegetation and wetland hydrology must be present, unless disturbed or problematic.

Restrictive Layer (if observed):

Type: old riprap (boulders/cobbles)

Depth (inches): 8+

Hydric Soil Present? **Yes** X **No** ___

Remarks:

Soil sample allowed to dry to moist condition for inspection of redox features. No redox features were identified; however, soils are naturally problematic and assumed hydric because hydrology and vegetation criteria are satified. Data form is revised from Northcentral and Northeast Regional Supplement Version 2.0 to reflect the NRCS Field Indicators of Hydric Soils version 7.0 March 2013 Errata. (http://soils.usda.gov/use/hydric)

WETLAND DETERMINATION DATA FORM – Northcentral and Northeast Region

Project/Site: Grand River Whitewater Restoration Project City/County: Kent Sampling Date: 6/12/14

Applicant/Owner: City of Grand Rapids State: MI Sampling Point: D7

Investigator(s): Travis Morse Section, Township, Range:

Landform (hillside, terrace, etc.): terrace Local relief (concave, convex, none): concave Slope (%): 0-2

Subregion (LRR or MLRA): LRR L Lat: 42.96851359 Long: -85.6742455 Datum: NAD 83

Soil Map Unit Name: Urban Land NWI classification: R2UBH

Are climatic / hydrologic conditions on the site typical for this time of year? Yes x No ____ (If no, explain in Remarks.)

Are Vegetation ____, Soil ____, or Hydrology ____ significantly disturbed? Are "Normal Circumstances" present? Yes x No ____

Are Vegetation ____, Soil ____, or Hydrology ____ naturally problematic? (If needed, explain any answers in Remarks.)

SUMMARY OF FINDINGS – Attach site map showing sampling point locations, transects, important features, etc.

Hydrophytic Vegetation Present?	Yes X	No ____	**Is the Sampled Area**	
Hydric Soil Present?	Yes x	No ____	**within a Wetland?**	**Yes** X **No** ____
Wetland Hydrology Present?	Yes X	No ____	If yes, optional Wetland Site ID:	

Remarks: (Explain alternative procedures here or in a separate report.)

The community is located ~20' below the walkway/seawall. No access to ground level except for from river. Soil is assumed hydric based on position below OHWM. Soils were evaluated against data recorded at similar landscape postiion (e.g., D2)..

HYDROLOGY

Wetland Hydrology Indicators:

Primary Indicators (minimum of one is required; check all that apply)

- ____ Surface Water (A1)
- ____ High Water Table (A2)
- ____ Saturation (A3)
- ____ Water Marks (B1)
- x Sediment Deposits (B2)
- x Drift Deposits (B3)
- ____ Algal Mat or Crust (B4)

Surface Water Present?	Yes ____ No x	Depth (inches):	
Water Table Present?	Yes ____ No ____	Depth (inches):	?
Saturation Present? (includes capillary fringe)	Yes ____ No ____	Depth (inches):	?

Wetland Hydrology Present? **Yes** X **No** ____

Describe Recorded Data (stream gauge, monitoring well, aerial photos, previous inspections), if available:

Canopy cover on aerials. Anecdotal evidence: Client says area is frequently under water.

Remarks:

Rain within past 24 hours. Silt lines on tree bark. Debris piled against upstream side of rocks and trees. No access to dig soil pit. Geomorphic Position is an inappropriate indicator due to the rapidly permeable substrate and association to active drainageway.

VEGETATION – Use scientific names of plants. Sampling Point: D7

Tree Stratum (Plot size: 30' r modified)	Absolute % Cover	Dominant Species?	Indicator Status

Field Observations:

Surface Water Present?	Yes ____	No x	Depth (inches): ____
Water Table Present?	Yes ____	No x	Depth (inches): ____
Saturation Present? (includes capillary fringe)	Yes ____	No x	Depth (inches): ____

Wetland Hydrology Present? **Yes** ____ **No** x

Describe Recorded Data (stream gauge, monitoring well, aerial photos, previous inspections), if available:

Remarks:
Rain within past 24 hours. Microtopographic relief over ~30% of the surface area (relief 8 inches above the base soil level). Uneven topography resulting from rocks, logs, and other debris and really not indicative of hydrology. Therefore, D4 is inappropriate indicator at this location.

VEGETATION – Use scientific names of plants. Sampling Point: D7

Tree Stratum (Plot size: 30' r)	Absolute % Cover	Dominant Species?	Indicator Status

[3]Indicators of hydrophytic vegetation and wetland hydrology must be present, unless disturbed or problematic.

Restrictive Layer (if observed):

Type: _____

Depth (inches): _____

Hydric Soil Present? **Yes** ___ **No** x

Remarks:

Sandy fluvial deposits are a naturally problematic condition; however, the vegetation and hydrology criteria are not met. Data form is revised from Northcentral and Northeast Regional Supplement Version 2.0 to reflect the NRCS Field Indicators of Hydric Soils version 7.0 March 2013 Errata. (http://soils.usda.gov/use/hydric)

WETLAND DETERMINATION DATA FORM – Northcentral and Northeast Region

Project/Site: Grand River Whitewater Restoration Project City/County: Kent Sampling Date: 6/13/14

Applicant/Owner: City of Grand Rapids State: MI Sampling Point: D9

Investigator(s): Travis Morse Section, Township, Range:

Landform (hillside, terrace, etc.): river bank Local relief (concave, convex, none): convex Slope (%): 0-2

Subregion (LRR or MLRA): LRR L Lat: 42.98981028 Long: -85.67196484 Datum: NAD 83

Soil Map Unit Name: Urban Land NWI classification: R2UBH

Are climatic / hydrologic conditions on the site typical for this time of year? Yes x No ____ (If no, explain in Remarks.)

Are Vegetation ____, Soil ____, or Hydrology ____ significantly disturbed? Are "Normal Circumstances" present? Yes x No ____

Are Vegetation ____, Soil x, or Hydrology ____ naturally problematic? (If needed, explain any answers in Remarks.)

SUMMARY OF FINDINGS – Attach site map showing sampling point locations, transects, important features, etc.

Hydrophytic Vegetation Present?	Yes X	No ____	**Is the Sampled Area**	
Hydric Soil Present?	Yes X	No ____	**within a Wetland?**	**Yes** X **No** ____
Wetland Hydrology Present?	Yes X	No ____	If yes, optional Wetland Site ID:	

Remarks: (Explain alternative procedures here or in a separate report.)
sandy soils, fluvial deposits

HYDROLOGY

Wetland Hydrology Indicators:

Primary Indicators (minimum of one is required; check all that apply)

- ____ Surface Water (A1)
- ____ High Water Table (A2)
- ____ Saturation (A3)
- x Water Marks (B1)
- x Sediment Deposits (B2)
- x Drift Deposits (B3)
- ____ Algal Mat or Crust (B4)
- ____ Iron Deposits (B5)
- ____ Inundation Visible on Aerial Imagery (B7)
- ____ Sparsely Vegetated Concave Surface (B8)
- x Water-Stained Leaves (B9)
- ____ Aquatic Fauna (B13)
- ____ Marl Deposits (B15)
- ____ Hydrogen Sulfide Odor (C1)
- ____ Oxidized Rhizospheres on Living Roots (C3)
- ____ Presence of Reduced Iron (C4)
- ____ Recent Iron Reduction in Tilled Soils (C6)
- ____ Thin Muck Surface (C7)
- ____ Other (Explain in Remarks)

Secondary Indicators (minimum of two required)

- ____ Surface Soil Cracks (B6)
- ____ Drainage Patterns (B10)
- ____ Moss Trim Lines (B16)
- ____ Dry-Season Water Table (C2)
- ____ Crayfish Burrows (C8)
- ____ Saturation Visible on Aerial Imagery (C9)
- ____ Stunted or Stressed Plants (D1)
- ____ Geomorphic Position (D2)
- ____ Shallow Aquitard (D3)
- ____ Microtopographic Relief (D4)
- X FAC-Neutral Test (D5)

Field Observations:

Surface Water Present?	Yes ____	No x	Depth (inches): ____
Water Table Present?	Yes ____	No x	Depth (inches): ____
Saturation Present? (includes capillary fringe)	Yes ____	No x	Depth (inches): ____

Wetland Hydrology Present? **Yes** X **No** ____

Describe Recorded Data (stream gauge, monitoring well, aerial photos, previous inspections), if available:

Remarks:
Rain again; within past 24 hours. Near fringe of river. Otter midden in hollow log; several discarded mussel shales (unkown spp.).

VEGETATION – Use scientific names of plants. Sampling Point: D9

Tree Stratum (Plot size: 30' r)	Absolute % Cover	Dominant Species?	Indicator Status
1. *Salix nigra*	40	Yes	OBL
2. *Acer saccharinum*	20	Yes	FACW
3. *Fraxinus pennsylvanica*	20	Yes	FACW
4. *Ulmus americana*	10	No	FACW
5.			
6.			
7.			
	90	=Total Cover	
Sapling/Shrub Stratum (Plot size: 15' r)			
1. *Salix nigra*	10	Yes	OBL
2.			
3.			
4.			
5.			
6.			
7.			
	10	=Total Cover	
Herb Stratum (Plot size: 5' r)			
1. *Lysimachia nummularia*	25	Yes	FACW
2. *Carex cristatella*	20	Yes	FACW
3.			
4.			
5.			
6.			
7.			
8.			
9.			
10.			
11.			
12.			
	45	=Total Cover	
Woody Vine Stratum (Plot size: 30' r modified)			
1. *Vitis riparia*	3	No	FAC
2.			
3.			
4.			
	3	=Total Cover	

Dominance Test worksheet:

Number of Dominant Species That Are OBL, FACW, or FAC: 6 (A)

Total Number of Dominant Species Across All Strata: 6 (B)

Percent of Dominant Species That Are OBL, FACW, or FAC: 100.0% (A/B)

Prevalence Index worksheet:

Total % Cover of:		Multiply by:	
OBL species	50	x 1 =	50
FACW species	95	x 2 =	190
FAC species	3	x 3 =	9
FACU species	0	x 4 =	0
UPL species	0	x 5 =	0
Column Totals:	148 (A)		249 (B)

Prevalence Index = B/A = 1.68

Hydrophytic Vegetation Indicators:

___ 1 - Rapid Test for Hydrophytic Vegetation

X 2 - Dominance Test is >50%

x 3 - Prevalence Index is ≤3.0[1]

___ 4 - Morphological Adaptations[1] (Provide supporting data in Remarks or on a separate sheet)

___ Problematic Hydrophytic Vegetation[1] (Explain)

[1]Indicators of hydric soil and wetland hydrology must be present, unless disturbed or problematic.

Definitions of Vegetation Strata:

Tree – Woody plants 3 in. (7.6 cm) or more in diameter at breast height (DBH), regardless of height.

Sapling/shrub – Woody plants less than 3 in. DBH and greater than or equal to 3.28 ft (1 m) tall.

Herb – All herbaceous (non-woody) plants, regardless of size, and woody plants less than 3.28 ft tall.

Woody vines – All woody vines greater than 3.28 ft in height.

Hydrophytic Vegetation Present? **Yes** X **No** ___

Remarks: (Include photo numbers here or on a separate sheet.)

Sagittaria peltatum immediately outside of sample. Bark abrasion evident on willows - perhaps boat encounter or ice scour.

SOIL

Sampling Point: D9

Profile Description: (Describe to the depth needed to document the indicator or confirm the absence of indicators.)

Depth (inches)	Matrix Color (moist)	Matrix %	Redox Features Color (moist)	Redox Features %	Redox Features Type[1]	Redox Features Loc[2]	Texture	Remarks
0-6	10YR 2/1	100					Sandy	~90% masked, many fine roots, sandy loam
6-16	10YR 2/1	100					Sandy	sandy loam few OM. Sand grains visible

[1]Type: C=Concentration, D=Depletion, RM=Reduced Matrix, CS=Covered or Coated Sand Grains. [2]Location: PL=Pore Lining, M=Matrix.

Hydric Soil Indicators:

- ___ Histosol (A1)
- ___ Histic Epipedon (A2)
- ___ Black Histic (A3)
- ___ Hydrogen Sulfide (A4)
- ___ Stratified Layers (A5)
- ___ Depleted Below Dark Surface (A11)
- ___ Thick Dark Surface (A12)
- ___ Sandy Mucky Mineral (S1)
- ___ Sandy Gleyed Matrix (S4)
- ___ Sandy Redox (S5)
- ___ Stripped Matrix (S6)
- x Dark Surface (S7)
- ___ Polyvalue Below Surface (S8) (**LRR R, MLRA 149B**)
- ___ Thin Dark Surface (S9) (**LRR R, MLRA 149B**)
- ___ High Chroma Sands (S11) (**LRR K, L)**
- ___ Loamy Mucky Mineral (F1) (**LRR K, L**)

At Golder Associates we strive to be the most respected global group of companies specializing in ground engineering and environmental services. Employee owned since our formation in 1960, we have created a unique culture with pride in ownership, resulting in long-term organizational stability. Golder professionals take the time to build an understanding of client needs and of the specific environments in which they operate. We continue to expand our technical capabilities and have experienced steady growth with employees now operating from offices located throughout Africa, Asia, Australasia, Europe, North America and South America.

1.0 Introduction

Grand Rapids Whitewater has proposed improvements along an urban reach of the Grand River in the City of Grand Rapids, Kent County, Michigan. In 2014, the project engineer, River Restoration, retained Golder Associates, Inc. (Golder) to delineate wetlands within the project area to determine project impacts to regulated wetlands under Section 404 of the federal Clean Water Act and Part 303 of Michigan's Natural Resources and Environmental Protection Act (NREPA). River Restoration has engaged the Michigan Department of Environmental Quality (MDEQ) regarding the proposed project, and the MDEQ has assigned a project file number of 11-41-0105-P.

Golder completed a draft wetland delineation report in 2014 that identified twelve wetland areas totaling 3.09 acres within the 13.25-acre Grand River Whitewater Restoration Project site (Golder, 2014). The twelve wetlands were located within nine areas of investigation (IA 1 through IA 9), extending from the Fulton Street bridge north to approximately 0.45 mile north of the Leonard Street bridge. On December 11, 2014, MDEQ staff inspected the flagged wetland boundaries and discussed the draft report with Golder staff. In a letter dated January 14, 2015 (Appendix 1), MDEQ staff confirmed the delineated wetland boundaries located above the river's ordinary high-water mark (OHWM). The letter also states most of the delineated wetlands are located below the OHWM.

Redelineation of site wetlands is required to obtain an MDEQ/U.S. Environmental Protection Agency (USEPA) Joint Permit for proposed river and wetland impacts, because Golder's wetland delineation occurred more than three years previously. River Restoration requested Fishbeck, Thompson, Carr & Huber, Inc. (FTCH) to complete wetland delineation of the first phase of the proposed river restoration project. The area impacted by Phase 1 extends from the Fulton Street bridge north to approximately 100 feet north of westbound Interstate I-196. This area of investigation corresponds to Golder's Investigation Areas IA 1 through IA 4. FTCH surveyed both sides of the Grand River within this area and evaluated the wetland status at seven of Golder's identified wetlands (W6 through W12).

This report summarizes the results of FTCH's wetland investigation. It is intended to be a supplement to Golder's 2014 report, which contained resource maps and in-office information not replicated in this report. The intent of this report is to provide current wetland boundaries to accurately determine wetland impacts resulting from the river restoration project and assist in making design choices that avoid and minimize wetland impacts.

2.0 Project Location and Description

The area of investigation extends approximately 0.7 mile along the Grand River, as indicated on Figure 1. Within this area, river frontage contained seawalls, armored banks, and vegetated buffer (both natural and managed). The area of investigation is located within the heart of downtown Grand Rapids; the surrounding landscape is highly developed and urbanized. Sidewalks, pedestrian pathways, and boardwalks were located within close proximity of the river edge throughout most of the area of investigation. Riverbanks were steep in some areas and contained evidence of historic fill (i.e., bricks, concrete slabs, and boulders).

3.0 Methods

FTCH conducted the field investigation on December 18, 2018. The river was not at flood stage and water levels were approximately 2 feet below a boardwalk extending over the east edge of the river.

The investigation was conducted in a manner consistent with the 1987 *Corps of Engineers Wetlands Delineation Manual* and 2012 *Regional Supplement to the Corps of Engineers Wetland Delineation Manual: Northcentral and Northeast Region* (Version 2). The wetlands identification and delineation procedures outlined in these manuals require evaluation of site vegetation, soils, and hydrologic characteristics. Dominant wetland vegetation, hydric soil, and wetland hydrology must all be present for an area to be classified as a wetland. Hydrophytic vegetation decisions are based on the wetland indicator status of species that are dominant in the plant community. Wetland indicator statuses were obtained from the *State of Michigan 2016 Wetland Plant List* (Lichvar et.al.). Species with indicator statuses of obligate wetland (OBL), facultative wetland (FACW), and facultative (FAC) are considered wetland species, while species with indicator statuses of facultative upland (FACU) and upland (UPL) are considered upland species. FAC species are also commonly present in upland plant communities.

A U.S. Army Corps of Engineers Wetland Determination Data Form was completed to describe site vegetation, soil, and hydrology at each sampling location (Appendix 2). FTCH flagged wetland boundaries with pink ribbon and surveyed the flags with a handheld GPS unit with submeter accuracy. The wetland boundaries are noted as solid fuchsia-colored lines on Figure 1. The approximate outer wetland boundary along the river's edge was estimated based upon the aerial photograph and is noted as a dashed purple line on Figure 1.

4.0 Results and Discussion

The field investigation was conducted on a sunny day with air temperatures ranging from 20°F to 38°F. The investigation was conducted weeks after a killing frost, which impaired identification of vegetation. The ground was not covered in snow, but it was frozen at some locations, which impeded examination of soil at sampling point SP-8.

Identified wetlands were numbered in a manner consistent with the Golder investigation and are discussed below. Photographs of each area are included in Appendix 3.

Wetland 6

The Golder report indicated Wetland W6 extended north, approximately 400 feet from Interstate I-196 on the west side of the Grand River, and it encompassed 0.15 acre of scrub-shrub wetland. FTCH investigated approximately 100 feet north from the highway, in accordance with the northern limit of Phase 1. No wetlands were observed along the river's edge in this area. The bank contained boulders and riprap (see the photograph in Appendix 3). Google Earth® aerial photographs indicate a partial dam was present halfway across the river in this area in September 2017. It was constructed to facilitate work on I-196. The dam was removed by September 2018. The boulders currently present at the south end of former Wetland W6 corresponds to the northern limit of the embankment.

Wetland 7

Wetland 7 is located on the west bank on the Grand River, between Interstate I-196 and Bridge Street. The associated steep bank contained an array of seawalls and hard armoring consisting of boulders and slabs of broken concrete. In some areas, boulders extend to the water's edge, with wetland vegetation growing around them. Wetland sampling point SP-7 was evaluated at the north end of Wetland 7 on a flood bench relatively free

of boulders. A test pit excavated to a depth of 17 inches verified the presence of wetland hydrology (soil saturation and the water table was within the surface foot) and wetland soil (prominent redox features). The dominant vegetation observed in the vicinity of SP-7 was reed canarygrass (*Phalaris arundinacea*, FACW). Other common species observed in Wetland 7 were purple loosestrife (*Lythrum salicaria*, OBL), riverbank grape (*Vitis riparia*, FAC), and red-osier dogwood (*Cornus alba*, FACW). FTCH flagged Wetland 7's boundaries with pink ribbons labelled 7-1 through 7-12.

Wetland 8

Wetland 8 consisted of floodplain forest on the west side of the Grand River, north and northeast of Ah-Nab-Awen Park. Golder's 2014 wetland delineation placed the eastern wetland boundary into the Grand River in some areas, thus overestimating the extent of this wetland. A flood bench containing forested wetland dominated with eastern cottonwood trees (*Populus deltoides*, FAC) was present along the river edge. Fluvial deposits of sand and gravel were observed on the ground surface throughout the flood bench. The adjacent slope steeply graded up 10 to 15 feet to the top-of-bank. The bank contained boulders and large blocks of concrete.

Sampling point SP-8 was evaluated on the flood bench near the south end of Wetland 8. Soil excavation was impeded by frozen ground at a depth of one inch. Surface soil consisted of a shallow layer of fluvial sand and gravel over darker topsoil consisting of sandy loam. The USACE recognizes fluvial deposits within a floodplain as a problematic hydric soil because they often lack hydric soil indicators. FTCH assumed the frozen soil indicated the presence of groundwater. This depth was consistent with the corresponding level of water in the adjacent river.

FTCH flagged the wetland boundary with pink ribbons labelled 8-1 through 8-10. A short seawall constructed from rocks and/or concrete chunks was located between flags 8-5 and 8-6.

Wetland 9

Wetland 9 is located on the east side of the river, directly west of the DeVos Place Convention Center and Performance Hall. An approximately 20-foot-high seawall is present along the river's edge throughout this area. The wall curves to the east, forming a cove. The only access to this area is from the river.

Sediment has accumulated within the cove, resulting in two distinct plant communities: floodplain forest in a relatively flat area along the river's edge, and a scrub-shrub plant community on an embankment next to the seawall (see photograph of Wetland 9 view from the west). The top-of-bank was approximately 5 feet above the floodplain elevation; no wetland hydrology indicators were observed on the embankment. The wetland boundary appeared to be at the toe of the embankment, which corresponded to the easternmost location of mature floodplain trees. The north and south limits of Wetland 9 were surveyed from a walkway overlooking the wetland. These points also correlated to the approximate wetland boundary. Wetland occupied approximately the western half of the area filled with sediment within the cove.

Sampling point SP-9 was located within the floodplain forest, approximately 25 feet west of the pedestrian pathway guardrail, as noted on Figure 1. Data included on the wetland determination data form was obtained visually from the pathway directly east of SP-9.

Wetland 10

Wetland 10 is located on the west side of the river, north of the Gillett Bridge and east of the Gerald R. Ford Presidential Museum. Two scrub-shrub wetlands were identified at the toe of a heavy riprap, armored bank in this area. The wetlands were separated by a concrete culvert with wing walls. The dominant species in the wetland were sandbar willow (*Salix exigua*, OBL) and reed canarygrass. FTCH was unable to excavate a soil pit at

sampling point SP-10 due to the presence of rock associated with the armored bank. Surface soil saturation was visible at SP-10, verifying wetland hydrology. This wetland has expanded to the north since Golder's 2014 wetland delineation.

FTCH flagged the wetland boundaries with pink ribbons labelled 10-1 through 10-3 for the southern wetland and 10-4 through 10-9 for the northern wetland.

Wetland 11

The Golder report indicated Wetland W11 was located on the west side of the Grand River, between the Gillett and Pearl Street Bridges, and consisted of 0.11 acre of floodplain forest. In this area, FTCH observed new sidewalk, concrete steps to the river's edge, and an armored bank containing heavy riprap (see photographs in Appendix 3). No wetlands were observed in this area. Google Earth® aerial photographs indicate site modifications were implemented between September 9, 2017, and September 22, 2018.

Wetland 12

Wetland 12 was located on the east side of the river, just north of the Fulton Street bridge. The wetland was confined to the toe of a steep, armored bank and primarily consisted of eastern cottonwood trees (*Populus deltoides*, FAC). The wetland was typically 2 to 3 feet wide along the river's edge. FTCH was unable to dig a test pit at sampling point SP-12 due to the presence of concrete and rocks associated with the embankment. The presence of hydric soil was assumed because SP-12 was located below the OHWM. Wetland hydrology was confirmed because surface water was at a similar elevation as SP-12 and within two feet of the sample plot. FTCH flagged the wetland boundaries with pink ribbons labelled 12-1 through 12-6.

5.0 Conclusions

According to Michigan's NREPA, Act 451, Section 30301(d), wetlands "contiguous to the Great Lakes or Lake St. Clair, an inland lake or pond, or a river or stream" or "more than 5 acres in size" are regulated by the State of Michigan. FTCH has delineated wetland boundaries for four wetlands contiguous to the Grand River within the area of investigation (Wetlands 7, 8, 10, and 12). FTCH verified the presence of a fifth wetland (Wetland 9) and, due to access restrictions, approximated its wetland boundaries based on remote field observation. Table 1 below summarizes the area and linear length of the identified wetlands. All the identified wetlands are regulated by the federal Clean Water Act and Part 303 of the NREPA because they are contiguous to the Grand River.

Table 1 – Summary of Delineated Wetlands
Rapids Restoration Project - Phase 1
Grand Rapids, Michigan

Wetland	Wetland Type	Size (square feet)	Size (acre)	Length (linear feet)
7	Emergent/scrub-shrub	5308	0.122	469
8	Floodplain forest	2170	0.050	385
9	Floodplain forest	2316	0.053	256
10	Scrub-shrub wetland	705	0.016	127
12	Floodplain forest	1503	0.035	200

FTCH verified that two wetlands identified by Golder in 2014 are no longer present (the south end of Wetland 6 and Wetland 11). These wetlands were removed during construction activities occurring along the river in 2017 or early 2018.

RICK SNYDER
GOVERNOR

DAN WYANT
DIRECTOR

January 14, 2015

VIA E-MAIL

Ms. Hattie Johnson
RiverRestoration
P.O. Box 245
Carbondale, Colorado 81623

Dear Ms. Johnson:

In follow-up to our previous discussion, the Department of Environmental Quality (DEQ), Water Resources Division (WRD) has reviewed the draft wetland delineation you provided. On December 11, 2014, Ms. Amanda Whitscell, Grand Rapids District Office, WRD, and I reviewed on-site the delineated wetlands that were mapped and discussed in the Golder Associates, Inc. draft wetland delineation report (October 2014).

According to the draft report and our on-site review, the majority of the total mapped wetland area indicated in the report appears to occur below the ordinary high water line of the Grand River. Because of this, we focused on the landward (outside the river) boundaries of the wetlands delineation within the project area and concur that this landward boundary is accurate.

If you have any questions, please contact me at 517-284-5534; gyekisk@michigan.gov; or DEQ, P.O. Box 30458, Lansing, Michigan 48909-7958.

Sincerely,

Keto Gyekis

Wetland Hydrology Present?	Yes ◉ No ○		

Remarks: (Explain alternative procedures here or in a separate report.)

Hydrology

Wetland Hydrology Indicators:

Primary Indicators (minimum of one required; check all that apply)

- ☐ Surface Water (A1)
- ☑ High Water Table (A2)
- ☑ Saturation (A3)
- ☐ Water Marks (B1)
- ☑ Sediment Deposits (B2)
- ☐ Drift deposits (B3)
- ☐ Algal Mat or Crust (B4)
- ☐ Iron Deposits (B5)
- ☐ Inundation Visible on Aerial Imagery (B7)
- ☐ Sparsely Vegetated Concave Surface (B8)
- ☐ Water-Stained Leaves (B9)
- ☐ Aquatic Fauna (B13)
- ☐ Marl Deposits (B15)
- ☐ Hydrogen Sulfide Odor (C1)
- ☐ Oxidized Rhizospheres along Living Roots (C3)
- ☐ Presence of Reduced Iron (C4)
- ☐ Recent Iron Reduction in Tilled Soils (C6)
- ☐ Thin Muck Surface (C7)
- ☐ Other (Explain in Remarks)

Secondary Indicators (minimum of 2 required)

- ☐ Surface Soil Cracks (B6)
- ☐ Drainage Patterns (B10)
- ☐ Moss Trim Lines (B16)
- ☐ Dry Season Water Table (C2)
- ☐ Crayfish Burrows (C8)
- ☐ Saturation Visible on Aerial Imagery (C9)
- ☐ Stunted or Stressed Plants (D1)
- ☐ Geomorphic Position (D2)
- ☐ Shallow Aquitard (D3)
- ☐ Microtopographic Relief (D4)
- ☑ FAC-neutral Test (D5)

Field Observations:

Surface Water Present?	Yes ○ No ◉	Depth (inches):	0	
Water Table Present?	Yes ◉ No ○	Depth (inches):	9	
Saturation Present? (includes capillary fringe)	Yes ◉ No ○	Depth (inches):	6	**Wetland Hydrology Present?** Yes ◉ No ○

Describe Recorded Data (stream gauge, monitoring well, aerial photos, previous inspections), if available:

Remarks:

Depositional sand and gravel observed in spots within Wetland 7. Boulders have been placed to the edge of water to stabilize this area. Wetland boundary was flagged with pink ribbon labelled 7-1 through 7-12.

- ☐ Depleted Below Dark Surface (A11)
- ☐ Thick Dark Surface (A12)
- ☐ Sandy Muck Mineral (S1)
- ☐ Sandy Gleyed Matrix (S4)
- ☑ Sandy Redox (S5)
- ☐ Stripped Matrix (S6)
- ☐ Dark Surface (S7) (LRR R, MLRA 149B)
- ☐ Polyvalue Below Surface (S8) (LRR R, MLRA 149B)
- ☐ Thin Dark Surface (S9) (LRR R, MLRA 149B)
- ☐ Loamy Mucky Mineral (F1) LRR K, L)
- ☐ Loamy Gleyed Matrix (F2)
- ☑ Depleted Matrix (F3)
- ☐ Redox Dark Surface (F6)
- ☐ Depleted Dark Surface (F7)
- ☐ Redox Depressions (F8)

Indicators for Problematic Hydric Soils : [3]

- ☐ 2 cm Muck (A10) (LRR K, L, MLRA 149B)
- ☐ Coast Prairie Redox (A16) (LRR K, L, R)
- ☐ 5 cm Mucky Peat or Peat (S3) (LRR K, L, R)
- ☐ Dark Surface (S7) (LRR K, L, M)
- ☐ Polyvalue Below Surface (S8) (LRR K, L)
- ☐ Thin Dark Surface (S9) (LRR K, L)
- ☐ Iron-Manganese Masses (F12) (LRR K, L, R)
- ☐ Piedmont Floodplain Soils (F19) (MLRA 149B)
- ☐ Mesic Spodic (TA6) (MLRA 144A, 145, 149B)
- ☐ Red Parent Material (F21)
- ☐ Very Shallow Dark Surface (TF12)
- ☐ Other (Explain in Remarks)

[3] Indicators of hydrophytic vegetation and wetland hydrology must be present, unless disturbed or problematic.

Restrictive Layer (if observed):

Type: _____

Depth (inches): _____

Hydric Soil Present? Yes ◉ No ○

Remarks:

WETLAND DETERMINATION DATA FORM - Northcentral and Northeast Region

Project/Site: Grand River Restoration **City/County:** Grand Rapids/Kent **Sampling Date:** 18-Dec-18

Applicant/Owner: River Restoration **State:** Michigan **Sampling Point:** SP-8

Investigator(s): Elise Tripp **Section, Township, Range:** S. 25 T. 7N R. 12W

Landform (hillslope, terrace, etc.): Floodplain **Local relief (concave, convex, none):** concave **Slope:** 5.0 % / 2.9 °

Subregion (LRR or MLRA): LRR L **Lat.:** 42.969061 **Long.:** -85.676020 **Datum:** WGS84

Soil Map Unit Name: Urban land **NWI classification:** R2UBH

Are climatic/hydrologic conditions on the site typical for this time of year? Yes ◉ No ○ **(If no, explain in Remarks.)**

Are Vegetation ☐ **, Soil** ☐ **, or Hydrology** ☐ **significantly disturbed?** **Are "Normal Circumstances" present?** Yes ◉ No ○

Are Vegetation ☐ **, Soil** ☑ **, or Hydrology** ☐ **naturally problematic?** **(If needed, explain any answers in Remarks.)**

Summary of Findings - Attach site map showing sampling point locations, transects, important features, etc.

Hydrophytic Vegetation Present?	Yes ◉ No ○	**Is the Sampled Area within a Wetland?**	Yes ◉ No ○
Hydric Soil Present?	Yes ◉ No ○		
Wetland Hydrology Present?	Yes ◉ No ○		

Remarks: (Explain alternative procedures here or in a separate report.)

Fluvial deposits wtihin a floodplain are a problematic hydric soil. Hydric soil is assumed because groundwater was encountered at a depth of 1 inch. The wetland boundary was flagged with flags 8-1 through 8-10.

Hydrology

Wetland Hydrology Indicators:

Primary Indicators (minimum of one required; check all that apply)

- ☐ Surface Water (A1)
- ☑ High Water Table (A2)
- ☑ Saturation (A3)
- ☐ Water Marks (B1)
- ☑ Sediment Deposits (B2)
- ☐ Drift deposits (B3)
- ☐ Algal Mat or Crust (B4)
- ☐ Iron Deposits (B5)
- ☐ Inundation Visible on Aerial Imagery (B7)
- ☑ Sparsely Vegetated Concave Surface (B8)
- ☐ Water-Stained Leaves (B9)
- ☐ Aquatic Fauna (B13)
- ☐ Marl Deposits (B15)
- ☐ Hydrogen Sulfide Odor (C1)
- ☐ Oxidized Rhizospheres along Living Roots (C3)
- ☐ Presence of Reduced Iron (C4)
- ☐ Recent Iron Reduction in Tilled Soils (C6)
- ☐ Thin Muck Surface (C7)
- ☐ Other (Explain in Remarks)

Secondary Indicators (minimum of 2 required)

- ☐ Surface Soil Cracks (B6)
- ☐ Drainage Patterns (B10)
- ☐ Moss Trim Lines (B16)
- ☐ Dry Season Water Table (C2)
- ☐ Crayfish Burrows (C8)
- ☐ Saturation Visible on Aerial Imagery (C9)
- ☐ Stunted or Stressed Plants (D1)
- ☐ Geomorphic Position (D2)
- ☐ Shallow Aquitard (D3)
- ☐ Microtopographic Relief (D4)
- ☑ FAC-neutral Test (D5)

Field Observations:

Surface Water Present?	Yes ○	No ◉	Depth (inches):	
Water Table Present?	Yes ◉	No ○	Depth (inches): 1	**Wetland Hydrology Present?** Yes ◉ No ○
Saturation Present? (includes capillary fringe)	Yes ◉	No ○	Depth (inches): 0	

Describe Recorded Data (stream gauge, monitoring well, aerial photos, previous inspections), if available:

Remarks:

Silt lines on tree bark. Concave relief on floodplain, next to steep bank 10 to 15 feet high.

VEGETATION - Use scientific names of plants

Summary of Findings - Attach site map showing sampling point locations, transects, important features, etc.

Hydrophytic Vegetation Present?	Yes ◉ No ○	**Is the Sampled Area within a Wetland?**	Yes ◉ No ○
Hydric Soil Present?	Yes ◉ No ○		
Wetland Hydrology Present?	Yes ◉ No ○		

Remarks: (Explain alternative procedures here or in a separate report.)

Wetland was not accessible except from river. The plant community is approximately 20 feet below the walkway/seawall. Soil is assumed hydric based on position below the OHWM. Grade sloped down from seawall to the edge of water. Wetland boundary is approximately halfway between the seawall and the river's edge.

Hydric Soil Present?	Yes ◉ No ○		
Wetland Hydrology Present?	Yes ◉ No ○		

Remarks: (Explain alternative procedures here or in a separate report.)

Soil could not be evaluated due to the prevalence of rock and boulders on the ground surface. Rock was 1 to 3 feet in diameter. Wetland determination was based on observed vegetation and hydrology indicators.Wetland 10 consisted to two segments. The southern segment consisted of wetland flags 10-1 to 10-3. The northern segment consisted of wetland flags 10-4 through 10-9.

[3] Indicators of hydrophytic vegetation and wetland hydrology must be present, unless disturbed or problematic.

Restrictive Layer (if observed):

Type: Rock

Depth (inches): 0

Hydric Soil Present? Yes ◉ No ○

Remarks:

Soil refusal due to rock and boulders at ground surface. Assume hydric soil is present due to location below the OHWM.

WETLAND DETERMINATION DATA FORM - Northcentral and Northeast Region

Project/Site: Grand River Restoration **City/County:** Grand Rapids/Kent **Sampling Date:** 18-Dec-18

Applicant/Owner: River Restoration **State:** Michigan **Sampling Point:** SP-12

Investigator(s): Elise Tripp **Section, Township, Range:** S. 25 T. 7N R. 12W

Landform (hillslope, terrace, etc.): Hillside **Local relief (concave, convex, none):** convex **Slope:** 20.0 % / 11.3 °

Subregion (LRR or MLRA): LRR L **Lat.:** 42.963821 **Long.:** -85.674937 **Datum:** WGS84

Soil Map Unit Name: Urban land **NWI classification:** R2UBH

Are climatic/hydrologic conditions on the site typical for this time of year? Yes ◉ No ○ **(If no, explain in Remarks.)**

Are Vegetation ☐ **, Soil** ☑ **, or Hydrology** ☐ **significantly disturbed?** **Are "Normal Circumstances" present?** Yes ○ No ◉

Are Vegetation ☐ **, Soil** ☐ **, or Hydrology** ☐ **naturally problematic?** **(If needed, explain any answers in Remarks.)**

Summary of Findings - Attach site map showing sampling point locations, transects, important features, etc.

Hydrophytic Vegetation Present?	Yes ◉ No ○	**Is the Sampled Area within a Wetland?**	Yes ◉ No ○
Hydric Soil Present?	Yes ◉ No ○		
Wetland Hydrology Present?	Yes ◉ No ○		

Remarks: (Explain alternative procedures here or in a separate report.)

Hillside is armored with a concrete/rock wall. Wetland is confined to the toe of slope at the edge of the river and is generally 2 to 3 feet wide. Could not excavate a test pit due to rock and concrete.Wetland boundary flagged with flags numbered 12-1 through 12-6.

Hydrology

Wetland Hydrology Indicators:

Primary Indicators (minimum of one required; check all that apply)

- ☑ Surface Water (A1)
- ☑ High Water Table (A2)
- ☑ Saturation (A3)
- ☐ Water Marks (B1)
- ☐ Sediment Deposits (B2)
- ☐ Drift deposits (B3)
- ☐ Algal Mat or Crust (B4)
- ☐ Iron Deposits (B5)
- ☐ Inundation Visible on Aerial Imagery (B7)
- ☐ Sparsely Vegetated Concave Surface (B8)
- ☐ Water-Stained Leaves (B9)
- ☐ Aquatic Fauna (B13)
- ☐ Marl Deposits (B15)
- ☐ Hydrogen Sulfide Odor (C1)
- ☐ Oxidized Rhizospheres along Living Roots (C3)
- ☐ Presence of Reduced Iron (C4)
- ☐ Recent Iron Reduction in Tilled Soils (C6)
- ☐ Thin Muck Surface (C7)
- ☐ Other (Explain in Remarks)

Secondary Indicators (minimum of 2 required)

- ☐ Surface Soil Cracks (B6)
- ☐ Drainage Patterns (B10)
- ☐ Moss Trim Lines (B16)
- ☐ Dry Season Water Table (C2)
- ☐ Crayfish Burrows (C8)
- ☐ Saturation Visible on Aerial Imagery (C9)
- ☐ Stunted or Stressed Plants (D1)
- ☐ Geomorphic Position (D2)
- ☐ Shallow Aquitard (D3)
- ☐ Microtopographic Relief (D4)
- ☐ FAC-neutral Test (D5)

Field Observations:

Surface Water Present?	Yes ◉ No ○	Depth (inches):	5
Water Table Present?	Yes ◉ No ○	Depth (inches):	0
Saturation Present? (includes capillary fringe)	Yes ◉ No ○	Depth (inches):	0

Wetland Hydrology Present? Yes ◉ No ○

Memo

TO: Tim Burkman, P.E. – City of Grand Rapids Engineer

FROM: Elise Hansen Tripp, PWS

DATE: October 18, 2023 PROJECT NO.: 180419

SUBJECT: Wetland Boundary Verification
Lower Reach of the Grand River, City of Grand Rapids, Michigan

On December 18, 2018, Fishbeck delineated wetlands along the banks of the Grand River from the Fulton Street bridge north to approximately 100 feet north of westbound Interstate I-196. The results of this investigation are summarized in Fishbeck's report titled, *Updated Wetland Delineation, Grand River Whitewater Restoration Project, City of Grand Rapids, Kent County, Michigan*, dated February 26, 2019. The Michigan Department of Environment, Great Lakes, and Energy (EGLE) considers wetland delineations valid for a period of three years. Amy Lounds of EGLE has requested that Fishbeck inspect wetlands within the area of investigation, verify the previously delineated wetland boundaries, and update the wetland boundaries, if needed.

Site wetlands were initially delineated by Golder Associates, Inc. (Golder) in 2014. Golder's wetland naming conventions were retained in Fishbeck's 2018 and 2023 investigations. Wetlands 6 through 12 are located within the area of investigation.

Fishbeck staff conducted the wetland verification on October 10, 2023, before a killing frost. Wetland boundaries surveyed in 2018 were located using Global Positioning System technology with submeter accuracy (Trimble R1 GNSS receiver). Site observations are summarized below. Figure 1 notes the area of investigation, verified wetland boundaries, and new delineated wetland boundaries. Photographs of site wetlands are located in Attachment 1.

Wetland 6 (Former)

The Golder report indicated Wetland 6 extended north, approximately 400 feet from Interstate I-196 on the west side of the Grand River, and it encompassed 0.15 acre of scrub-shrub wetland. No wetland was present in this area in 2018 due to prior construction and placement of boulders and riprap. Additionally, no wetland was observed in this area on October 10, 2023.

Wetland 7

Wetland 7 is located on the west bank on the Grand River, between Interstate I-196 and Bridge Street. Fishbeck made one adjustment to the wetland boundary on October 10, 2023: two wetland boundary flags labelled 7-1 and 7-2 were placed west of the 2018 wetland boundary at the south end of the wetland. The adjusted boundary is noted as a cyan line on Figure 1.

Wetland 8

Wetland 8 consisted of floodplain forest on the west side of the Grand River, north and northeast of Ah-Nab-Awen Park. Fishbeck verified the 2018 wetland boundary correlates to the current wetland boundary. This boundary is defined by rock embankments and low seawalls. No adjustments to the wetland boundary were made.

Wetland 9

Wetland 9 is located on the east side of the river, directly west of the DeVos Place Convention Center and Performance Hall. An approximately 20-foot-high seawall is present along the river's edge throughout this area. The wall curves to the east, forming a cove. The only access to this area is from the river. The north and south limits of Wetland 9 were surveyed from a walkway overlooking the wetland. These points also correlated to the approximate wetland boundary. Wetland occupied approximately the western half of the area filled with sediment within the cove. Fishbeck did not make any adjustments to the 2018 wetland boundary.

Wetland 10

Wetland 10 is located on the west side of the river, north of the Gillett Bridge and east of the Gerald R. Ford Presidential Museum. In 2018, this wetland consisted of two segments of scrub-shrub wetland separated by concrete culvert with wingwalls. By 2023, the gap between the wetland segments had filled with sandbar willow (*Salix exigua*), a wetland-ranked species. Therefore, Fishbeck extended the delineated wetland boundary across the gap, as indicated on Figure 1.

Wetland 11 (Former)

The Golder report indicated Wetland 11 was located on the west side of the Grand River, between the Gillett and Pearl Street Bridges, and consisted of 0.11 acre of floodplain forest. Fishbeck observed sidewalk, concrete steps to the river's edge, and an armored bank containing heavy riprap in 2018 and 2023. Saplings of woody species were established between the embankment's rocks by 2023. These plants consisted of both upland-ranked [northern catalpa (*Catalpa speciosa*, FACU) and staghorn sumac (*Rhus typhina*, FACU)] and wetland-ranked [silver maple (*Acer saccharinum*, FACW)] species. No distinct wetland edge was observed along the river in this area.

Wetland 12

Wetland 12 was located on the east side of the river, just north of the Fulton Street bridge. The wetland was confined to the toe of a steep, armored bank and primarily consisted of eastern cottonwood trees (*Populus deltoides*, FAC). In 2023, wetland continued north of the 2018 Wetland 12 limit as a narrow band of emergent and scrub-shrub wetland along the river's edge south of the Blue Bridge and west of the River's Edge Environmental Sculpture. The shoreline was armored with rock in this area. The shoreline was not armored with riprap, boulders, or seawall north of the Blue Bridge, and the ground in this area appeared unstable with extensive bare areas and varying amounts of emergent and scrub-shrub wetland. In some areas, wetland was confined to the water's edge and in other areas it extended east to the adjacent riverwalk sidewalk.

Wetland was not observed in this area during the 2014 and 2018 wetland delineations. Comparing topographic surveys conducted in 1990 and 2021 confirmed the ground surface has lowered approximately 2 to 3 feet due to erosion and river scour, creating a flood bench that supports wetland vegetation. Extensive bank destabilization has undercut the adjacent riverwalk sidewalk in some areas. In January 2023, EGLE issued permit number WRP036258 to the City of Grand Rapids to reconstruct the riverwalk and stabilize the shoreline with boulders and plugs of native species. Wetland 12 did not extend into the project reach during the 2018 delineation, which was submitted as part of the permit application for the recently permitted sidewalk repairs. The East River Edge Sidewalk Repair will involve the placement of fill in the newly delineated wetland. The River Restoration project will have no impacts in the expanded wetland footprint.

Fishbeck staff flagged the boundary of the recently developed wetland with pink survey ribbons labelled 12A-1 through 12A-14. The northern extent of this wetland ended at wetland flag 12A-14 at a rock embankment. Table 1 summarizes plant species observed within Wetland 12's emergent and scrub-shrub wetland. The expanded wetland boundary is noted on Figure 1.

Conclusions

According to Michigan's NREPA, Act 451, Section 30301(d), wetlands "contiguous to the Great Lakes or Lake St. Clair, an inland lake or pond, or a river or stream" or "more than 5 acres in size" are regulated by the State of Michigan. Fishbeck staff verified and delineated wetland boundaries for four wetlands contiguous to the Grand River within the area of investigation (Wetlands 7, 8, 10, and 12). Fishbeck staff verified the presence of a fifth wetland (Wetland 9) and, due to access restrictions, approximated its wetland boundaries based on remote field observation. Table 2 summarizes the updated area and linear length of the identified wetlands. All the identified wetlands are regulated by the federal Clean Water Act and Part 303 of the NREPA because they are contiguous to the Grand River.

Table 1. Plant Species Observed at Wetland 12 on October 10, 2023
Grand River Restoration, Phase 1, Grand Rapids, Michigan

Scientific Name	Common Name	Native?	W	Physiognomy
Acer saccharinum	Silver maple	Native	FACW	Tree

FIRE CHIEF

RONALD TENNANT
DEPUTY FIRE CHIEF

TODD VANDERWALL
DEPUTY FIRE CHIEF

March 18, 2021

Subject: Public Safety for a Restored River

To Whom It May Concern:

I have had the great pleasure of working alongside the team of City of Grand Rapids staff, Grand Rapids Whitewater and their cadre of river engineers to provide input into the design of a revitalized Grand River.

As the design has progressed, the Grand Rapids Fire Department River Rescue Team has been at the table providing input on the design and emergency response access needs (both during construction and after construction), and we have been actively planning for future river rescue needs.

Over several years, we have trained many of our team in advanced swift water rescue. We have trained 22 firefighters as Public Safety divers to support immediate rescue needs above and below the river surface. We are excited about the prospect of more people using the Grand River for recreation and are ready for any emergency rescue needs that may arise.

Sincerely,

John Lehman
Grand Rapids Fire Chief

Ottawa County Letter 5/7/2021

Ottawa County
Administrator's Office

Alan G. Vanderberg
County Administrator

John E. Shay
Deputy County Administrator

Regina L. MacMillan
Administrative Assistant

May 7, 2021

Mr. Steve Heacock
President and CEO
Grand Rapids Whitewater
120 Lyon Street NW
Grand Rapids, MI 49503

Dear Steve,

We are writing to comment upon your requirement to show that at least twenty percent of the benefits of the Grand Rapids Whitewater project accrue to agricultural land and communities.

As you know, Ottawa County is located immediately West of Kent County, downstream of the Grand River Restoration project in Grand Rapids and includes the mouth of the Grand River where it empties into Lake Michigan.

Ottawa County is composed of 17 townships, six cities and one village, with an area of 565 square miles. Only one of cities and six of the townships have a population of substantially more than 10,000. Thirty-eight (38%) percent of the County's land mass is farmland. Ottawa County leads all other Michigan counties in the production of turkeys, ornamental nursery crops, blueberries, and perennials.

Besides Lake Michigan beaches, there are 307 miles of rivers and streams, two state parks, and over 7,000 acres of county parks and open space lands for visitors to enjoy. Tourism is an important part of the Ottawa County economy. Each year this area welcomes millions of visitors to its vacation playground.

We are aware of the GRWW Project and have considered its potential impact on the river, land, and communities of Ottawa County, particularly the many farms and farming communities. Since fish, mussels, and insects do not recognize County lines, ecological improvements from the Project site will benefit the entire river downstream of the Project Site to Lake Michigan, much of which is in Ottawa County.

Every benefit of the Project also benefits the river downstream of the Project. The Project's many goals will improve stability and growth in fish population, improve spawning habitat, and provide better care and management of mussel species. Reintroduction of rapid-type habitat to the Grand River will not only benefit aquatic species, but it will also bring the Grand River closer to its natural state from the Project site to its terminus in Ottawa County. The benefits realized in the river itself impact the river shore, and the agricultural and rural land and communities abutting the river. Ottawa County's ecology will benefit greatly from the Project.

But the benefits are not just ecological. The Project, especially the revitalization of the rapids and removal of dangerous low-head dams, will encourage expanded public use of the river and further supports The Grand River Greenway Vision of connecting Grand Rapids and Grand Haven for residents and visitors to explore by foot, bike or kayak (via the Idema Explorers Trail an Grand River Heritage Water Trail). The enhancement of recreation opportunities such as paddling, rafting, tubing, and angling in the Grand River will allow our small cities and townships to further efforts to attract tourists to their hospitality businesses. In fact, Ottawa County Parks is already coordinating with partners in Kent County, including GRWW to ensure that the projects are complementary in their amenities, wayfinding, and marketing. These efforts are sure to grow in the future.

We state with confidence that at least twenty percent of the benefits of the Project will accrue to Ottawa County and the area downstream of the Project site.

Alan G. Vanderberg
Ottawa County Administrator

Jason Shamblin

Memo

To	Wendy Ogilvie
From	Heather Heater and Steve Koster
Date	16 April 2021
Reference	0476625
Subject	Suggested Approach to Assessment of Aquatic Benefits from the GRWW Project to Agricultural Areas

Concept:

Ecological benefits from the Project will be realized throughout the Grand River watershed, including the segment downstream of the Project. These benefits will include downstream fish population stability and growth due to improved spawning habitat and reproductive success in the Project Area, funded conservation projects for mussel species throughout the Grand River, benefits to other aquatic species, and the potential for permanent but small and spatially discrete increases in downstream mussel populations. Over 20% of Project benefits would accrue to agricultural areas as approximately 60% of the Grand River watershed from the Project Area downstream to Lake Michigan is agricultural land, and the proportion of agricultural lands in the upstream portion of the watershed is similar, if not higher (Hanshue, S. K., and A. H. Harrington, 2017).

Benefits Assessment:

Habitat changes from the Project are designed to benefit federal- and state-listed fish and mussel species, other fish and mussel species, and fish species that host mussel offspring. Added habitat boulders would create refuge areas and pockets of eddies and back eddies that add habitat diversity for a variety of fish species, including the listed lake sturgeon and river redhorse. The additional areas of habitat within the Project Area would contribute to increases in population size and/or stability of fish, and would likely contribute to increases in population size and/or stability of mussel species in areas downstream of the Project as well. The largest benefit to downstream populations would likely occur for both the lake sturgeon and river redhorse, as these species should experience the largest change in total spawning habitat available in the lower Grand River.

A mitigation fund will be created as mitigation for the loss of unionid mussel species during salvage would be used for threatened and endangered mussel species monitoring and other conservation measures, which would benefit mussel species in the lower Grand River, both upstream and downstream of the Project Area. The Fund would provide not only funds for future mussel monitoring projects, but it would also provide grant funding for future conservation measures, which could benefit mussel species outside of the Project Area. Additionally, indirect beneficial impacts would result from creating mussel habitat to the extent that the project's

Mitigation Fund is utilized for mussel habitat improvement projects either downstream or upstream of the Construction Area

Only 1% of river habitat in the lower peninsula of Michigan is composed of rapid-type habitat, which is important to the ecology and life cycle of many aquatic species. The existing site has been degraded by the low-head dams and has contributed to increased channelization of the river at this location. Enhancing rapid-type habitat through the Project would provide greater ecological diversity, which should benefit the greater watershed.

The Project is designed to increase Preferred Hydrophysical Habitat (PHH) for mussels by 78% over existing conditions. Therefore, more mussels should be able to inhabit the area than under existing conditions. If more mussels inhabited the Project Area, then more reproduction should occur in the Project Area, which would increase the chances of offspring being transported downstream and potentially inhabiting downstream locations. Comparatively, the increased benefits to mussel species populations likely would not be as great as to populations of fish species. Although the added PHH should increase mussel productivity, there likely is not enough adequate mussel habitat downstream of the Plaster Creek recipient site to significantly increase mussel abundance.

EA Modifications:

Revisions will be made to the following Plan-EA Sections:

- Summary – OMB Factsheet: Revision to watershed size and land use information to include entire Grand River Watershed, including agricultural information.
- Sections 4.6.1 and 4.6.2 – Affected Environment: Briefly describe fish and mussel species habitat and presence in the downstream portion of the Grand River.
- Section 6.6.2 – Environmental Consequences: Describe the aquatic ecological benefits described above.
- Appendix B – Figure 2: Watershed Land Use Map.

Cultural Resources Memorandum of Agreement 9/30/2022

NRCS Agreement N2622MOU0012399

MEMORANDUM OF AGREEMENT
AMONG
THE NATURAL RESOURCES CONSERVATION SERVICE,
THE MICHIGAN STATE HISTORIC PRESERVATION OFFICER,
THE MICHIGAN STRATEGIC FUND,
THE CITY OF GRAND RAPIDS, MICHIGAN,
GRAND RAPIDS WHITEWATER, INC.,
AND THE GRAND VALLEY METROPOLITAN COUNCIL

REGARDING

Removal of Four Beautification (Low-Head) Dams in the Grand River, Grand Rapids, Kent County, Michigan, a component of the Lower Grand River Watershed Habitat Restoration and Farmland Conservation Project

WHEREAS, the Natural Resources Conservation Service (NRCS) plans in cooperation with the Grand Valley Metropolitan Council (GVMC), the City of Grand Rapids (City) and Grand Rapids Whitewater, Inc. (GRWW) to carry out the Lower Grand River Watershed Habitat Restoration and Farmland Conservation Project (Project) located in the City of Grand Rapids, Michigan pursuant to the Watershed Protection and Flood Prevention Act of 1954, Public Law 83-566, as amended (WPFPA) (16 U.S.C. Sections 1001-1008, 1010, and 1012)through NRCS's Regional Conservation Partnership Program (RCPP) agreement number 1603 with GVMC; and

WHEREAS, the Project consists of (1) restoring aquatic habitat diversity and suitability for native Great Lakes drainage fish and mussel species, especially threatened, endangered, and special concern native species, in the Grand River; (2) reducing public safety hazards generated by the existing four beautification (low-head) dams (each, a "low-head dam", and, collectively as, the "low-head dams"); and (3) installing diversified hydraulic features that would improve aquatic habitat and aesthetics. Restoration of the site will require the demolition and removal of the low-head dams; and

WHEREAS, NRCS has determined that the removal of the low-head dams is an undertaking (Undertaking) subject to review under Section 106 of the National Historic Preservation Act (NHPA), as amended, 54 U.S.C. §306108 (Section 106), and its implementing regulations, 36 C.F.R. Part 800; and

WHEREAS, NRCS is the responsible federal agency with funding authority over the Undertaking pursuant to the WPFPA; and

WHEREAS, GVMC is the applicant for federal assistance through the RCPP and is responsible for ensuring the habitat restoration requirements of the RCPP agreement between the NRCS and the GVMC are met. GVMC will be signing this Memorandum of Agreement (MOA) as an invited signatory; and

WHEREAS, the City is the sponsoring local organization and permit applicant, and will be responsible for establishing contracts for demolition of the low-head dams and resulting habitat restoration and will be signing this MOA as an invited signatory; and

WHEREAS, GRWW is leading the design and engineering of the Project and will closely coordinate with the City and other partners to ensure the original intent of the design is accomplished and will be signing this MOA as an invited signatory; and

WHEREAS, the State Historic Preservation Officer is part of the State Historic Preservation Office (SHPO) which was transferred to the Michigan Strategic Fund (MSF) pursuant to Executive Order 2019-13; and

WHEREAS, NRCS has defined the Undertaking's Area of Potential Effects (APE) as the footprint of the low-head dam removal, an 840 m (2,756 feet) stretch of the Grand River flowing through the City from 40 m (130 ft) upstream of Bridge Street to Fulton Street and staging areas along the river; the low-head dams to be demolished are located between I-196 and Fulton Street and installation of substrate improvements within an area approximately 121,800 m^2 (30 acres) in size as further shown in the APE map attached hereto as Appendix A; and

WHEREAS, NRCS has determined, and the SHPO has concurred in their response letter regarding the Undertaking also referred to as SHPO Environmental Review 20-876, that the Undertaking will have an adverse effect on the low-head) dams in the Grand River due to their demolition and removal from the river. The low-head dams are eligible for listing on the National Register of Historic Places (NRHP) as documented in the NRHP Evaluation attached hereto as Appendix B, and NRCS has consulted with the SHPO and the Match-E-Be-Nash-She-Wish Band of Pottawatomi Indians Tribal Historic Preservation Officer (THPO) to develop this MOA pursuant to 36 Code of Federal Regulations Part 800 (36 C.F.R. Part 800), the regulations implementing Section 106 of the National Historic Preservation Act (54 U.S.C. § 306108); and

WHEREAS, the low-head dams are eligible for listing on the NRHP under the following eligibility criteria: Criterion A as a series of structures that conveys the long history of the City with the Grand River and for their role in the emergence of city planning and the development of the riverfront as a focal point of downtown Grand Rapids and Criterion C, given that the low-head dams are works of architecture and engineering and embody the distinctive characteristics of a type, period or method of construction. The mitigation measures documented in the stipulations below must address the criteria that qualify the low-head dams for listing on the NRHP; and

WHEREAS, NRCS has reached out to the 12 Federally Recognized Tribes, and the two State Historic Tribes within Michigan as well as the Miami Tribe of Oklahoma with information and updates regarding the planned Undertaking. The Little River Band of Ottawa Indians, the Miami Tribe of Oklahoma, the Pokagon Band of Potawatomi, and the Saginaw Chippewa Indian Tribe of Michigan, responded to NRCS consultations and indicated that they should be contacted in the event a post review discovery is made; and

WHEREAS, the Match-E-Be-Nash-She-Wish Band of Pottawatomi Indians, [redacted] responded to NRCS consultations with interest and NRCS pursued consultation through the THPO**;** and

WHEREAS, NRCS has consulted with the Grand Rapids Public Museum (GRPM) regarding the effects of the Undertaking on historic properties and has invited GRPM to sign. GRPM will be signing this MOA as a concurring party; and

WHEREAS, in accordance with 36 C.F.R. § 800.6(a)(1), NRCS has notified the Advisory Council on Historic Preservation (ACHP) of its adverse effect determination with specified

documentation, and the ACHP has chosen not to participate in the consultation pursuant to 36 C.F.R. § 800.6(a)(1)(iii); and

WHEREAS, NRCS has provided the public the opportunity to comment on the Undertaking and proposed mitigation measures by issuing a public notice through local media, on the NRCS Michigan website, partner websites and posting at local public libraries. Two public meetings were held virtually on November 10th and 29th, 2021, to provide information on the original purpose and present mitigation measures to address the removal of the low-head dams. Over the course of 30 days, 47 public comments were received and provided to the SHPO. Seven comments specifically addressed the removal of the low-head dams. These seven were reviewed and considered in development of this MOA. Remaining comments addressed other issues not related to the low-head dams; and

WHEREAS, an architectural historian will be present to monitor and document the low-head dam removal since the historic structures eligible for listing on the NRHP are extant engineered structures. An archaeologist will not be onsite during low-head dam removal for monitoring below ground disturbance because the riverbed was significantly disturbed when the low-head dams were installed and planned ground disturbance for the Undertaking will be limited. Dredging or scraping of the river for demolition of the dams will not exceed the previous level of disturbance associated with construction of the dams. Ah-Nab-Awen Park, a staging area, has three to five feet of fill. An archaeologist will be available to respond in the event a post review discovery is made during construction in accordance with the Inadvertent Discovery Plan for Cultural Resources or Human Remains attached hereto as Appendix E (Inadvertent Discovery Plan); and

WHEREAS, the term "Signatory" is defined in this MOA to include both Signatories and Invited Signatories; and

WHEREAS, nothing in this MOA shall be construed as requiring a Signatory or Concurring Party to expend funds in violation of the Anti-deficiency Act, codified at 31 U.S.C. § 1341, as amended; and

WHEREAS, terms and parties not otherwise defined in this MOA shall have the meaning assigned to them in the Glossary of Terms attached hereto as Appendix G.

NOW, THEREFORE, NRCS, SHPO, MSF, the City, GRWW, and GVMC agree that the Undertaking shall be implemented in accordance with the following stipulations in order to take into account the effect of the Undertaking on historic properties.

STIPULATIONS

NRCS shall ensure that the following measures are carried out:

I. MONITORING OF LOW-HEAD DAM REMOVAL BY ARCHITECTURAL HISTORIAN

The City and GRWW will provide a qualified architectural historian to conduct monitoring of the removal of one of the low-head dams within the coffered de-watered area to document the resource as it exists in accordance with SHPO's Documentation Standards attached hereto as Appendix C (Documentation Standards). As the plans show that the low-head dams are identical in design and construction, observation of one removal is expected to provide sufficient information on construction of the low-head dams. Note that if the field conditions at the time of removal of the

first coffered low-head dam do not facilitate the desired observations, NRCS may request that the removal of the second low-head dam within a coffered area, also be monitored as described below. The architectural historian will be monitoring demolition of a low-head dam since the historic property being removed is an extant engineered structure. An archaeologist will not be onsite during monitoring because ground disturbance will be limited. Dredging or scraping for demolition of the dams will not exceed the previous level of disturbance associated with construction of the dams. Ah-Nab-Awen Park, a staging area, has three to five feet of fill. An archaeologist will be available to respond in the event a post review discovery is made during construction in accordance with the Inadvertent Discovery Plan. The monitoring will:

A. Focus on identifying and documenting the form and content of the low-head dam with sketch drawings and high-resolution photographs

B. Focus on how the low-head dam was constructed and any evidence of maintenance or modifications post-construction

C. Allow the City's architectural historian to attempt to recover any significant architectural elements identified within the coffered area as feasible and safe within the constraints of low-head dam removal site activities and schedule

D. Include application of the Inadvertent Discovery Plan as needed during all Project activities. During monitoring of removal of the low-head dams, the architectural historian on site will implement the Inadvertent Discovery Plan if needed and NRCS shall engage archaeological and tribal representative assistance as appropriate.

E. Allow the City's architectural historian to coordinate with NRCS to arrange for curation and display if significant architectural elements and/or archaeological remains are recovered.

The final report from the City's architectural historian shall follow the Documentation Standards and will be submitted to NRCS within 90 days of completion of the monitoring work. NRCS will then submit the final report to the SHPO for deposit in the State Archives of Michigan, and with the City's Community Archives and Research Center. The historic documentation developed from monitoring shall adhere to the Secretary of the Interior's Standards and Guidelines for Archaeology and Historic Preservation (48 Fed. Reg. 44716 (Sept. 29, 1983)).

II. PRESENTATION OF INTERPRETIVE MATERIALS

The following actions will be completed within one year of completion of low-head dam demolition.

A. Interpretive Panel(s)

i. The City and GRWW, in consultation with NRCS, will provide interpretative panel(s) to be placed along the river walkway in Ah-Nab-Awen Park or on the GRPM grounds (Panel(s)).

ii. The Panel(s) will be constructed on a durable outdoor product with UV resistant, graffiti resistant, and burn resistant material. Examples can be found at: http://www.pulsedesign.com/outdoor-interpretive-signs-historic-preservation-site-educational-exhibits

iii. The City and GRWW in consultation with NRCS and the other consulting parties will develop an interpretive design to describe the content of the Panel(s).

iv. Content, including text and images, for the Panel(s) will be reviewed by NRCS, in consultation with the SHPO, to ensure the content meets the Secretary of the Interior's Professional Qualifications Standards. NRCS will provide a draft image of all Panel(s)

to the signatories for comment for a period of 30 days. NRCS will consider all timely comments in developing final designs and text for the Panel(s).

v. The City and GRWW will install the Panel(s) during site restoration of Ah-Nab-Awen Park. The City shall ensure maintenance of the Panel(s). A digital copy of the Panel(s) will also be provided to the SHPO and the City for archiving.

B. River Restoration Photo Monitoring Project

i. GVMC is collecting photos of the current conditions and future low-head dam removal locations in the River Restoration Photo Monitoring Project. (https://www.lgrow.org/river-restoration)

ii. GVMC will create a timelapse video from these photos to document the entire low-head dam removal and watershed restoration process and make the video available to the public. The final product will be archived with the State Archives of Michigan and the City.

C. Museum Collections, Exhibits

The City will coordinate with a local historical institution to assure they have access to any appropriate documentation of the Project and removal of the low-head dams that they would like to incorporate into their educational programming, collections, or exhibits. Educational materials and exhibits shall comply with Federal Curation Regulations found at 36 C.F.R. § 79 as attached hereto as Appendix D (Federal Curation Regulations).

III. QUALIFICATIONS STANDARDS

NRCS shall ensure that all work carried out pursuant to this MOA shall be done by or under the direct supervision of historic preservation professionals who meet the Secretary of the Interior's Professional Qualifications Standards found at 36 C.F.R. § 61 (SOI Standards). NRCS shall ensure that all consultants retained for services pursuant to the MOA Agreement meet the SOI Standards.

The Section 106 regulations (36 CFR § 800.4(c)(1)) acknowledge that Indian tribes and Native Hawaiian organizations (NHOs) possess "special expertise" in assessing the eligibility of historic properties that possess religious and cultural significance to them. Individuals recognized by a tribe or NHO as possessing this special expertise do not have to meet the SOI Standards for purposes of Section 106 review.

IV. CURATION STANDARDS

Any artifacts collected and accessioned will be curated according to the Federal Curation Regulations.

V. PROJECT MODIFICATIONS AND CHANGES

Neither the NRCS, GVMC, the City nor GRWW shall alter any plan, scope of services, or other document that has been reviewed and commented on pursuant to this MOA (except to finalize documents commented on in draft form), without first affording the signatories to this MOA the opportunity to review the proposed change and determine whether it shall require that this MOA be amended. If one or more such signatory determines than an amendment is needed, the signatories to this MOA shall consult in accordance with Stipulation XIV to consider such an amendment.

VI. COMPLIANCE WITH OTHER FEDERAL, STATE, TRIBAL AND LOCAL LAWS

A. NRCS shall coordinate its compliance with Section 106 with other applicable federal, state/tribal, and local laws and reviews as appropriate.

B. Historic and prehistoric human remains from non-federal, non-tribal lands are subject to protection under Michigan burial/unmarked grave/cemetery law(s), the Michigan Attorney General's Opinion No. 6585 and Michigan Penal Code, Act 328 of 1931 Chapter XXVI, Section 750.160. As such, if human remains are discovered during removal of the low-head dams and watershed restoration, work in that portion of the Project shall stop immediately. The remains shall be covered and/or protected in place in such a way that minimizes further exposure of and damage to the remains, and NRCS shall immediately consult with the SHPO and THPO. If the remains are found to be Native American, in accordance with applicable law, a treatment plan shall be developed by NRCS and SHPO in consultation with appropriate federally recognized Indian tribes. NRCS shall ensure that any treatment and reburial plan is fully implemented. If the remains are not Native American, the appropriate local authority shall be consulted to determine final disposition of the remains. Avoidance and preservation in place is the preferred option for treating human remains.

VII. POST-REVIEW DISCOVERIES

If properties are discovered that may be historically significant or unanticipated effects on historic properties found, once notified of the discovery, NRCS shall continue to implement the Inadvertent Discovery Plan.

VIII. COMMUNICATION AMONG MOA PARTIES

Electronic mail (email) will serve as the official correspondence method for all communications regarding this MOA and its provisions. A list of all Signatory contacts and email addresses is attached hereto as Appendix F (Contact Information). Contact Information may be updated without an amendment to this MOA. It is the responsibility of each Signatory or Concurring Party to immediately inform NRCS of any change in name, address, email address, or phone number of any point-of-contact. NRCS shall forward updated Contact Information to all Signatories and Concurring Parties by email.

IX. ANTIDEFICIENCY ACT

NRCS's obligations under this MOA are subject to the availability of appropriated funds, and the stipulations of this MOA are subject to the provisions of the Anti-deficiency Act. NRCS shall make reasonable and good faith efforts to secure the necessary funds to implement this MOA in its entirety. If compliance with the Anti-deficiency Act alters or impairs NRCS's ability to implement the stipulations of this MOA, NRCS shall consult in accordance with the amendment and termination procedures found at Stipulations XIV and XV of this MOA.

X. EMERGENCY SITUATIONS

Should an emergency situation occur which represents an imminent threat to public health or safety, or creates a hazardous condition, NRCS shall immediately notify the SHPO, THPO and the ACHP of the condition which has initiated the situation and the measures taken to respond to the emergency or hazardous condition. Should the SHPO, THPO or the ACHP desire to provide technical assistance to NRCS, they shall submit comments within seven (7) calendar days from receipt of the notification, if the nature of the emergency or hazardous condition allows for such coordination.

XI. DURATION

This MOA will expire if its terms are not fully carried out within five (5) years from its execution. Prior to such time, NRCS may consult with the other Signatories to reconsider the terms of this MOA and amend it in accordance with Stipulation XIV below.

XII. AGREEMENT MONITORING AND REPORTING

A. On each anniversary following the execution of this MOA, until it expires or is terminated,

NRCS shall provide all Signatories and Concurring Parties to this MOA a summary report detailing work undertaken pursuant to its terms. Such report shall include any scheduling changes proposed, any problems encountered, and any disputes and objectionsreceived in NRCS's efforts to carry out the terms of this MOA.

B. The City, GRWW, and GVMC shall submit quarterly summary reports (Quarterly Reports) to NRCS detailing (1) any scheduling changes proposed, (2) any problems encountered, (3) any disputes and objections received and (4) all efforts to carry out the responsibilities and terms of this MOA.

C. NRCS shall create annual reports based on the Quarterly Reports and distribute to all Signatories and Concurring Parties.

XIII. DISPUTE RESOLUTION

Should any Signatory or Concurring Party to this MOA object (Objection) at any time to any actions proposed or the manner in which the terms of this MOA are being implemented, NRCS shall consult with such Signatory or Concurring Party to resolve the Objection. If NRCS determines that such Objection cannot be resolved, NRCS will:

A. Forward all documentation relevant to the Objection, including the NRCS's proposed resolution, to the ACHP. The ACHP shall provide NRCS with its advice on the resolution of the Objection (Advice) within thirty (30) days of receiving adequate documentation (Advice Period).

1. If the ACHP provides its Advice within the Advice Period, NRCS shall prepare a written response (Response) prior to reaching a final decision on the Objection (Final Decision) that takes into account any timely advice or comments regarding the Objection from the ACHP, Signatories and Concurring Parties, and provide them with a copy of the Response. NRCS will then proceed according to its Final Decision.

2. If the ACHP does not provide its Advice within the Advice Period, NRCS may make its Final Decision and proceed accordingly. Prior to reaching the Final Decision, NRCS shall prepare a Response that takes into account any timely comments regarding the Objection from the Signatories and Concurring Parties, and provide them and the ACHP with a copy of the Response.

B. NRCS's responsibility to carry out all other actions pursuant to the terms of this MOA that are not the subject of the Objection remain unchanged.

XIV. AMENDMENTS

This MOA may be amended when such an amendment is agreed to in writing by all Signatories. The amendment will be effective on the date a copy signed by all the Signatories is filed with the ACHP.

XV. TERMINATION

If any Signatory to this MOA determines that its terms will not or cannot be carried out (Objecting Signatory), the Objecting Signatory shall immediately consult with the other Signatories to attempt to develop an amendment pursuant to Stipulation XIV, above. If, within thirty (30) days (or another time period agreed to by all Signatories), an amendment cannot be reached, any Signatory may terminate the MOA upon written notification to the other Signatories.

Once the MOA is terminated, and prior to work continuing on the Undertaking, NRCS must

either (a) execute a new MOA pursuant to 36 CFR § 800.6 or (b) request, take into account, and respond to the comments of the ACHP under 36 CFR § 800.7. NRCS shall notify the Signatories as to the course of action it will pursue.

XVI. USDA STIPULATIONS

A. The Signatories and their respective agencies will handle their own activities and utilize their own resources, including the expenditure of their own funds, in pursuing these objectives. Each signatory will carry out its separate activities in a coordinated and mutually beneficial manner.

B. Nothing in this MOA shall obligate either the Department of Agriculture or any of the Signatories to obligate or transfer any funds Specific work projects or activities that involve the transfer of funds, services or property among the Signatories and their respective agencies will require execution of separate agreements and be contingent upon the availability of appropriated funds. Such activities must be independently authorized by appropriate statutory authority. This MOA does not provide such authority. Negotiation, execution and administration of each such agreement must comply with all applicable statutes and regulations.

C. This MOA is not intended to, and does not create, any right, benefit, or trust responsibility, substantive or procedural, enforceable at law or equity, by a party to this MOA against the United States, its agencies, its officers, or any person.

Execution of this MOA by the NRCS, SHPO and MSF and implementation of its terms is evidence that NRCS has taken into account the effects of this Undertaking on historic properties and afforded the ACHP an opportunity to comment.

ABSTRACT

The Michigan State Historic Preservation Office (MI SHPO) has requested a National Register of Historic Places (NRHP) evaluation of the eligibility of four low-head dams in the Grand River in Grand Rapids, Michigan that would be affected by the Grand Rapids Whitewater Project (Project), which proposes the removal of these dams. With the support of the City of Grand Rapids and Grand Rapids Whitewater (GRWW), Environmental Resources Management (ERM) prepared this report evaluating whether the beautification dams constructed along the Grand River in the early twentieth century are eligible for the NRHP, and if so, whether the Project may result in adverse effects to these cultural resources. The U.S. Department of Agriculture's Natural Resources Conservation Service (NRCS) is the lead federal agency with funding authority over the undertaking.

The Project spans approximately 0.7 miles along the downtown portion of the Grand River, and includes the removal of four low-head, historic-aged dams associated with the early industrial and commercial growth of Grand Rapids, as well as other changes in the river. Another dam in the Grand River upstream of the Project, the Sixth Street Dam and Fish Passage, has already been recommended eligible for the NRHP, and has been addressed as a separate undertaking. This report evaluates the four dams located from just north of Bridge Street to just north of Pearl Street. In order to evaluate the significance of the dams, ERM collected information on the dams and their context within the history of Grand Rapids from experts knowledgeable in local history, city planning, and historical public works. Documents, maps, and photographs were collected from the Grand Rapids City Archive and Record Center, the Grand Rapids Public Museum, the Grand Rapids Public Library, and the Grand Rapids Historical Commission.

Based on the information gathered, ERM recommends that the four low-head dams, referred to as the Beautification Dams in Grand River, are potentially eligible for the NRHP. The dams meet the requirements for listing under Criterion A for their role in the emergence of city planning and the development of the riverfront as a focal point of downtown development in Grand Rapids, and under Criterion B for their association with city planner Harland Bartholomew, whose ideas on city beautification influenced the development of Grand Rapids during the twentieth century. ERM also recommends that the Project would have an adverse effect on the properties. The Project plan as currently proposed requires removal of all the dams and does not allow for avoidance or minimization of adverse effects. ERM recommends that, should MI SHPO concur with this assessment, a plan be developed to mitigate the adverse effects of the Project on the four low-head dams.

1. INTRODUCTION

1.1 Overview

Michigan State Historic Preservation Office (MI SHPO), in the course of consultation regarding the Project, has requested an evaluation of National Register of Historic Places (NRHP) eligibility of four low-head dams in the Grand River in Grand Rapids that would be affected by the Project, which proposes the removal of these dams in an effort to restore the river to a more natural state. With the support City of Grand Rapids and Grand Rapids Whitewater (GRWW), Environmental Resources Management (ERM) prepared this report evaluating whether the beautification dams constructed along the Grand River in the early twentieth century are potentially eligible for the NRHP, and if so, whether the Project may result in adverse effects to these cultural resources.

The Project requires funding authorization from the NRCS, and must comply with the provisions of the National Environmental Policy Act (NEPA) of 1970 and the National Historic Preservation Act (NHPA) of 1966. The need for federal authorization requires Project review under Section 106 of the NHPA, as amended. Section 106 of the NHPA (54 United States Code § 306108) requires federal agencies, including NRCS, to take into account the effects of their undertakings on historic properties and to afford the Advisory Council on Historic Preservation (ACHP) an opportunity to comment. Historic properties are defined as cultural resources that are listed or eligible for listing in the NRHP (36 Code of Federal Regulations [CFR] 60). GRWW, as a non-federal party, is assisting the Natural Resources Conservation Service (NRCS) in meeting its obligations under Section 106 by preparing the necessary information, analyses, and recommendations as authorized by 36 CFR § 800.2(a)(3).

On December 20, 2018, ERM, on behalf of NRCS, submitted a request for initial consultation regarding the Lower Grand River Watershed Habitat Restoration Project. On June 18, 2020, NRCS submitted an update to that submittal. MI SHPO responded on June 29, 2020 with a request for more information regarding the four low-head dams to be removed as part of the river restoration. Additional information was provided on November 2, 2020, to which MI SHPO responded with a request for further information regarding the known history and current condition of the four low-head dams (December 17, 2020, ER20-876). MI SHPO requested that additional information be provided about the dams to be removed by the Project, along with historical context that would help frame their potential eligibility for the NRHP. The current report was prepared to satisfy that request.

The Project includes the following:

- The Construction Area—the area within the wetted channel of the Grand River from approximately 130 feet upstream of the Bridge Street Bridge to the upstream edge of the Fulton Street Bridge
- The Project Area—the areas where Project activities would occur:
  - Portions of the land on both sides of the Grand River from the 6th Street Dam to Fulton Street (where construction access or staging areas would occur)
  - The wetted channel of the river from 130 feet upstream of the Bridge Street Bridge to the upstream face of the Fulton Street Bridge (the Construction Area)
  - Three recipient sites in the river for the placement of relocated unionid mussels. The three recipient sites are mussel beds near Ada, Michigan; at Riverside Park just upstream of Grand Rapids; and between Plaster Creek and the M-11 (28th Street) Bridge.

The Project's Area of Potential Effect (APE) is defined for direct effects as the Construction Area and Project Area, and for indirect effects as areas immediately adjacent to the Construction Area. Direct effects on the four low-head dams scheduled for removal are the subject of this report. Proposed earth

disturbance is not planned beyond the confines of the active river channel except for construction access points and temporary staging areas on the banks.

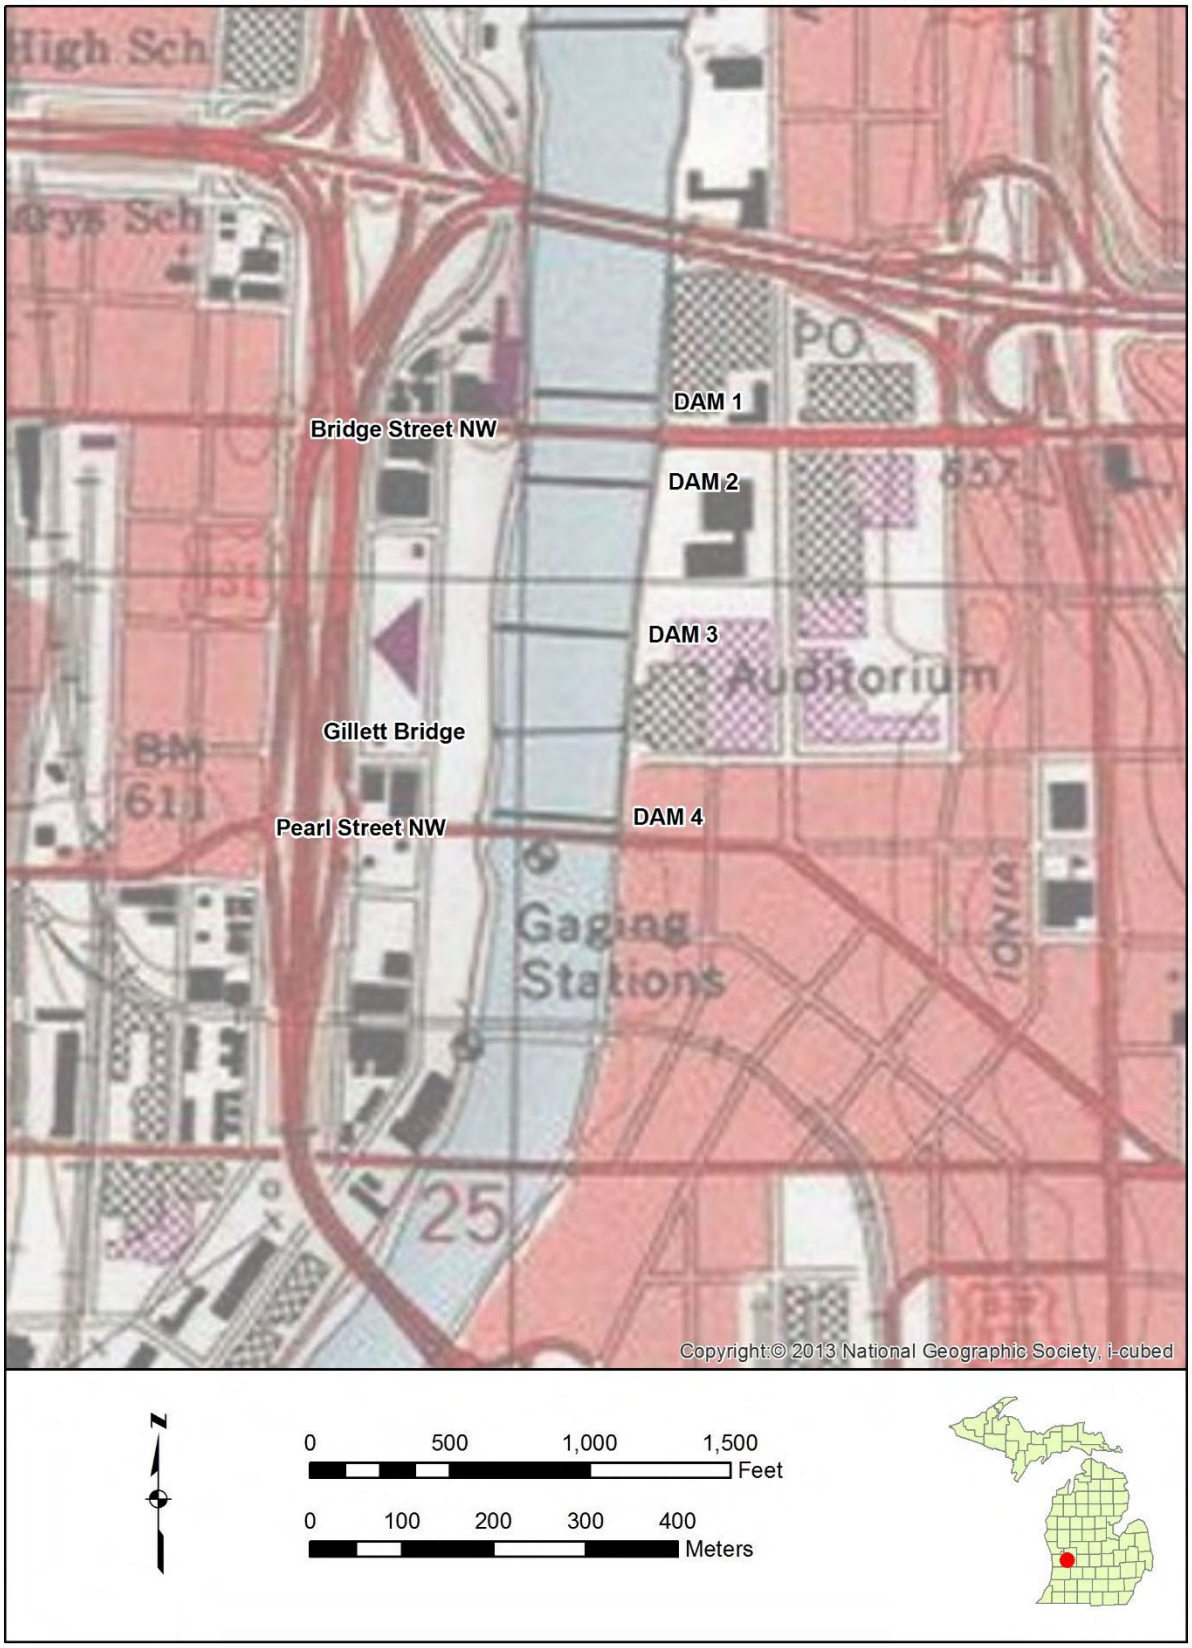

Figure 1.1-1: Topographic Map Showing Location of Dams

Figure 1.1-2: Current Aerial Imagery of Beautification Dams

The Project spans approximately 0.7 miles along the downtown portion of the Grand River, and includes the removal of four low-head, historic-aged dams associated with the twentieth century commercial growth of Grand Rapids, as well as other changes in and near the river (Figures 1.1-1 and 1.1-2). Another dam in the river at Grand Rapids, the Sixth Street Dam and Fish Passage, was constructed earlier than the other four, and was originally intended for water power. It was repaired and improved in 1926 as part of the planned improvements to the river recommended by city planner Harland Bartholomew. This dam has already been determined eligible for the NRHP (Robinson et al. 2020; B. Grennell to C. Sedlacek, letter dated 6 October, 2020). The current report evaluates the four dams located from just north of Bridge Street to just north of Pearl Street. In order to evaluate the significance of the dams, ERM collected information on the dams and their context from online sources and experts knowledgeable in local history, city planning, and historical public works. Documents, maps, and photographs were collected from the Grand Rapids City Archive and Record Center (GRCARC), the Grand Rapids Public Museum (GRPM), the Grand Rapids Public Library (GRPL), and the Grand Rapids Historical Commission (GRHC).

The four dams were constructed in 1927 as part of a plan to beautify the river through downtown. The creation of canals on both sides of the river for power and industrial use had led to low water levels in the river during dry periods, creating fetid pools and the growth of brush in the channel. The construction of low-head dams to create run-of-the-river pools had been recommended by Harlan Bartholomew as part of the 1925 City Plan (Bartholomew 1925). The proposed undertaking would entail removal of all four dams to reinstitute rapids in the riverbed, improving aquatic habitat diversity, improving public health and safety, expanding use of the river, and improving recreational use of the river. This report will evaluate the potential NRHP eligibility of the four Beautification Dams proposed for removal as part of the Project.

1.2 Management Recommendations

Based on the information gathered, ERM recommends that the four low-head dams, referred to as the Beautification Dams in Grand River, are eligible for the NRHP. The dams meet the requirements for listing under Criterion A for their role in the emergence of city planning and the development of the riverfront as a focal point of downtown development in Grand Rapids, and under Criterion B for their association with city planner Harland Bartholomew, whose ideas on city beautification influenced the development of Grand Rapids during the twentieth century. ERM also recommends that the Project would have an adverse effect on the properties. The Project as currently proposed requires removal of all the dams and does not allow for avoidance or minimization of adverse effects. ERM recommends that, should MI SHPO concur with this assessment, a plan be developed to mitigate the adverse effects of the Project

2. HISTORIC CONTEXT

When settlers began to congregate around the Baptist Mission on the west bank of the Grand River and the trading post established by Louis Campau on the east side of the river at what is now Grand Rapids in the 1820s, the river was described as a mile-long cascade of rapids that was 300 yards wide and dropped a total of 10 to 15 feet. A map made in 1830 (Grand Rapids Public Library 1830) shows the rapids that spanned the length of the city's street grid (Figure 2.0-1). The potential water power that the river could provide was immediately recognized, and by at least 1833, the river was being used for power. In 1835, the first dam was constructed on the river. The stone wing dam was located near Eleventh Street to the north of the Project area, and diverted water into the East Side Power Canal to provide waterpower to a sawmill and gristmill. The canal was extended for a mile along the river and was completed in 1842, providing power to a number of industries until it was abandoned in 1925. In 1849, a log and stone dam was constructed across the width of the river in an attempt to expand the canal for navigation. The canal project was a failure, but the horseshoe-shaped dam near Sixth Street remained until after 1878 (Figure 2.0-2) (Biolchini 2019; Robinson, et al. 2020).

Figure 2.0-1: Map of Grand Rapids in 1830 Showing the Rapids through the City (North is to the right) (GRPL)

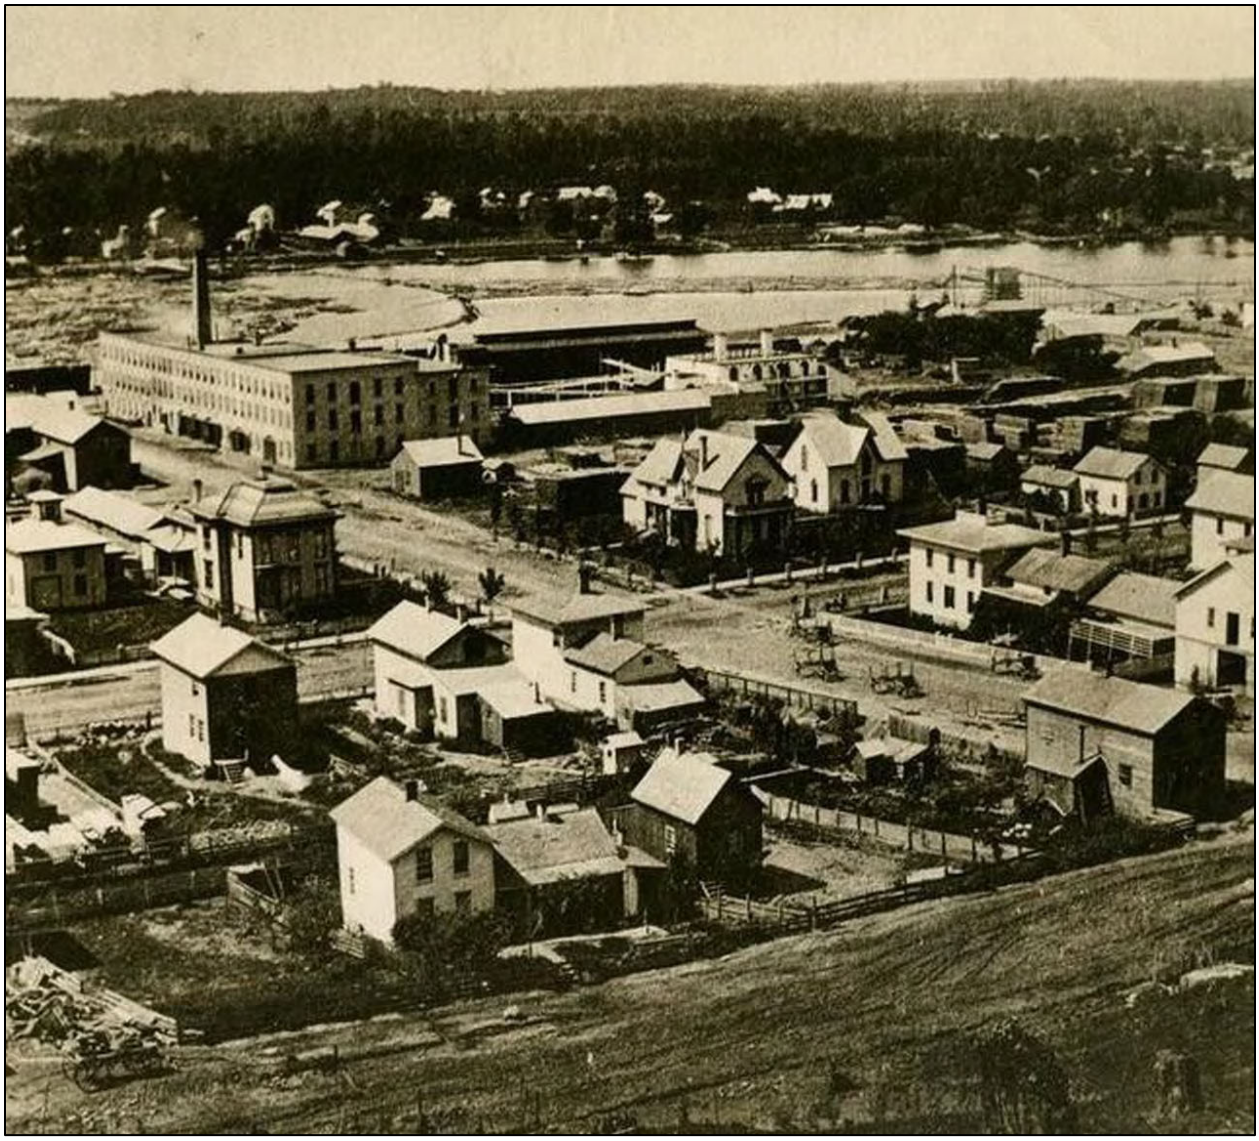

Figure 2.0-2: View of Grand Rapids in 1865 with the 1849 Horseshoe Dam in the Background (GRPL)

In 1866, the West Side Water Power Association began construction on the West Side Canal. Through an agreement with the East Side Water Power Company, the water rights would be split between the two companies, and a new, more permanent timber crib dam would be constructed across the river at Fourth Street that would serve both canals. This was known as the water power dam, or Fourth Street Dam (Figure 2.0-3). It was located a few blocks south of the earlier horseshoe dam, which remained in place until at least 1878 but was gone by 1888 (GRCARC 1873, 2019; Sanborn Map Company 1888). The Fourth Street Dam was later known as the Sixth Street Dam (Robinson et al. 2020).

In the early twentieth century, Grand Rapids experienced a series of disastrous floods. The first of these in 1904 damaged a 150-foot section of the Fourth Street Dam. At that time, it was suggested that a concrete dam replace the 1866 timber crib dam, although it appears that the dam was simply repaired (*Grand Rapids Herald* 1904). The city hired Lyman E. Cooley, an engineer from Chicago, to make recommendations regarding flood control and improving water power. Cooley proposed in 1904 that flood

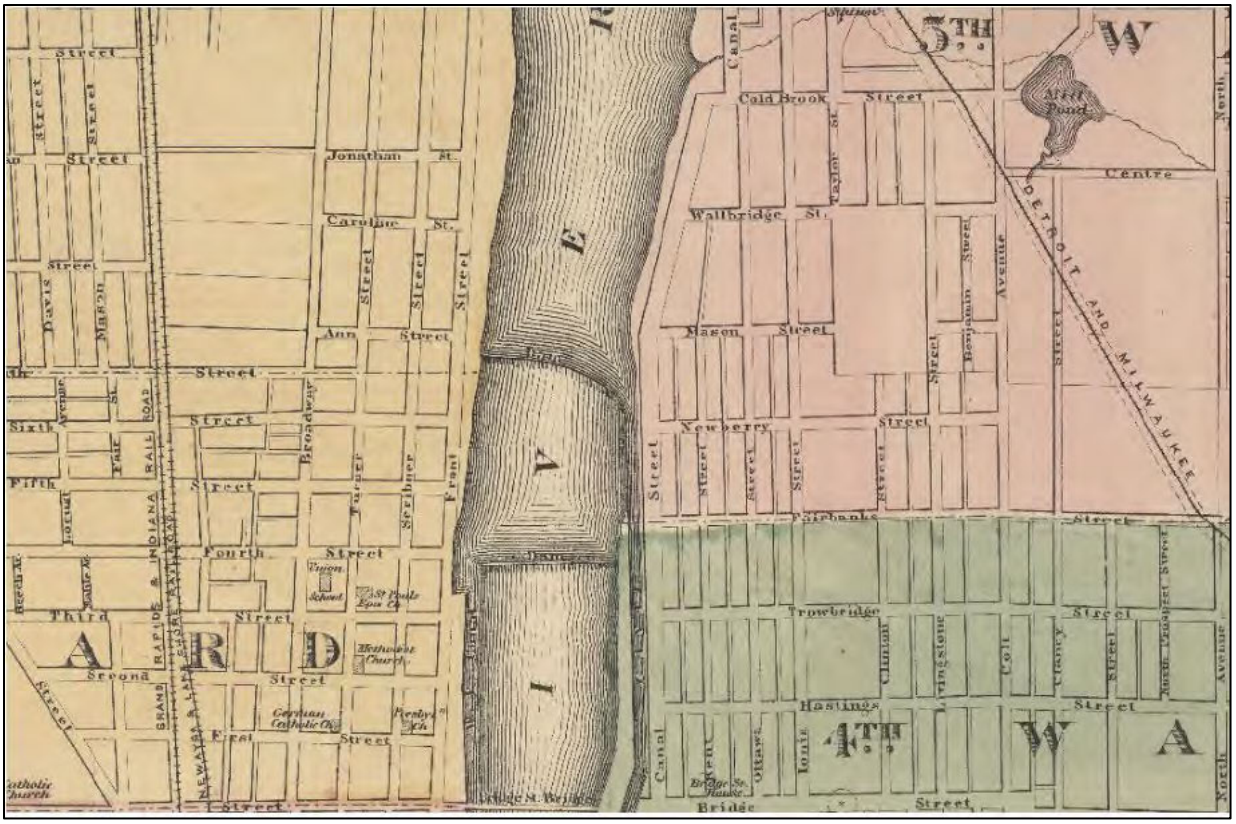

Figure 2.0-3: Map of Grand Rapids in 1873 Showing the 1866 Fourth Street Dam, the 1849 Horseshoe Dam, and the East and West Side Canals (GRCARC)

walls be constructed through the city, and work on these was begun soon after (Figure 2.0-4; Lydens 1966:122). In 1909, Cooley proposed that a new dam be constructed 300 feet north of Bridge Street. This dam was apparently not constructed (Biolchini 2019; Cooley 1909; Forist and Gleisner 2015).

In 1915, another major flood took out a 100-foot section of the western part of the Fourth Street Dam. Plans were proposed for the repair of the dam, with both a timber crib replacement and an upgrade to concrete being considered. The design of the concrete section is nearly identical to the plans later used for the Beautification Dams downstream. It appears from later plans that the damaged section was replaced with concrete, and the remaining timber crib section was replaced in 1926 when the beautification project was undertaken (GRCARC 2019).

The idea of a series of low-head dams on the Grand River in order to maintain water in the river bed and prevent the accumulation of trash and brush in the river was proposed by city planner Harland Bartholomew, whose firm was hired by the Grand Rapids Planning Department in the early 1920s to develop a master plan for the city (GRPL 2017). The diversion of water for the East and West Side Canals and city water works had resulted in the river often lacking a constant flow, resulting in the accumulation of trash and brush in the riverbed (Figure 2.0-5). The low-head dams would maintain the flow of the river and would “add greatly to the appearance and provide ample water surface for boating,” according to Bartholomew (Bartholomew 1925; Biolchini 2019; GRPM ca. 1926). An appropriation was approved for the beautification project in March 1926, but it was not until May 1927 that a bid of $24,112 was accepted from a Grand Rapids firm for the construction, with an expected completion date of

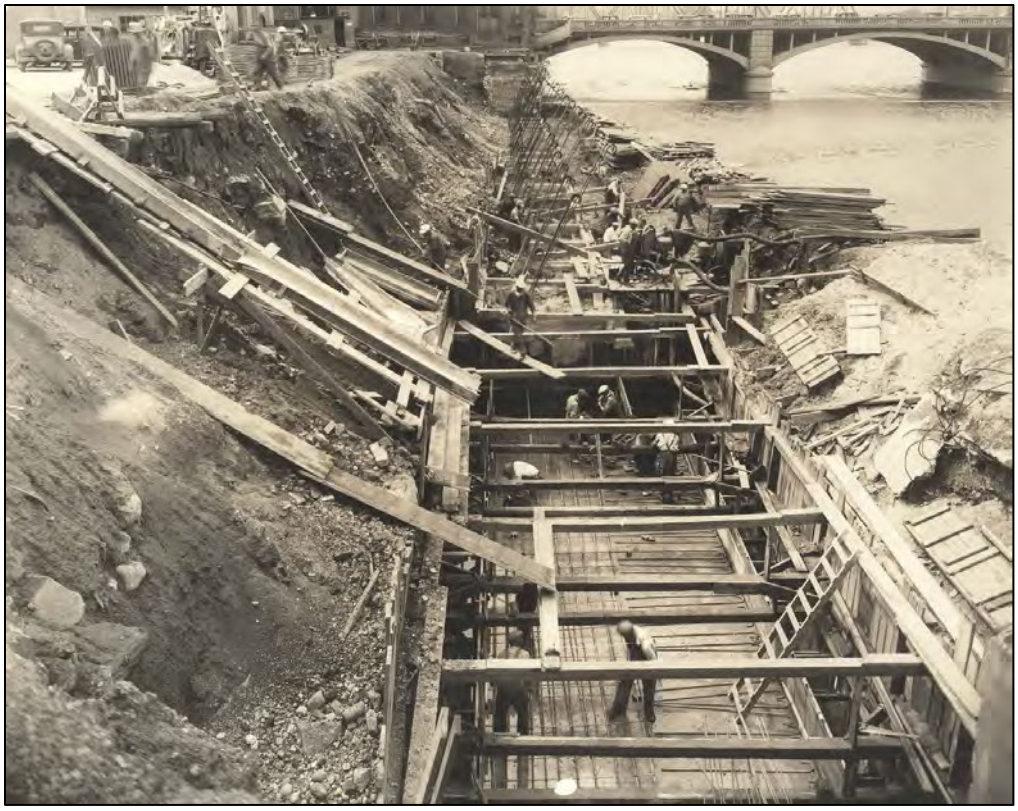

Figure 2.0-4: Construction of Flood Walls on the East Side of the River above the Pearl Street Bridge (GRCARC)

Figure 2.0-5: View of Downtown and the River Showing Brush Growing in the Riverbed Downstream of the Fourth Street Dam (GRPM)

January 1, 1928. The *Grand Rapids Press* praised the city for approving the plan, which would help the river "take on some of the beauty which existed before drought and the west side canal removed all liquid attractions" (*Grand Rapids Press* 1927a, 1927b).

The dams were constructed by diverting water using a coffer dam, leaving the riverbed dry (Figure 2.0-6) (*Grand Rapids Herald* 1927). They were completed by January 2, 1928, when a report of the Engineers' Office noted that it had overseen the placement of the dams at a cost of $37,000. In April 1928, the mayor remarked that the dams had "improved the appearance of the river 100 percent." In July 1928, the *Grand Rapids Press* remarked, "By expenditure on a series of carefully placed dams Grand Rapids has succeeded, without increasing its flood hazard in restoring some of the beauty of Grand river between the main dam at Fourth street and a point two or three hundred feet north of Pearl Street bridge" (*Grand Rapids Press* 1928a, 1928b).

The dams have remained in place to the present, with no known significant changes. The purposes of the dam construction project were well realized, as the water level was maintained, and public and private development became more focused on the river in the twentieth century. Numerous parks and public and private attractions have been established on both sides of the river, including the Gerald R. Ford Presidential Museum, Grand Rapids Public Museum, the Civic Auditorium (now part of the DeVos Place Convention Center), Ah-Nab-Awen Park, and Sixth Street Park.

Details related to the conception, design and construction of the Beautification Dams, as well as their place within the context of city planning in general and the work of Harland Bartholomew in particular, are discussed in greater detail in Section 4.

Figure 2.0-6: Dry Bed of the Grand River during Construction of Beautification Dams, View to the South from Bridge Street Bridge; Dam #2 is in the Foreground (GRCARC)

3. METHODS

3.1 Survey Methods

The current investigation was prompted by a request from the MI SHPO for additional information about the four low-head dams and their historical context to assist in a determination of eligibility. In a comment letter dated December 17, 2020, MI SHPO requested survey information about the nature and condition of the dams and a discussion of their potential NRHP eligibility within a proper historical context.

Because of accessibility issues due to the COVID-19 pandemic and the fact that the dams are currently covered by water, ERM architectural historians undertook a remote survey of the properties based on historical plans and historical and current photographs from a variety of sources including the GRCARC, GRWW, GRPL, Google Earth, and previous site visits. The photographs were used to record the structures' overall appearance and details. Topographic maps and aerial photographs were used to record the relationship of the structures to each other and the surrounding landscape features and infrastructure.

A Michigan State Architectural Properties Identification Form was completed as part of the recordation process, which is attached in Appendix A.

3.2 Documentary Research

In order to assess the significance of the dams, ERM collected information from knowledgeable experts in local history, city planning, and historical public works. ERM conducted online research to identify historic themes, events, and patterns important in the development of local, regional, and national significance. Local government records and information provided by knowledgeable local organizations also were examined to establish a context for the development of the water control systems in Grand Rapids, as well as specific details relating to the system as built and as it exists today. Documents, maps, and photographs were collected from the GRCARC, the GRPM, the GRPL, and the GRHC.

3.3 NRHP and Effects Evaluation

The four dams were evaluated with respect to their eligibility for listing on the NRHP using published guidance from the National Park Service. According to 36 CFR 60.4 (Andrus and Shrimpton 2002), cultural resources eligible for listing on the NRHP are defined as buildings, structures, objects, sites, and districts that have "integrity" and that meet one or more of the criteria outlined below. Criterion D is typically relevant to archaeological sites. Historic resources are generally evaluated in relation to Criteria A, B, and C. Criterion C is typically applicable to architectural resources but also may be relevant in the case of resources that are associated with landscape architecture (like cemeteries or battlefields) or engineering (like dams, bridges, railroads, and mines).

- Criterion A (Event). Association with one or more events that have made a significant contribution to the broad patterns of national, state, or local history
- Criterion B (Person). Association with the lives of persons significant in the past
- Criterion C (Design/Construction). Embodiment of distinctive characteristics of a type, period, or method of construction; or representation of the work of a master; or possession of high artistic values; or representation of a significant and distinguishable entity whose components may lack individual distinction
- Criterion D (Information Potential). Properties that yield, or are likely to yield, information important in prehistory or history. Criterion D is most often (but not exclusively) associated with archaeological resources. To be considered eligible under Criterion D, sites must be associated with specific or

general patterns in the development of the region. Therefore, sites become significant when they are seen within the larger framework of local or regional development.

"Integrity" is perhaps the paramount qualification of NRHP eligibility, and can be related to any or all of the following (Andrus and Shrimpton 2002):

- Location: the place where the historic property (or properties) was/were constructed or where the historic event(s) occurred
- Design: the combination of elements that create the form, plan, space, structure, and style of a property (or properties)
- Setting: the physical environment of the historic property (or properties)
- Materials: the physical elements that were combined to create the property (or properties) during the associated period of significance
- Workmanship: the physical evidence of the crafts of a particular culture or people during any given period in history or prehistory
- Feeling: the property's (or properties') expression of the aesthetic or historic sense of the period of significance
- Association: the direct link between the important historic event(s) or person(s) and the historic property (or properties).

The four dams were evaluated in relation to these criteria and attributes, and then the criteria of adverse effect were applied for the proposed undertaking in accordance with ACHP regulations at 36 CFR 800.5. Specifically,

> An adverse effect is found when an undertaking may alter, directly or indirectly, any of the characteristics of a historic property that qualify the property for inclusion in the National Register in a manner that would diminish the integrity of the property's location, design, setting, materials, workmanship, feeling, or association. Consideration shall be given to all qualifying characteristics of a historic property, including those that may have been identified subsequent to the original evaluation of the property's eligibility for the National Register. Adverse effects may include reasonably foreseeable effects caused by the undertaking that may occur later in time, be farther removed in distance or be cumulative.

4. SURVEY RESULTS

This section presents the findings of the historic architectural investigation carried out for the Project. One resource, consisting of four low-head dams in the Grand River at Grand Rapids, known as Beautification Dams, was evaluated as part of the Section 106 review for the Project. The dams would be removed as part of the Project, and thus would be subject to direct effects from the Project.

4.1 Previous Investigations

A literature review of previously recorded resources determined that the Beautification Dams had not been previously recorded as historic resources. An Architectural Properties Identification Form was completed as part of the current investigations (Appendix A).

4.2 Current Survey Findings

The Beautification Dams consist of four low-head concrete dams ranging from 1.5 to 3 feet in height and approximately 425 to 440 feet in length, located in the Grand River between the Interstate 196 Bridge and the Pearl Street Bridge. The four dams together constitute the evaluated resource, and are collectively referred to as the Beautification Dams in the Grand River. They are recommended eligible for the NRHP and are summarized in Table 4.2-1. A view of each dam is shown in Figures 4.2-1 through 4.2-4.

Table 4.2-1: Summary of Beautification Dams in the Grand River

Number	Location	Length*	Height†
Dam #1	135–155 feet north of the center of the Bridge Street Bridge	437 feet	3 feet
Dam #2	148–175 feet south of the center of the Bridge Street Bridge	440 feet	1.5 feet
Dam #3	336–373 feet north of the center of the Gillette Pedestrian Bridge (Interurban Bridge)	440 feet	2 feet
Dam #4	85 feet north of the center of the Pearl Street Bridge	425 feet	1.5 feet

* Estimated length based on aerial photographs

4.2.1 Beautification Dams History

Low-head or low-stage dams typically run the width of a river or stream and allow the water flow to pass over all or most of its length. They can be as high as 15 feet, but are more commonly just a few feet in height. These types of dams are common throughout the United States and are usually constructed to raise the water level for civic, industrial, or agricultural use. They also enhance recreational opportunities. Many low-head dams were constructed across the U.S. in the eighteenth and nineteenth centuries to power gristmills and small industries (Tschantz and Wright 2011:8).

The use of low-head dams for beautification and recreation, rather than commercial and industrial uses, coincided with the emergence of city planning as a professional pursuit in the early twentieth century, and a shift in public attitudes toward the environment and the revitalization of urban areas through public improvement projects and regulatory policy (Hill 2000:153). Harland Bartholomew was a prominent city planner from the 1920s to the 1980s, known for advocating for zoning laws and creating the concept of the “City Efficient.” His firm, Harland Bartholomew & Associates (HB&A) developed more than 500 city plans and more than 300 zoning proposals for cities in the U.S. and internationally (Barone 2018:438).

Bartholomew began working on a plan for Grand Rapids as early as 1921 (GRPL 2017). His plan for Grand Rapids was based on similar principles to those he applied in other cities, both large and small. The plans were based on zoning, a concept that was being recognized by city leaders as the most efficient way to maintain property values and grow their cities in a controlled manner. Bartholomew’s zoning classes were based on variations on three factors: use, building height, and lot size. Industrial uses were zoned to the outskirts of the city, along rail lines and waterways, while the downtown area was designated for commercial use. Planning firms worked with city planning commissions to develop a plan that the commission could promote to city officials, civic groups, and business leaders. The planning commissions also worked to build public support for the plans. The goal was to get buy-in from a variety of interests in the city by highlighting the economic advantages that would accrue from a comprehensive zoning plan. In Grand Rapids, the City Planning Commission presented their early planning work at a municipal fair called “City Show” in 1920 (Moskowitz 1998:308–309).

Bartholomew produced a number of documents for the City of Grand Rapids between 1921 and 1927. His overall vision was presented to the public in 1924 through the *Grand Rapids Press* (1924a), which published a rendering of the “Future Grand Rapids” produced by Bartholomew (Figure 4.2-5). The Grand River occupied the prominent spot in the oblique aerial view and was flanked by a tree-lined esplanade on the east bank and a park with trees, open spaces, and walkways on the west bank. The bridge at the bottom of the drawing is the Bridge Street Bridge, with the next two bridges being the interurban rail bridge (Gillette Pedestrian Bridge) and the Pearl Street Bridge. No dams are evident in the view, but the river is full from bank to bank, with no obstructions. Eventually, the esplanade along the river was constructed in the form of the Riveredge Trail, and parks were established along the west side of the river, as envisioned in the plan. The changes proposed in the plan, including a “beautiful river front,” were praised by the paper as “outstanding” (Grand River Press 1924b).

Bartholomew’s City Plan for Grand Rapids included a section on riverfront improvement (Bartholomew 1925:100–103). He stated that the river was the city’s “raison d’etre,” but had fallen into insignificance in the commercial age. However, Bartholomew maintained that opportunities for development were available, and that the city should purchase as much of the riverfront property as possible. The flood walls in place along portions of the river were seen as a positive influence that would permit linear parks adjacent to the river. He recommended the construction of additional walls and the reclaiming land adjacent to the east side of the river that was occupied by the East Side Canal and constructing a road alongside the river. This would separate the buildings from the riverside docks and encourage more aesthetic architecture. The improvements would not interfere with the commercial or industrial activities of

the city, because the river no longer had value to those interests. The plan for the river was plainly laid out, including improving the appearance below the existing 6th Street dam:

> Grand Rapids must complete its flood wall as a protective measure. It would seem that this work would offer the best opportunity to carry out a more thorough riverfront improvement program. Not only should the banks be improved by the use of wall, terraces, small parks and plazas, but the appearance of the river below the dam should be improved. During the dry seasons certain stretches of the rapids have the appearance of an abandoned stone quarry overgrown with weeds and littered with tin cans, crates and rubbish. Several low-stage dams could be constructed at intervals which would maintain water constantly in the river. This would add greatly to the appearance and provide ample water surface for boating [Bartholomew 1925:102].

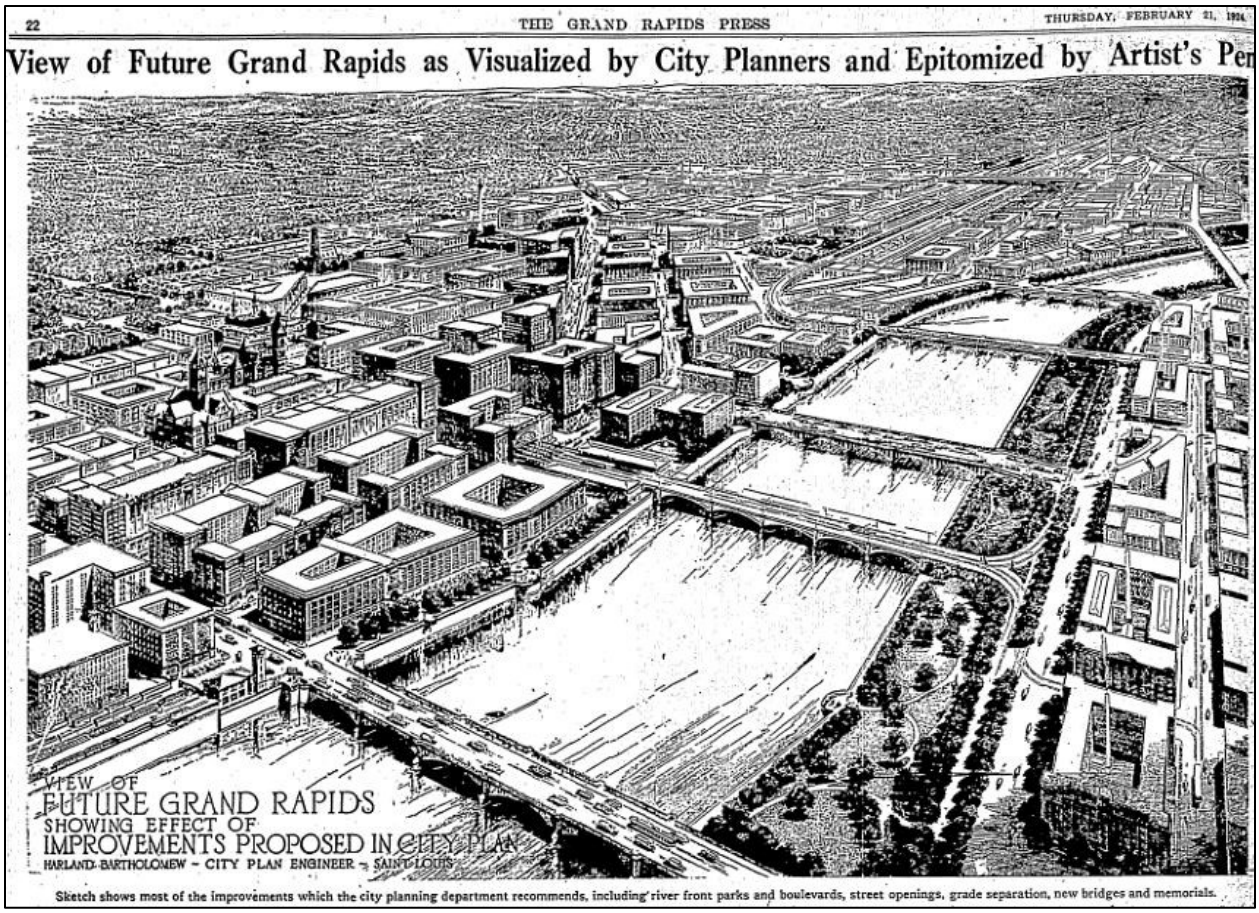

Figure 4.2-5: Artist Rendition of Harland Bartholomew's City Plan (1924)

In October 1925, the city reached an agreement with the Consumers Power Company (the former West Side Water Power Association) and the East Side Power Company to purchase the rights to the East Side Canal, which would be closed to form a sewer and a riverside park. The city had held an option on the rights to the canal for some time, and it appears that the acquisition of the property was part of the effort to carry out the plans for beautification of the river. The agreement stipulated that the city "reserved perpetual right to sufficient water for all city purposes, and that "sufficient water must be kept running over

the large dam to keep a series of smaller dams filled the year around" (*Grand Rapids Press* 1925). The story in the *Grand Rapids Press* stated that the city would keep the river clean, and "To this end it has secured the necessary options for construction of three dams, one just north of Bridge-st., one just south of Bridge-st., and third just north of Pearl-st., calculated to hold enough water to hide the ugly bottom, now strewn with all manner of debris and overgrown with weeds." According to the article, the "pretentious program of beautification, as sketched by Harland Bartholomew of St. Louis, city planning expert responsible for Grand Rapids' zoning ordinance, now approaches a step nearer realization."

The value of improving the river both economically and aesthetically was not lost on observers, even in the planning stages. The *Grand Rapids Press* noted of the plan in 1925 that, "Advantage will be taken of the open sloping west bank, which now is a mass of weeds, and a modest program of landscaping and care is expected to do wonders." The acquisition of the canal land allowed for a reorganized street plan and the availability of valuable land. "When this wilderness of rubbish, old iron and decrepit buildings has been cleared away the increased value of the property, according to the analysis of [assistant to the city's consulting engineer] Mr. Tenlloor, will have justified the trouble, and the city will be rid of perhaps its greatest fire menace" (*Grand Rapids Press* 1925).

The original plan apparently included five dams, but only four were constructed due to water rights of the last user of the West Side Canal for a water wheel (*Grand Rapids Press* 1927a, 1928b). The city appropriated $7,500 in March of 1926 for "…beautification of Grand River through the erection of dams intended to create a greater depth of water inside the city limits" (*Grand Rapids Press* 1926). However, it was not until May of 1927 that a bid was accepted for the project. The $24,000 bid of Peninsular Construction Company of Grand Rapids was over the city's estimate for the work, but was less than the only other bid received. The plans at that time were for the dams to be constructed of concrete and approximately 470 feet long. The dams were to be located 100 feet north of Bridge Street, 36 feet south of Bridge Street, at Brumrich Street, 50 feet north of Pearl Street, and 35 feet south of Pearl Street (*Grand Rapids Press* 1927a). The locations given approximate the final placements, which are detailed in Table 4.2-1.

Profile plans of the dams are shown in Figure 4.2-6 (GRCARC ca. 1927). It is not clear if the dams were built to these exact specifications, as no as-built drawings have been located. The profiles indicate that Dam #1 would have a height of 3 feet, Dam #2 and Dam #4 would be 1.5 feet high, and Dam #3 and Dam #5 would each be 2 feet high. Dam #5 was eventually dropped from the plan. A profile map of the river made in 1928 indicates that the actual dams were lower (GRCARC 1928). Current elevations taken across the dams show irregular heights across the width of the dams and only about a 1–1.5-foot drop between them. This may be due to erosion of the tops of the dam as a result of water scouring. The profiles in Figure 4.2-6 show a typical low-head concrete dam shape that has a slightly sloping upstream face with a beveled cap and a ramp-like downstream face to break the fall of the water. Each dam would have a flap or drain valve at the base. Figure 4.2-7 shows the profile of the dams after construction, which is consistent with the plans. The valve appears to have been constructed as a gated opening rather than an outlet in the base of the dam, as can be seen in Figure 4.2-8.

Work on the coffer dam to divert the river during construction began by July 1927 (*Grand Rapids Herald* 1927). As noted above, the dams were completed on schedule by January 1, 1928, although the $37,000 cost was considerably more than the $24,000 bid. Figure 4.2-9 shows Dam #1 after construction, looking north, with the Sixth Street Dam in the background.

4.2.2 Beautification Dams: Architectural Description and Evaluation

The Beautification Dams in the Grand River are four low-head, concrete dams that run the width of the river in downtown Grand Rapids. They vary in height from 1.5 to 3 feet, and in length from approximately 425 feet to 440 feet. They are anchored in bedrock to a depth of approximately 1 foot. Historical drawings and photographs indicate that a gated opening was located in each dam, but the nature and location of these openings in the current dams is not clear due to the dams being obscured by water. The dams have the same basic profile as shown in Figures 4.2-6 and 4.2-7. The form and construction technique is typical of low-head dams constructed throughout the United States during the period.

NRHP Evaluation: ERM recommends that the Beautification Dams in Grand River are potentially eligible for the NRHP under Criterion A for their association with events important to the history of Grand Rapids. The dams reflect efforts in the early twentieth century to improve the city through planning, zoning, and public works projects. The result was a shift in the orientation of the downtown area to embrace the river as an attraction for enjoyment and recreation. Parks and trails were established along the banks, and new buildings were constructed with an emphasis on attractive architecture that encouraged public use of the surrounding spaces. ERM recommends that the dams are also significant under Criterion B for their association with Harland Bartholomew, one of the most influential city planners of the twentieth century.

Beginning in St. Louis in 1916, Bartholomew and his firm developed plans for hundreds of cities, influencing zoning decisions and promoting urban renewal and beautification. Bartholomew's plan for Grand Rapids specifically called for the installation of the dams, which consequently influenced the development of the downtown area in the way in which he intended. Although the Beautification Dams retain sufficient architectural integrity to convey the resources' historical significance, their design is utilitarian and common to contemporary structures across the country. As a result, they do not represent exceptional design or engineering and do not constitute an outstanding example of architecture associated with historic water control features. Therefore, ERM recommends the Beautification Dams in Grand River are not potentially eligible for the NRHP under Criterion C. For similar reasons, ERM recommends that the dams are not likely to yield information important to history and are thus not potentially eligible under Criterion D.

Assessment of Effects: The function of the Beautification Dams would not be retained as a result of their removal, although the Project is intended to restore the beauty of the original rapids that once characterized the river. The placid, quiet waters created by the dams would be replaced by faster moving water that would create a different atmosphere than that which characterized the river between 1927 and the present. Although the goal of the Project, in part, is similar to that of the 1925 Bartholomew plan in making the river attractive for expanded recreation and use, the nature of the experience for those using the river space would be different from that intended by Bartholomew. Therefore, it is ERM's opinion that the proposed removal of the dams would compromise the character-defining features of the dams that make them historically significant, and the action would constitute an adverse effect.

5. CONCLUSION AND RECOMMENDATIONS

ERM conducted an evaluation of the NRHP eligibility of four low-head dams in the Grand River in Grand Rapids, which would be affected by the Grand Rapids Whitewater Project. With the support of the City of Grand Rapids and GRWW, ERM prepared this report evaluating whether the beautification dams constructed along the Grand River in the early twentieth century are potentially eligible for the NRHP, and if so, whether removal of the dams as part of the Project would result in adverse effects to these cultural resources. The findings of the current study are intended to support the Section 106 review of the proposed undertaking, which is subject to funding by the NRCS.

Based on the information gathered and presented here, ERM recommends that the four low-head dams, referred to as the Beautification Dams in Grand River, are potentially eligible for the NRHP. The dams meet the requirements for listing under Criterion A for their role in the emergence of city planning and the development of the riverfront as a focal point of downtown development in Grand Rapids, and under Criterion B for their association with city planner Harland Bartholomew, whose ideas on city beautification influenced the development of Grand Rapids during the twentieth century. Although the Beautification Dams retain sufficient architectural integrity to convey their historical significance, their design is utilitarian and common to contemporary structures across the country, and is not likely to yield information important to history. Therefore, ERM recommends that the Beautification Dams are not potentially eligible for the NRHP under Criteria C and D.

The function of the Beautification Dams to maintain water levels across the width of the Grand River would not be retained as a result of their removal. Although the goal of the Project, in part, is similar to that of the 1925 Bartholomew plan in making the river attractive for expanded recreation and use, the nature of the experience for those using the river space would be different from that intended by Bartholomew. Therefore, it is ERM's opinion that the proposed removal of the dams would compromise the character-defining features of the dams that make them historically significant, and the action constitutes an adverse effect. The Project plan as currently proposed requires removal of all of the dams and does not allow for avoidance or minimization of adverse effects. It is ERM's recommendation that, should MI SHPO concur with this assessment, a plan be developed to mitigate the adverse effects of the Project.

Narrative Architectural Description

Provide a detailed description of the property, including all character-defining features and any accessory resources. This is required for all properties.

The Beautification Dams in the Grand River are four low-head, concrete dams that run the width of the river in downtown Grand Rapids. They vary in height from 3 feet to 1.5 feet, and in length from approximately 425 feet to 440 feet. They are anchored in bedrock to a depth of approximately 1 foot. The only feature of the dams is an opening, presumably for flow and debris control. The dams have the same basic profile. The form and construction technique is typical of low-head dams constructed throughout the United States during the period.

History of the Resource

Provide information on previous owners, land use(s), and construction and alteration dates in a narrative format. This is required for all intensive level surveys, NRPQs, and nominations, and recommended for other identification efforts.

(see Figures at end of form)

Low-head or low-stage dams typically run the width of a river or stream and allow the water flow to pass over all or most of its length. They can be as high as 15 feet, but are more commonly just a few feet in height. These types of dams are common throughout the United States and are usually constructed to raise the water level for civic, industrial, or agricultural use. They also enhance recreational opportunities. Many low-head dams were constructed across the U.S. in the eighteenth and nineteenth centuries to power gristmills and small industries (Tschantz and Wright 2011:8).

The use of low-head dams for beautification and recreation, rather than commercial and industrial uses in the early twentieth century coincided with the emergence of city planning as a professional pursuit, and a shift in public attitudes toward the environment and the revitalization of urban areas through public improvement projects and regulatory policy (Hill 2000:153). Harland Bartholomew was a prominent city planner from the 1920s to the 1980s, known for advocating for zoning laws and creating the concept of the “City Efficient.” His firm, Harland Bartholomew & Associates (HB&A) developed more than 500 city plans and more than 300 zoning proposals for cities in the U.S. and internationally, making it likely the largest city planning firm in the country (Barone 2018:438).

Bartholomew began working on a plan for Grand Rapids as early as 1921 (GRPL 2017). His plan for Grand Rapids was based on similar principles to those he applied in other cities, both large and small. The plans were based on zoning, a concept that was being recognized by city leaders as the most efficient way to maintain property values and grow their cities in a controlled manner. Bartholomew’s zoning classes were based on variations on three factors: use, building height, and lot size. Industrial uses were zoned to the outskirts of the city, along rail lines and waterways, while the downtown area was designated for commercial use. Planning firms worked with city planning commissions to develop a plan that the commission could sell to city officials, civic groups, and business leaders. The planning commissions also worked to build public support for the plans. The goal was to get buy-in from a variety of interests in the city by highlighting the economic advantages that would accrue from a comprehensive zoning plan. In Grand Rapids, the City Planning Commission presented their early planning work at a municipal fair called “City Show” in 1920 (Moskowitz 1998:308–309).

Bartholomew produced a number of documents for the City of Grand Rapids between 1921 and 1927. His overall vision was presented to the public in 1924 through the *Grand Rapids Press* (1924a), which published a rendering of the “Future Grand Rapids” produced by Bartholomew (Figure 1). The Grand River occupied the prominent spot in the oblique aerial view and was flanked by a tree-lined esplanade on the east bank and a park with trees, open spaces, and walkways on the west bank. The bridge at the bottom of the drawing is the Bridge Street Bridge, with the next two bridges being the interurban rail bridge (Gillette Pedestrian Bridge) and the Pearl Street Bridge. No dams are evident in the view, but the river is full from bank to bank, with no obstructions. Eventually, the esplanade

along the river was constructed in the form of the Riveredge Trail, and parks were established along the west side of the river, as envisioned in the plan. The changes proposed in the plan, including a "beautiful river front," were praised by the paper as "outstanding" (Grand River Press 1924b)

Bartholomew's City Plan for Grand Rapids included a section on riverfront improvement (Bartholomew 1925:100–103). He stated that the river was the city's "raison d'etre," but had fallen into insignificance in the commercial age. However, Bartholomew maintained that opportunities for development were available, and that the city should purchase as much of the riverfront property as possible. The flood walls in place along the river were seen as a positive influence that would permit linear parks adjacent to the river. He recommended reclaiming land adjacent to the east side of the river that was occupied by the East Side Canal and constructing a road alongside the river. This would separate the buildings from the riverside docks and encourage more aesthetic architecture. The improvements would not interfere with the commercial or industrial activities of the city, because the river no longer had value to those interests. The plan for the river was plainly laid out:

> Grand Rapids must complete its flood wall as a protective measure. It would seem that this work would offer the best opportunity to carry out a more thorough riverfront improvement program. Not only should the banks be improved by the use of wall, terraces, small parks and plazas, but the appearance of the river below the dam should be improved. During the dry seasons certain stretches of the rapids have the appearance of an abandoned stone quarry overgrown with weeds and littered with tin cans, crates and rubbish. Several low-stage dams could be constructed at intervals which would maintain water constantly in the river. This would add greatly to the appearance and provide ample water surface for boating. (Bartholomew 1925:102)

In October 1925, the city reached an agreement with the Consumers Power Company (the former West Side Water Power Association) and the East Side Power Company to purchase the rights to the East Side Canal, which would be closed to form a sewer and a riverside park. The city had held an option on the rights to the canal for some time, and it appears that the acquisition of the property was part of the effort to carry out the plans for beautification of the river. The agreement stipulated that the city "reserved perpetual right to sufficient water for all city purposes,"…and that "sufficient water must be kept running over the large dam to keep a series of smaller dams filled the year around" (*Grand Rapids Press* 1925). The story in the *Grand Rapids Press* stated that the city would keep river clean, and "To this end it has secured the necessary options for construction of three dams, one just north of Bridge-st., one just south of Bridge-st., and third just north of Pearl-st., calculated to hold enough water to hide the ugly bottom, now strewn with all manner of debris and overgrown with weeds." According to the article, the "pretentious program of beautification, as sketched by Harland Bartholomew of St. Louis, city planning expert responsible for Grand Rapids' zoning ordinance, now approaches a step nearer realization."

The value of improving the river, both economically and aesthetically was not lost on observers, even in the planning stages. The *Grand Rapids Press* noted of the plan in 1925 that, "Advantage will be taken of the open sloping west bank, which now is a mass of weeds, and a modest program of landscaping and care is expected to do wonders." The acquisition of the canal land allowed for a reorganized street plan and the availability of valuable land. "When this wilderness of rubbish, old iron and decrepit buildings has been cleared away the increased value of the property, according to the analysis of [assistant to the city's consulting engineer] Mr. Tenlloor, will have justified the trouble, and the city will be rid of perhaps its greatest fire menace" (*Grand Rapids Press* 1925).

The original plan apparently included five dams, but only four were constructed due to water rights of the last user of the West Side Canal for a water wheel (*Grand Rapids Press* 1927a, 1928b). The city appropriated $7,500 in March of 1926 for "…beautification of Grand River through the erection of dams intended to create a greater depth of water inside the city limits" (Grand Rapids Press 1926). However, it was not until May of 1927 that a bid was accepted for the project. The $24,000 bid of Peninsular Construction Company of Grand Rapids was over the city's estimate for the work, but was less than the only other bid received. The plans at that time were for the dams to be constructed of concrete and approximately 470 feet long. The dams were to be located 100 feet north of Bridge Street, 36 feet south of Bridge Street, at Brumrich Street, 50 feet north of Pearl Street, and 35 feet south of Pearl Street (*Grand Rapids Press* 1927a).

Profiles plans of the dams are shown in Figure 2 (GRCARC ca. 1927). It is not clear if the dams were built to these

exact specifications, as no as-built drawings have been located. The profiles indicate that Dam #1 would have a height of 3 feet, Dam #2 and Dam #4 would be 1.5 feet high, and Dam #3 and Dam #5 would each be 2 feet high. Dam #5 was eventually dropped from the plan. A profile map of the river made in 1928 indicates that the actual dams were lower (GRCARC 1928). Current elevations taken across the dams show irregular heights across the width of the dams and only about a 1–1.5-foot drop between them. This may be due to erosion of the tops of the dam as a result of water scouring. The profiles in Figure 2 show a typical low-head concrete dam shape that has a slightly sloping upstream face with a beveled cap and a ramp-like downstream face to break the fall of the water. Each dam would have a flap or drain valve at the base. Figure 3 shows the profile of the dams after construction, which is consistent with the plans. The valve appears to have been constructed as a gated opening rather than an outlet in the base of the dam, as can be seen in Figure 4.

Work on the coffer dam to divert the river during construction began by July 1927 (*Grand Rapids Herald* 1927). As noted above, the dams were completed on schedule by January 1, 1928, although the $37,000 cost was considerably more than the $24,000 bid. Figure 5 shows Dam #1 after construction, looking north, with the Sixth Street Dam in the background.

Statement of Significance/Recommendation of Eligibility

Provide a detailed explanation of the property's eligibility for the National Register. Include an evaluation under at least one of the four National Register Criteria and one Area of Significance. Include a discussion of the seven aspects of integrity, and make a recommendation about eligibility. This is required for all properties.

The Beautification Dams retain integrity of location, as they have not moved from their original location. In addition, the associated bridges and the river have remained unchanged, and most of the buildings surrounding the dams are original to the construction of the dams, which means the dams still retain integrity of setting. The Beautification Dams do retain their design and material integrity as no alterations to the utilitarian structures are known. Furthermore, the dams retain integrity of workmanship and association as a structure that conveys the craftsmanship of a utilitarian design tied to water control and public works improvement projects. Finally, the Beautification Dams retain integrity of feeling when viewed as a whole, with the river and surrounding bridges. For these reasons, ERM recommends that the Beautification Dams in Grand River are potentially eligible for the NRHP under Criterion A for their association with events important to the history of Grand Rapids. The dams reflect efforts in the early twentieth century to improve the city through planning, zoning, and public works projects. The result was a shift in the orientation of the downtown area to embrace the river as an attraction for enjoyment and recreation. Parks and trails were established along the banks, and new buildings were constructed with an emphasis on attractive architecture that encouraged public use of the surrounding spaces. ERM recommends that the dams are also significant under Criterion B for their association with Harland Bartholomew, one of the most influential city planners of the twentieth century. Beginning in St. Louis in 1916, Bartholomew and his firm developed plans for hundreds of cities, influencing zoning decisions and promoting urban renewal and beautification. Bartholomew's plan for Grand Rapids specifically called for the installation of the dams, which consequently influenced the development of the downtown area in the way in which he intended. Although the Beautification Dams retain sufficient architectural integrity to convey the resources' historical significance, their design is utilitarian and common to contemporary structures across the country. As a result, they do not represent exceptional design or engineering and do not constitute an outstanding example of architecture associated with historic water control features. Therefore, ERM recommends the Beautification Dams in Grand River are not potentially eligible for the NRHP under Criterion C. For similar reasons, ERM recommends that the dams are not likely to yield information important to history and are thus not potentially eligible under Criterion D.

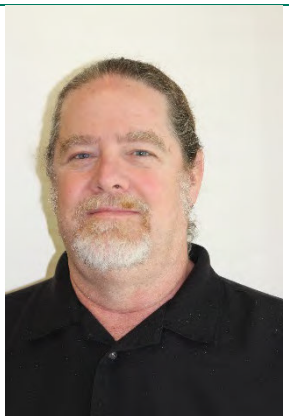
APPENDIX B RESUMES

Jeffrey L. Holland

Historian

Mr. Holland has over 30 years of experience on Cultural Resources Management projects throughout the eastern United States, the Midwest, and Texas. He has conducted historical research and documentation for National Register properties and districts, HABS/HAER recordation, Assessments of Effects reports, and cultural resources survey, testing, and data recovery projects. He has also authored popular histories for major industrial facilities and summaries of archaeological projects for public education. Mr. Holland's specialties include slavery, African American history, nineteenth century agriculture, the Civil War, and the history of military installations, utilities, and infrastructure in the twentieth century.



Experience: 30+ years' experience in Section 106, NEPA, and Historic Preservation Planning for government, energy, and industrial sectors

Key Projects at ERM

Energy Client, Pipeline Project, 2015–2019
Conducted cultural resource investigations as part of the permitting of a 600-mile natural gas pipeline in three states. Prepared historical contexts, conducted research on properties, assessed effects of project on resources, prepared mitigation plans for NRHP-eligible properties. Federal Energy Regulatory Commission issued Programmatic Agreement approving implementation of mitigative measures to complete compliance with Section 106 of the National Historic Preservation Act.

Energy Client, Wind Energy Project, 2019–2020
Prepared a Cumulative Visual Effects Assessment for a proposed off-shore wind energy installation of 800-megawatts in the waters of Rhode Island and Massachusetts. The analysis incorporated 17 lease areas and 761 wind generating turbines from the proposed project and reasonable foreseeable future projects. The assessment focused on three historic properties, including a Traditional Cultural Property and a National Historic Landmark.

Energy Client, Wind Energy Project, 2017–2019
Developed context and assessed historic significance for resources in three county area of northeast Pennsylvania that might be affected by a series of proposed wind turbines sites. The context addressed thematic resource types of primary significance in the region including coal industry related sites, railroads, and agricultural properties.

Energy Client, NRHP Evaluation of LNG Terminal, 2019
Developed context and assessed historical significance of an LNG terminal in Alaska completed in 1969 that was the first to export LNG from the United States. The research addressed the process involved in liquefying natural gas and changes to the plant over time. The plant was recommended as eligible for the NRHP.

Energy Client, NRHP Evaluation of Abandoned Pipeline, 2018
Served as author of reports for four western states assessing the historical significance of a 700-mile former oil pipeline converted to natural gas that was slated for abandonment. The assessment was conducted in accordance with a Notice of Exemption issued by the Advisory Council on Historic Preservation regarding abandoned historic natural gas pipelines.

Manufacturing Client, NRHP Evaluation of Historic Orchard Property, 2018
Conducted historical research and produced historical context for historic apple orchard and other historic properties in Jefferson County, West Virginia. Assessed significance of properties and potential direct and visual effects of a fiber manufacturing facility.

Energy Client, Wind Energy Project, 2016–2017
Developed context and assessed historic significance for resources in four county area of northeast West Virginia that might be affected by a series of proposed wind turbines sites. The context addressed a number of resource types including historic coaling and lumber communities, railroads, and industrial sites. Assessed architectural resources for NRHP eligibility under Criteria A and B through local history sources, deed research, and genealogy. Prepared inventory forms for data entry.

Key Projects Prior to Joining ERM

Energy Client, NRHP Documentation, 2014
Researched the ownership history and development of the William Evans farmhouse and associated buildings using county records, historical maps, census returns, and other primary and secondary sources as part of a Memorandum of Agreement to mitigate the effects of a transmission line with a permanent archival record of the property

Government Agency, Nuclear Power Program History, 2013
Conducted historical research using documents from the agency's corporate libraries, records in the National Archives, contemporary newspaper articles, and secondary sources on the nuclear power industry to produce a fully-referenced, illustrated history of what was for many years the nation's largest nuclear power program. The agency commissioned this historical overview of its nuclear power program to provide a concise reference for the agency.

Government Agency, HABS Documentation, 2012
Examined project records and historic photographs, along with other primary and secondary sources to establish the history of the former project offices of the Falcon Dam Project on the Rio Grande, constructed in 1951.

Government Agency, NRHP Assessment, Levees and Water Control Features, 2010–2011
Researched the records of the U.S. Boundary and Waters Commission and the Bureau of Reclamation to assess the significance of two levees constructed on the Rio Grande to control flooding. The levees interfaced with irrigation systems constructed prior to the levees, which also had historic features.

Government Agency, Oral History Documentation of Federal Housing Project, 2009
Conducted historical research on two housing projects slated for demolition using records at the local historical societies and libraries. Current residents of the developments were interviewed about their experiences in public housing. The documentation was part of a recordation of the two facilities intended to produce a comprehensive history of the public housing prior to the sale of the properties by the city.

Energy Client, Pipeline Project, 2008
Produced statewide contexts for five states, as well as more specific histories for dozens of counties and parishes along a 507-mile natural gas transmission pipeline in the southeast U.S. Historical research was also conducted on identified architectural resources to aid the assessment of their NRHP significance. The project was conducted on a short time schedule.

Military Agency, Air Force Facility History, 2006
Served as Historian and Author for the production of a pictorial history of Air Force Plant 6, an aircraft assembly plant operated by Bell Aircraft Company during World War II and later by Lockheed Aeronautics Company and its successors. The book is a fully-illustrated, perfect-bound history of the plant intended for a general audience and was distributed to libraries, government agencies, and other interested organizations.

Government Agency, Cultural Resources Survey of Redevelopment Property, 2006
Researched agency records and photographs on site and at the National Archives Southeast Region Branch in Atlanta, as well as local facilities to document the history and historic significance of a portion of the agency's reservation. The site included numerous industrial properties related to weapons manufacture in World War I, New Deal agricultural programs, and hydroelectric power. The assessment of the facilities was later used to develop an adaptive reuse plan for the property.

Government Agency, Archaeological Data Recovery in Historic District, 2006
Served as a Historian for this investigation of two blocks of a commercial and residential street in a historically black neighborhood of Savannah, Georgia. Using Sanborn Fire Insurance maps, city directories, and a variety of historical sources, documented neighborhood development, racial and social composition, and landscape characteristics over a period of approximately 100 years. The information was applied to the archaeological evidence from the excavation of features related to domestic and business activities on the street during the early twentieth century. A popular pamphlet on the results of the investigation was also produced.

Government Agency, Historical Research for NRHP Historic District Nomination, 2005
Conducted background research on the history of town in West Georgia, the evolution of the built environment within the district, and the construction date of the buildings, as part of a survey of 60+ properties for this historic downtown historic district. The information was used for an NRHP nomination submitted to the Georgia SHPO, and the district was listed in 2007.

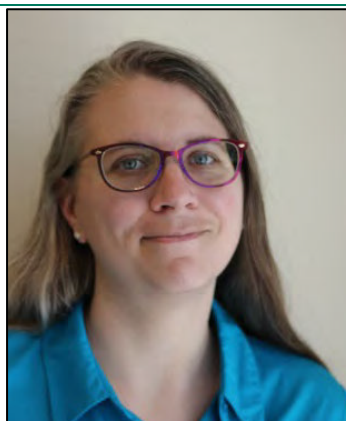
Energy Client, NRHP Assessment of Hydroelectric Power System, 2004
This project involved a review of historical documents related to the design and construction of 11 dams and powerhouses along two major rivers in North and South Carolina. Published histories, company documents, contemporary accounts were consulted, and similar large-scale power and flood-control projects in the Southeast and in the United States were studied to assess the significance of a series pf projects that spanned two states and included multiple facilities along an entire river system.

Military Agency, Context and NRHP Assessment of Korean War and Cold War Structures, 2003
Conducted background research to develop historic contexts to aid in the interpretation and assessment of BASOPS structures from the Korean War and Cold War periods at Fort Bliss and Briggs Army Airfield, Texas. The assessment of the facilities required the application of NRHP guidelines for properties of exceptional significance but less than 50 years old.

Emily Tucker-Laird

Senior Architectural Historian and Archaeologist

Ms. Tucker-Laird is Secretary of the Interior Qualified as an architectural historian and archaeologist. Emily is based in ERM's Duluth Georgia office, and attached to the cultural resources field services group. Emily has extensive experience working as a Principal Investigator. Her projects have included intra and interstate pipelines, electrical transmission lines, wind projects, solar projects, microwave towers, and treatment plans. In addition to fieldwork, Emily has experience supervising and coordinating for complex projects, and developing treatment plans for historic property concerns. Emily's has consulted with a wide range of state and federal agencies, as well as local stakeholders and interested parties.



Experience: 15 years of experience in the field of Cultural Resource Management

Key Projects

Energy Client, Wind Project, 2016
Architectural historian 2016 for a 72-turbine wind project in Grant and Tucker County West Virginia. Key tasks included field survey and reporting, and analysis of visual simulations. Project met the requirements of the West Virginia Public Service Commission, and Section 106.

Energy Client, Pipeline Project, 2015-present
600-mile-long natural gas pipeline extending from West Virginia to North Carolina. Architectural Historian and Principal Investigator for historic architecture survey and assessment of effects and Historic Architecture Task Manager responsible for overseeing treatment plans to mitigate project effects. Task Manager for FCC tasks. Responsibilities also include consultations with the FERC, SHPO, and consulting parties.

Energy Client, Transmission Line Project, 2017
Six transmission line alternatives in Fairfax County, Virginia. Cultural resource specialist who prepared sections of the routing study, SCC application, and pre-application analysis, and conducted the technical review for the cultural resource investigations conducted for a proposed line to be sited in northern Virginia.

Energy Client, Pipeline Project, 2016
Architectural Historian for a 96-mile natural gas pipeline in Calcasieu, Jefferson Davis, Acadia, and Evangeline parishes. Completed architectural survey to meet the requirements of the FERC and LASHPO.

Telecommunications Client – Nationwide 2014-2015
Architectural Historian and Archaeologist for a nationwide NEPA Program Management Team serving a major national telecommunications carrier. Provide QA/QC oversight on cultural resources submittals and client deliverables. Tasks include assuring that all compliance submittals conform to regulatory requirements as well as meeting client standards, and assuring that required documentation of compliance is included in all client deliverables.

Key Projects before Joining ERM

Energy Projects, 2012
Muscle Shoals Reservation, Alabama: Architectural Historian for the HABS Level II documentation of selected resources of the Tennessee Valley Authority Muscle Shoals Reservation. The architectural survey included a detailed survey of both the interior and exterior of 20 resources. Final products included a photographic record, historical context of each resource, and architectural descriptions.

City Planning Project, 2010
Georgetown, SC Historic District Survey: One of a team of Architectural Historians recording 900 resources within the National Register-listed historic district. Final products included a comprehensive historic district inventory, maps which identified building by period of construction and contributing status, South Carolina Department of Archives and History Intensive-level historic structure forms and photographs, and a report.

Macon Cemetery Preservation Corporation, 2007
Cemetery Preservation Plan in Georgia: Architectural Historian for a conditions assessment of the 13-acre Linwood Cemetery. Containing over 4,000 burials. Identified the extent of interments, overall conditions across the cemetery, and specific graves and markers requiring repair and stabilization. The product of the work was an assessment of the cemetery's condition and a preservation plan.

Energy Client, Lateral Pipeline Project, 2013-2015
75-mile crude oil pipeline in Illinois and Indiana: Principal Investigator for historic structures, Field Director and Crew Coordinator for the project. Managed several crews, and subcontractors, met with the land office to determine what was available for survey, and acted as the health and safety officer.

MICHIGAN ABOVE-GROUND SURVEY MANUAL

UPDATED BY
KATIE KOLOKITHAS AND DIANE TUINSTRA

2018

STATE HISTORIC PRESERVATION OFFICE

ACKNOWLEDGMENTS

The creation of this 2018 version of the Michigan Above-Ground Survey Manual, published by the State Historic Preservation Office (SHPO), was a joint effort between Katie Kolokithas, survey and information coordinator, and Diane Tuinstra, inventory coordinator. This manual is an update of the 2001 manual written by Robert O. Christensen and Barbara Wyatt. Much of the text from that manual remains. Many thanks are given to Mr. Christensen and Ms. Wyatt, plus the other individuals who contributed to that manual's creation. Laura Rose Ashlee edited the entire manual as well as offered helpful suggestions on examples and content. Photographs used in the manual come from the Michigan SHPO's statewide inventory.

This manual has been financed in part with federal funds from the National Park Service, U.S. Department of the Interior. However, the contents and opinions do not necessarily reflect the views or policies of the Department of the Interior.

This program receives federal financial assistance for identification and protection of historic properties. Under Title VI of the Civil Rights Act of 1964 and Section 504 of the Rehabilitation Act of 1973, and the Age Discrimination Act of 1975, as amended, the Department of the Interior prohibits discrimination on the basis of race, color, national origin, or disability or age in its federally assisted programs. If you believe you have been discriminated against in any program, activity, or facility as described above, or you desire further information, please write to:

Chief, Office of Equal Opportunity Programs United States Department
of the Interior National Park Service
1849 C Street, NW
Washington, DC 20240

THE MICHIGAN ABOVE-GROUND SURVEY PROGRAM

INTRODUCTION

This manual provides standards and guidelines for conducting surveys of above-ground historic resources in Michigan. The State Historic Preservation Office (SHPO) recommends that this manual guide those individuals planning and carrying out surveys and requires compliance with the requirements identified in this manual for projects funded by SHPO grant funding or requiring review or approval from SHPO. This manual provides information regarding approaches to identification, documentation, and evaluation of historic above-ground sites, buildings, and features in accordance with the *Secretary of the Interior's Standards for Identification, Evaluation, and Preservation Planning*. This manual is designed to provide guidance for all types of above-ground surveys, including:

- Surveys funded by the federal Historic Preservation Fund and administered by the State of Michigan;
- Surveys required by the State Historic Preservation Office (SHPO) under Section 106 of the National Historic Preservation Act; and
- Surveys intended to provide an informational database for the establishment of local historic districts under Michigan's local historic districts enabling act, Public Act 169 of 1970, as amended, or for other preservation planning purposes, including preparation of National Register of Historic Places nominations.

This manual does not provide instruction for archaeological surveys. For information about archaeological surveys, please contact SHPO's archaeologists at 517-373-1618.

SURVEY IN MICHIGAN

The Michigan statewide survey program was started in the late 1960s under the direction of SHPO, but with the participation of numerous partners including local communities, regional planning agencies, and citizens around the state. In the 1980s, SHPO created *Surveying Michigan's Historic and Architectural Resources: A How-To Guide*, which directed the survey program for a number of years. In the 1990s, a series of eight survey manuals were used as the guide for the program. In 2001 a new survey manual was written by Robert Christensen and Barbara Wyatt called *Manual for Historic and Architectural Surveys in Michigan*. This 2018 manual replaces the 2001 manual.

In 2016 the Michigan SHPO initiated a project to make the survey data collected over the past fifty years more accessible to the public by creating a GIS-based program to collect, store, and map data. The project, called MiSHPO, will allow for online submission of survey reports and data as well as Section 106 applications, National Register nominations, and more. When MiSHPO is complete and ready to accept online submission of surveys, this manual will be updated with the necessary information to guide the electronic submission of surveys through that portal.

RECONNAISSANCE-LEVEL AND INTENSIVE-LEVEL SURVEYS

Survey refers to the process of identifying and gathering data on a community's historic resources. There are two main types of survey for above-ground resources: Reconnaissance-level and Intensive-level Survey. Survey can include field survey, the physical search for and recordation of historic properties; background research to establish historic context for the properties within the project area; and historical research on surveyed properties. The final products of a survey should include the following:

- Survey Report
- Color-photographs of the historic properties
- Inventory or data information on each property

Reconnaissance-level survey identifies properties of architectural significance and updates existing information in SHPO files. The reconnaissance survey documents properties using photographs, brief descriptions, condition, and location information. Limited research on the history of the buildings, sites, and features is undertaken. Reconnaissance-level surveys look primarily at the architectural integrity of the properties or National Register criteria C. This type of survey is the first step in the preservation planning process and can be undertaken in a limited or broad geographic area. The products of a reconnaissance-level survey include information entered into the survey report, survey forms, and the MiSHPO system. Reconnaissance-level surveys should be used as a means to determine where to focus intensive-level survey efforts.

Intensive-level survey seeks to identify and thoroughly document significant properties and districts through research and evaluation of the National Register of Historic Places criteria within the broader historic context. Intensive-level surveys are more complex, time-consuming, and represent a larger financial commitment for a community. These surveys also provide the most detailed information about an area's history and historic properties. Intensive-level survey begins with a reconnaissance survey or an update of an older survey. The survey then continues with research on potentially significant properties using primary sources, researching the community history, evaluating the properties for National Register significance, identifying historic districts, and completing MiSHPO submission information. Finally, many intensive-level surveys provide recommendations for future preservation activities.

PURPOSE OF SURVEY

The National Historic Preservation Act of 1966, as amended, requires all SHPOs to direct and conduct survey. The act states, "It shall be the responsibility of the State Historic Preservation Officer to administer the State Historic Preservation Program and to—in cooperation with Federal and State agencies, local governments, and private organizations and individuals—direct and conduct a comprehensive statewide survey of historic properties and maintain inventories of such properties."

Survey can serve many purposes including but not limited to the following:

- To provide a basis for local planning
- To provide data to support locally designated historic districts, National Register of Historic Places districts, or individual property designations
- To comply with environmental review requirements under Section 106 of the National Historic Preservation Act
- To achieve or maintain Certified Local Government (CLG) status
- To develop heritage tourism initiatives
- To provide information for thematic studies
- To provide a permanent record for the future

FREQUENTLY ASKED QUESTIONS ABOUT SURVEY

WHAT IS THE DIFFERENCE BETWEEN A RECONNAISSANCE-LEVEL SURVEY AND AN INTENSIVE-LEVEL SURVEY?

A reconnaissance-level survey identifies properties based on their architectural significance and provides basic property information for SHPO files. Reconnaissance surveys include limited historical research on the individual buildings and are used as a tool to determine where to concentrate more intensive research. Intensive-level survey seeks to identify and thoroughly document properties and districts through research and evaluation of the National Register criteria. These surveys provide a more extensive context for the area and research on each individual building.

SHOULD WE DO A RECONNAISSANCE-LEVEL SURVEY OR AN INTENSIVE-LEVEL SURVEY?

The purpose of the survey helps to determine the appropriate level of research. Reconnaissance-level surveys are a good first step and preservation planning tool while intensive-level surveys provide a more complete picture of the surveyed area. Determination of the level of review required for your project can be made through consultation with SHPO.

THERE ARE TREES/BRUSH/UTILITY LINES BLOCKING MY PHOTOGRAPH, WHAT SHOULD I DO?

We ask surveyors to do their best to take photographs without obstructions such as vegetation and utility lines, but we understand that in certain conditions obtaining a good photograph of a building may be difficult. Surveys should be conducted in the spring or fall when the leaves are not on the trees. If the surveyor is not able to obtain a clear photograph of the building they should be sure to describe the architectural characteristics in detail.

IS IT OKAY TO TRESPASS IN ORDER TO SURVEY A PROPERTY AND TAKE PHOTOGRAPHS?

No. Surveyors are required to stay in the public right of way while conducting their fieldwork. Permission from the property owner must be obtained in order to access the property.

WHY CAN'T I USE MY PHONE TO TAKE PHOTOGRAPHS?

While there have been many advances in the technology of smart phone cameras, SHPO is asking surveyors to continue to use a high quality digital camera to take their official photographs. Many phones do not allow users to change the resolution while taking photographs.

WHAT IS MISHPO? HOW DO I GET ACCESS TO THE SYSTEM?

MiSHPO is SHPO's new database and online submission system that will eventually allow consultants, federal agencies, and members of the public to submit their surveys, Section 106 applications, National Register nominations, Tax Credit applications, and other items directly to SHPO online. Any individual will be able to obtain a log-in through the website for the online submission portal. In order to get access to the database to conduct research on known sites, individuals and agencies or companies must purchase a license to gain access to SHPO's data. This manual will be updated once the system is fully operational.

WHAT DOES ELIGIBILITY MEAN? WHO DETERMINES THIS?

Eligibility is the assessment of whether a historic property meets the criteria for listing in the National Register of Historic Places. Persons meeting the professional qualifications as identified in the Code of Federal Regulations 36 CFR Part 61 can make recommendations based on their research of the eligibility of a property or district and SHPO will review the research and agree or disagree with the recommendations.

HOW DO I FUND A SURVEY IN MY COMMUNITY?

Surveys are funded by a variety of sources including private funding, grant funding, and municipal funding. Grant funding is occasionally offered through SHPO's Certified Local Government (CLG) grant program to eligible communities. SHPO uses its federal allocations to fund surveys as well and these are presented as RFPs for consultants. Sometimes a local municipality will utilize their general funds to conduct a survey, usually under the direction of a qualified consultant. Survey is a fundable activity for federal projects in which a survey is required under Section 106 of the National Historic Preservation Act of 1966. At this time SHPO does not offer grant funding to individuals to conduct survey work.

SURVEY PLANNING AND FIELDWORK

Survey is often initiated by a few people and undertaken to address a specific need in a community, but the survey planning process needs to include a much larger group of interested participants. Planning should be a community effort with qualified architectural historians and historians listening and being actively involved with community members to determine what areas are significant to them. Many surveys involve a planning committee that includes any or all of the following:

- Community organizations
- Local historians or representatives of local historical societies, historical commissions, or historic district commissions
- Faculty of local educational institutions with relevant expertise
- Representatives of executive and legislative branches of local government
- A member of the community's planning staff
- Members of the local board of realtors

Surveys should be publicized to the community through different avenues. The surveyor should also notify local law enforcement to explain the nature of the survey activity and make them aware of their presence. Surveyors should also carry identification at all times.

QUALIFICATIONS

Reconnaissance-level surveys must be undertaken by a lead investigator who meets the Secretary of Interior's Professional Qualifications Standards in the Code of Federal Regulations, 36 CRF Part 61. Lead investigators should be trained architectural historians and have experience with research and photography. The investigator should also be well versed in the National Register criteria. For Intensive-level surveys, the researcher or research team should be qualified as architectural historians and historians. An individual may qualify as both.

SHPO maintains a list of qualified consultants and while this list is not exhaustive of the consultants in the state of Michigan, it does provide a list of individuals who have submitted their credentials to the office for review. **Inclusion in this list does not constitute endorsement by SHPO or guarantee that any work product carried out by persons on the list will necessarily meet federal and state requirements.** Before engaging the services of any consultant, it is always advisable to contact references named by the consultant— especially those people for whom a consultant has worked. Inquiring about the nature of the project and the quality and timeliness of the work performed may provide an indication of a consultant's ability to successfully complete your project.

WHAT TO SURVEY

One of the fundamental issues in planning a survey is determining what to include in the project. This determination should be guided by the purpose for which the survey is being carried out, yet tempered by the need to complete the project within a defined budget. Surveys typically fall into two categories:

- Survey everything within the set boundaries, regardless of age, and
- Survey everything more than forty years old within the set boundaries

Surveying everything within the boundaries regardless of age is the most thorough documentation method, but it is also the most expensive and time consuming. This type of survey is appropriate for smaller municipalities or neighborhoods with several hundred properties or fewer. Surveying only what is known to be over forty years old is appropriate for cities and larger municipalities. The forty-year date range is to allow for the National Register's fifty-year age criterion and additional time so the survey is not outdated as soon as it is complete.

The goal of every survey should be to document a full range of types of historically significant properties in the survey area. Historic resources come in many forms—some are not as obvious. The National

Register property types are to be used for surveys in the State of Michigan. For full definitions of these terms according to National Register Bulletins 16A and 24, please see Appendix A, the Architectural History Survey Glossary of Terms.

- Buildings
- Site
- Structure
- Object
- District

Many historic resources such as parks, cemeteries, farms, mill and factory complexes, and residential properties can be complex properties that contain a variety of individual historic features. In an intensive-level survey, the property as a whole and each of its historic features should be surveyed. In a reconnaissance-level survey, it may be appropriate to survey only the entire property and key historic features rather than each and every historic element. Examples of this would include houses and grounds, farms, government complexes, churches, cemeteries, parks, factory and mill complexes, and utilities.

Churches in particular rarely stand alone, and the complexes often include cemeteries, educational buildings such as schools, teachers' residences, parsonages, or rectories, along with additions to the main building. The whole complex may be fronted by ornamental fencing or a gate. All of the various components of such church complexes should be surveyed. Farmstead Survey is discussed further in Appendix B Farmstead Survey Standards.

Questions often arise on whether features such as roadways and walkways; bridges; trees, boulders and other natural features; and mobile home parks or manufactured home developments should be included in the survey.

- For roadways and walkways, only intact, well-preserved examples surfaced with paving brick or other materials not commonly used today, should be included in the survey. Historic examples of public stairways should also be included in the survey.
- Many bridges in Michigan have been previously surveyed in the statewide highway bridge surveys, but some local highway bridges, particularly those no longer in highway use may have been missed. SHPO can provide you with a list of the bridges that have been previously surveyed. Historic culverts, pedestrian bridges, and railroad bridges should be included in the survey.
- Natural features are normally not included in the survey. If they are directly associated with historic events—not merely planted or placed at the site to commemorate them—they should be surveyed. Examples would be witness trees the original surveyors of Michigan used to describe corners of sections or quarter-sections, and trees associated with important persons or events.
- Mobile home and manufactured communities should be included in the survey if they are more than forty years old as they may possess significance in terms of landscape design, social history, and architecture.

CONTRACTING SURVEYS

A few communities will find themselves in the fortunate position of having persons with the requisite background, experience and skills to take on their surveys as volunteer projects, but most will need to contract for some or all of the work. SHPO maintains a list of consultants interested in survey work who meet the basic federal qualifications for historian and/or architectural historian. The list is updated frequently and is available on SHPO's website. This list should not be considered all-inclusive; there may be other consultants in your area who are not listed. It must also be emphasized that inclusion on the list is not a guarantee of high-quality work, and credentials and experience should be reviewed and references consulted. For additional detail regarding the hiring of a consultant and the RFP process please see Appendix C Contracting Surveys.

USING VOLUNTEERS

Some survey projects have been carried out entirely as volunteer projects, and volunteers can certainly assist in specific tasks such as the field survey work and property-specific research. Using volunteers in contracted survey projects, however, should be done with caution and a clear knowledge of the level of commitment of each volunteer. SHPO's experience has been that volunteers are sometimes not sufficiently motivated to carry out assigned tasks without defined deadlines.

ADVISORY BOARD

An advisory board comprising local historians, planners, members of a local historic district commission, and interested citizens can be an asset in a survey. The board may suggest resources for research, people to interview, and collections of information. A valuable role of the board is to be an emissary of good will during the project and an advocate for the survey's use after it is complete.

FIELD WORK

Field work is one of the most important steps in the survey process. Field work should:

- Record locational and descriptive data on each property
- Photograph properties and context views
- Map the property locations

One of the important steps before beginning fieldwork is the preparation of maps. Maps should be obtained from the local community to create base maps that will be used in the field and then in the preparation of the final map. The more detailed the maps, the more useful they will be in precisely locating the surveyed resources and in assisting users of the survey materials in their comprehension of the survey area's historic resources. Maps should show all streets and current property lines and/or building outlines.

More information on mapping in the MiSHPO system will be provided later in this manual.

RECORDING DATA IN THE FIELD

The collection of field survey data is one of the most important steps in the survey process. Field survey will provide locational and descriptive information—and perhaps some historical background information obtained by informants—about each property, which will ultimately form part of the record for the property. Prior to beginning field work, surveyors should review the list of required fields or data categories and instructions for the MiSHPO system. Surveyors should also include as much information as possible in each of the fields. Some examples of required fields include:

- Address (number, street direction and street name)
- City/village or township
- County
- Survey date and surveyor
- Historic name and current name
- Current building materials
- Additions, removals, and condition of the property

Many surveyors use paper survey forms and enter the data into the system at a later date. Many surveyors also create their own paper forms for use in the field. The SHPO Survey and Information Coordinator or the National Register Coordinator are available to review survey forms prior to the

commencement of field work. See Appendix D for a sample field form that can be customized and reproduced.

At this time, the use of survey applications for smart phones is not available for use with the MiSHPO program, but SHPO hopes to develop one in the coming years so surveyors will be able to utilize the technology in the field.

PHOTOGRAPHIC DOCUMENTATION

Every property included in the survey, including each building and other surveyed feature in a complex property or district, requires a minimum of one high quality photograph to show as much of the property as possible. Each surveyor is required to use a digital Single Lens Reflex (SLR) camera with a minimum capture size of eight mega-pixels. Images must be shot at the highest photo resolution possible.

Images must be delivered as an unaltered JPEG image on disk or thumb drive. Each image must be a minimum of 2000 pixels and 3000 pixels. Please consult with SHPO staff regarding file naming conventions for survey photos.

Survey photography is documentary. Good photographs can be taken if the photographer keeps several things in mind beyond the normal photographic considerations. These include composition, clarity, lighting quality and direction, and perspective distortion. Prior to beginning photography, a plan should be made based on the direction the building faces relative to sunlight, timing of possible obstructions (holiday decorations, leaves, vehicles, etc.), daylight, and weather.

CLARITY

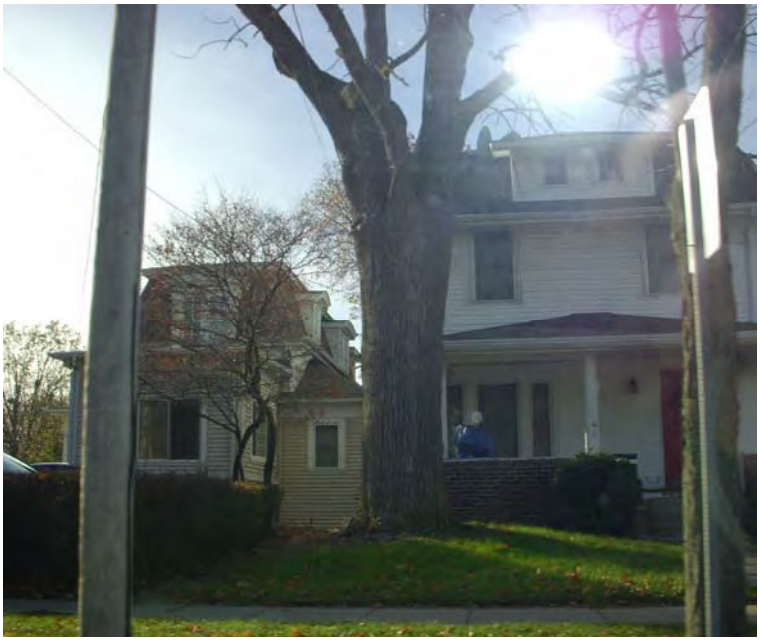
The major cause of unclear photographs is camera movement. The best way to avoid this is to place the camera on a firm support or tripod when the photograph is being taken. If a tripod is unavailable, using a faster shutter speed and gently squeezing the shutter button can enhance image clarity.

COMPOSITION

Generally, a ¾-view of a building is preferred, to show as much building detail as possible in a single view. Since a record is produced for each property, do not include the adjacent buildings in the inventory photographs. If necessary, more than one photograph should be taken to document large or complicated buildings.

LIGHTING QUALITY AND DIRECTION

A building is modeled and described by the sunlight, and the relationship of the sun to the property varies from case to case. A photo of a rusticated building, for example might be enhanced by sun using direct light to bring out the texture. A building with a broad overhang is sometimes best photographed in hazy sun because deep shadows can obliterate details. It is difficult, therefore, to generalize, except to say that the photographer should study the subject and make a determination based on a building's inherent characteristics.



Be careful about backlighting, or placing the sun directly behind the camera, because such flat lighting can obscure the shadow lines that give a building character and depth.

PERSPECTIVE DISTORTION

An otherwise well-thought-out photograph can be ruined by perspective distortion. The only way to get rid of this distortion completely is to have the film plane of the camera exactly vertical when taking the photograph. Tipping the camera up to capture the top of the building is the most common perspective distortion, this makes the building appear to be falling over backwards. The best way to limit the impact of this distortion is by using a perspective-control (PC) lens. Those without access to such equipment, however, should follow a few simple tips. The easiest solution is to back up far enough from the subject to include the entire building without tilting the camera upward. This can be accomplished by either moving away from the subject or by changing the camera to a wide-angle setting. Surveyors should use caution when using a wide-angle lens as this can exaggerate any tilting of the camera.

A telephoto lens that tends to flatten buildings can be used to reduce the impact of the perspective distortion. Users of a telephoto lens should be aware that the lens can also exaggerate camera motion, so a tripod is recommended.

Surveyors can also stand on a rise, truck, ladder or other equipment to elevate themselves and reduce the perspective distortion.

More information on photography is available in National Register Bulletin 23 *How to Improve the Quality of Photos for National Register Nominations*.

Other photography tips include the following:

- Avoid signs, cars, people, trees, and poles in the foreground as much as possible
- Lens filters and shields should be used to minimize glare
- Use imagination in finding the position that will allow the best view of the property

DESCRIBING HISTORIC PROPERTIES

Architecture should be described using appropriate terminology for architectural styles, building forms, and other characteristics. Surveyors should make use of architectural style guides, studies of specific building types, and other source material that provide background information about the architecture they are surveying. The following resources should prove useful for nearly every survey:

- Architectural Dictionaries and Terminology Guides:
  - Phillips, Steven J. *Old-House Dictionary*. NY: John Wiley & Sons, Inc., 1994.
  - Burden, Ernest. *Illustrated Dictionary of Architecture*. Third Edition. NY: McGraw-Hill, 2012.
  - Roth, Leland M. *American Architecture: A History*. Second Edition. CO: Westview Press, 2016.
- Houses:
  - McLennan, Marshall. "Common House Types in Southern Michigan." In Michigan Folklife Reader, edited by C. Kurt Dewhurst and Yvonne R. Lockwood, 15-45. East Lansing: Michigan State University Press, 1987.
  - McAlester, Virginia and Lee McAlester. *A Field Guide to American Houses (Revised).* NY: Alfred Knopf, 2015.
- Farms and Agricultural Buildings:
  - Michigan Agricultural Experiment Station bulletins and Michigan Cooperative Extension

Service bulletins, found at the Michigan State University Library, contain useful background information on farm and building layouts and design.

- *The Agricultural Landscape of Michigan: An Historic Context for the Theme of Agriculture*. Lansing, MI: Michigan State University for Michigan Department of Transportation, 2004. On file at SHPO and MDOT.
- Dandekar, Hemalata C. *Michigan Family Farms & Farm Buildings: Landscapes of the Heart & Mind*. Ann Arbor: The University of Michigan Press, 2010.
- Noble, Allen G. *Wood, Brick & Stone: The North American Settlement Landscape.* 2 vols. Amherst, Ma: University of Massachusetts Press, 1984. Volume 2 deals with barns and farm structures.
- Noble, Allen G., and Hubert G. H. Wilhelm, eds. *Barns of the Midwest*. Athens, OH: Ohio University Press, 1995.
- Visser, Thomas Durant. *Field Guide to New England Barns and Farm Buildings*. Hanover, NH: University Press of New England, 1997.

- Mid-Century Modern Resources
  - APT Building Technology Heritage Library. https://archive.org/details/buildingtechnologyheritagelibrary. Includes house plan books for postwar housing companies.
  - *Historic Residential Suburbs. Guidelines for Evaluation and Documentation for the National Register of Historic Places.* U.S. Department of the Interior. National Park Service. Washington, DC. 2012.
  - Jester, Thomas C. *Twentieth-Century Building Materials: History and Conservation*. Los Angeles: Getty Conservation Institute. 2014.
  - *A Model for Identifying and Evaluating the Historic Significance of Post-World War II Housing*. National Cooperative Highway Research Program Report 723. Transportation Research Board Washington, DC. 2012.
  - *The Ranch House in Georgia. Guidelines for Evaluation.* Stone Mountain, Georgia: New South Associates.
  - Statewide Search for Subdivision Plats. www.dleg.mi.us/platmaps/sr_subs.asp. Michigan Department of Licensing and Regulatory Affairs (LARA).
- Schools
  - Michigan State Historic Preservation Office. *An Honor and an Ornament: Public School Buildings in Michigan*. Lansing, Michigan: Department of History, Arts and Libraries, 2003.
  - Michigan Superintendent of Public Instruction. Superintendent of Public Instruction Annual Reports. Lansing, MI: State of Michigan Superintendent of Public Instruction. The annual reports of 1859, 1864, 1869, 1893, 1913-1914, 1915-1916, and 1916-1917 contain illustrated material on school building design and furnishings, including standard plans.
- Commercial Architecture
  - Longstreth, Richard. *The Buildings of Main Street: A Guide to American Commercial Architecture.* Walnut Creek, CA: AltaMira Press, 2000.
- Industrial Architecture

For specific questions concerning architectural terminology, contact the Survey and Designation staff at SHPO.

HISTORICAL RESEARCH

All surveys should include a historical research component. Historical research in survey provides the framework for evaluating the historic significance of the surveyed properties and their eligibility for inclusion in the National Register of Historic Places.

The primary difference between reconnaissance-level survey and intensive-level survey is that intensive-level survey includes in-depth historical research on each of the surveyed properties. Reconnaissance-level survey only records property-specific information from readily available sources. Both levels of survey should include research in two areas: 1) the general history of the survey area or community and 2) study of historical themes applicable to the survey area. Intensive-level survey will include the individual property history information as well.

The survey report must include a summary history of the area that introduces the important historic themes and places them in a broader context. The history should be written as a narrative rather than in timeline format. It should include key dates in the area's chronology and introduce the area's early settlement history, driving forces behind its growth and economy (including significant people or ethnic groups) and other developmental factors. An example for Port Hope (see below), taken from the Port Hope multiple property nomination for the National Register, introduces each of the significant historic themes represented by properties included in the nomination: lumbering, forest fires of 1881 and relief efforts, agriculture, transportation, ethnic history, and architecture.

Thematic narratives should be identified through consultation with National Register Bulletin 15, "How to Apply the National Register Criteria for Evaluation" (page 8), which defines a theme as "a means of organizing properties into coherent patterns based on elements such as environment, social/ ethnic groups, transportation networks, technology, or political developments that have influenced the development of an area during one or more periods of prehistory or history."

ARCHITECTURAL NARRATIVE

For most survey projects, architecture will prove a relevant theme, and an architectural narrative will be necessary. Architectural narratives too often tend to be generic discussions focusing on style that provide little detail about the specific survey area. This should be avoided! It may be worthwhile for the person preparing the architectural narrative to begin with a fresh review of architecture while in the field. Working from only the survey photos months after the completion of the field survey may hinder insightful analysis of the architecture.

The purpose of the architectural narrative is to place the survey area's architecture in the broader context of the community and region in which it is located. The architectural narrative should discuss the architecture in terms of property types. Property types should be defined using the list in Appendix E.

The architectural narrative should discuss all property types within the broad categories (residential, commercial, or agricultural) for which a substantial number of properties are present. For example, for rural survey areas containing numerous farms, the broad range of agricultural building and structure types present should be discussed and analyzed. For older, in-town neighborhoods containing many old stable/carriage house buildings, the architectural narrative should include some discussion of this building type. Conversely, property types represented in the survey area by only one or a very small number of properties—typically churches, schools, and other institutional resources—need not be included in the architectural narrative. For the few institutional properties present in most survey areas, any needed architectural analysis can be presented within the narratives for the themes with which the properties are associated, such as religion or education.

Just as for the entire survey report, an important purpose of the architectural narrative is to educate public officials, planners, property owners, and the general public about what is interesting and significant from an architectural standpoint about the survey area's properties. A relatively small number of high-style properties in the survey area certainly merit discussion and analysis, but the narrative should focus on

the common property types and forms generally represented by the vast majority of surveyed properties whose significance will not be obvious to the report's readers.

The narrative should be organized by broad property type, such as residential and commercial. The discussions of property types should be arranged in the overview in the approximate order of their predominance. In most survey areas, residential properties will form by far the greatest proportion of the surveyed resources; in such cases, the residential section should come first in the architectural narrative.

In the discussion of each property type, discussion and analysis of the issues of form and massing should almost always precede any discussion of style. For example, in a section of an architectural narrative that discusses single-family houses within a broad category of domestic (i.e. residential) architecture, the houses should be discussed in terms of the specific house forms present, such as bungalow or upright-and-wing, before they are discussed in terms of their architectural style. Building forms characteristic of the survey area and broader community, such as a certain house form prevalent in a survey area, but less common elsewhere, should be identified. Any locally distinct varieties of standard architectural styles and the common use of distinctive decorative elements in the local architecture, such as a polychromatic brickwork found in many houses in the Dutch settlement area of West Michigan, should be noted and discussed.

Examples of pattern-book, pre-cut, and manufactured architecture should be discussed, if possible, as part of the architectural narrative. While originals of old pattern and plan books and catalogs are hard to come by, many of these books have been reprinted by a variety of publishers, and more are being done every year. Dover Publications, Inc., the publisher of by far the greatest number of reprints, is the architectural historian's friend, having reprinted dozens of old plan and pattern books since the 1960s, with most of them still in print in inexpensive paper editions. These pattern books—especially those by the Aladdin Company and Sears, Roebuck and Company—will be useful for survey in Michigan.

The narrative should provide information about architects, engineers, artisans, craftspeople, and contractors who worked in the survey area. Biographical data, such as birthplace and birth and death dates, educational background, firm affiliations and dates, and important commissions are important pieces of information that should be sought and included in the narrative. Newspaper obituary notices are an important source of information. In addition, the following can be useful sources of information on architects and engineers:

- *American Institute of Architects Historical Directory of AmericanArchitects*
- *Avery Obituary Index of Architects.* Microform/Columbia University. Boston, MA: G.K. Hall, 1984.
- Downs, Winfield Scott, ed. *Who's Who in Engineering. A Biographical Dictionary of the Engineering Profession.* New York: Lewis Historical Publishing Co., Inc. (Editor, title and publisher vary between editions). Eight editions were published between 1922 and 1959.
- Koyl, George S., ed. *American Architects Directory*. New York: R. R. Bowker Co. Editions were issued in 1956 and 1962.
- Withey, Henry F., and Elsie Rathburn Withey. Biographical Dictionary of American Architects (Deceased). Los Angeles: New Age Publishing Co., 1956.

RECONNAISSANCE-LEVEL SURVEY

The level of research for a reconnaissance-level survey will be limited to those documents and resources that are easily accessible including old county and fire insurance maps and published histories, as well as information such as historic name and date, gleaned from inspections of the property. The recording of specific information from directories, tax assessors' records, and other more detailed sources is generally not a part of a reconnaissance survey. For some of the properties, no historical information will be located.

INTENSIVE-LEVEL PROPERTIES

For properties surveyed at the intensive-level at least a basic level of information should be gathered for each of the properties forty-or-more-years-old, with more in-depth research performed on those that appear to possess more than typical historical or architectural significance. The surveyor must provide a basic, standard level of historical documentation for all of the surveyed properties and help determine which of them possess significance according to the National Register criteria.

The amount of time spent on research for a given property in an intensive-level survey should correspond to the property's apparent historic significance. Property-specific research can be the most time-consuming aspect of a survey project, but it is the most important. Surveyors should have realistic expectations about what information is available, so that research efforts can be appropriately directed. Sometimes finding basic information for a property, such as the precise date of construction and an architect or builder, will be impossible.

SOURCES OF INFORMATION FOR HISTORICAL RESEARCH

The sources of information that will be used for general history, thematic, and property-specific research will vary with the nature and location of resources, but the following will generally be useful tools.

- Published and unpublished histories
- County maps and atlases, plat books, and fire insurance maps
- City and county directories
- State gazetteers and business directories
- Tax assessors' records
- Tax records
- Building permit records
- Local historians and knowledgeable informants, including long-term property owners
- Federal census records
- State census records
- Rural property inventories
- Vertical and newspaper clippings files
- Photograph collections
- Birdseye views
- Biographical albums and records
- Newspapers
- Property abstracts
- Public land records
- Federal land patent records

While secondary sources can be useful to begin your research and uncover potential primary sources, they should be used with caution and primary sources should be used as the main documentation whenever possible.

SUMMARY HISTORY FOR PORT HOPE

EXAMPLE

Port Hope began in 1858 with a sawmill and dock constructed by William R. Stafford, a partner in a firm established to log the area and market its products to Cleveland. Lumber continued to be the area's chief industry until forest fires in 1871 and 1881 destroyed most of the remaining timber. The 1881 fires, coming after decades of logging had left mountains of timber debris in their wake, not only destroyed most of the remaining forests in the area, but also cleared much of the debris left from logging activities, opening the Port Hope area and much of the Thumb to farming far more than the lumber industry itself. The land was fertile. As a result, in the 1880s and 1890s agriculture became the major livelihood of Port Hope's residents. Many early settlers in Port Hope in the 1860s and 1870s were Germans and in the late nineteenth century the Germans became Port Hope's largest ethnic group. Cheap water transportation on the lakes made possible the community's economic growth in the nineteenth century. Lumber and, later, agricultural products were shipped to market exclusively by boat prior to the construction of a railroad line to the town. The opening of a rail link to the existing line at Harbor Beach in 1903 took place at the same time that commerce on the lakes was in decline because of competition from the ever-growing railroad network. The railroad line gave Port Hope a greater market for its agricultural products and encouraged further development of agriculture in the area. Port Hope's architecture in the nineteenth and early twentieth centuries reflected the development of the town and the contemporary architectural tastes of the nation at large and of Michigan's Thumb region.

LUMBER INDUSTRY THEMATIC NARRATIVE FOR PORT HOPE

EXAMPLE

Commercial logging in Michigan began in the 1830s, 40s, and 50s with the development of improved sawmilling technology and the introduction of steam-powered sawmills. Extensive logging began along the east shore of Lake Michigan and the west shore of Lake Huron in the Lower Peninsula and gradually worked its way inland along the major waterways. The sawmills were located at the mouths of the streams and the logs driven downstream to them during the spring high waters. Chicago was the first the principal destination of timber cut along Michigan's west shore, while the mills on the Lake Huron side of the state served Detroit, Toledo, Cleveland, and Buffalo for the most part. In 1860 there were nearly one thousand sawmills operating in Michigan producing in that year about 800 million board feet of lumber, principally white pine. The fine quality of the wood and the phenomenal growth of Michigan's and the Midwest's population in the years after 1860 led to rapidly expanding lumber production in Michigan. Production statewide reached a maximum of 4,292,000,000 board feet in 1888. Production began to decline thereafter because of the depletion of timber lands; however, Michigan continued to be the leading producer of lumber in the nation in 1900.

Commercial logging along the west shore of Lake Huron began in the 1830s and was well underway at Port Huron, Saginaw, Bay City, and other places by the late 1840s. Port Huron reached its high point of lumber production—56 million board feet—in 1873. The Saginaw Valley reached its high point of production of more than one billion board feet in 1882. More northerly points such as Alpena and Cheboygan reached their peak production in the late 1880s and early 1890s. Much of the production from the east shore mill towns was sent to market in ships and barges, and Bay City and Saginaw in particular became large shipbuilding centers in the late nineteenth century.

Eastern investors, a number from Maine and New Hampshire, played an important role in the Michigan lumber boom beginning as early as the 1840s, if not before. These investors witnessed the gradual depletion of the northern New England pine woods in the mid-nineteenth century and the consequent rise in value of the remaining timber lands. They recognized the opportunities for profit from Michigan timber lands, which could still often be bought at bargain prices from Uncle Sam and the lumber inexpensively shipped by water to an ever-growing market. Single investors often bought thousands of acres of land, logged them off over many years, and then resold as much land as possible while developing some themselves for agricultural purposes.

Huron County, at the tip of the Thumb between Lake Huron and Saginaw Bay, was established as a county in 1859. The first sawmills—small, water-powered affairs—were established in 1838 and 1839. John Hopson put up the first steam sawmill in 1850 at Rock Falls south of Harbor Beach. Lumber and shingle manufacturing quickly became the county's chief industries. The principal woods were pine, hemlock, cedar, basswood, beech, maple, birch, and ash. A series of forest fires burned over much of the county in October 1871, at the same time that the Chicago Fire raged. Nevertheless, in 1874 the county produced 36 million board feet of lumber. In 1876 several planks cut at Verona Mills in the county were displayed at the Centennial Exposition in Philadelphia. The planks were sixteen feet long, five feet two inches wide, four inches thick, and without knots or other flaws. In September 1881, however, another series of disastrous fires burned over the bulk of Huron and much of several other counties and put an end to large scale logging in the county. Small scale operations continued for a few more years here and there.

In Port Hope William R. Stafford was a pioneer lumberman. Stafford (1829-1916) came to Michigan from Bath, New Hampshire, in 1849 and settled in Lexington, on the Lake Huron shore between Port Huron and Huron County. In 1852, Stafford became a partner in a mercantile business that apparently involved lumber. The business was reorganized in 1854 with Clark Haywood, another New Hampshire native and a former employee of Stafford's, as his partner.

In 1851, Stafford, Reuben B. Dimond, William Southard, and Josiah F. Wilson, all (with probably the exception of Dimond) New Hampshire natives who were personal friends and business associates, made a purchase of timber lands in the area near what became Port Hope. In 1857 or 1858, Stafford, Haywood, and a third New Hampshire native, former U.S. senator B. W. Jenness, then a resident of Cleveland, formed a partnership to exploit the timber resources of the Port Hope area. Stafford had charge of the sawmill the partners built in 1858 at what became the settlement of Port Hope. The mill produced lumber,

lath, and shingles. Jenness ran a lumberyard in Cleveland that the Port Hope mill supplied. During some years prior to the 1871 fires the mill produced 7 million board feet of lumber. The 1871 fire destroyed the mill, dock, and lumber on hand, a loss of $100,000 to Stafford & Haywood (Jenness had withdrawn in 1868). Stafford & Haywood rebuilt the mill and dock in 1872. As of 1874 they produced 1.4 million board feet out of the 36 million produced in the county. At least four operations in the county were larger. The 1881 fire burned the mill and dock again, a $40,000 loss, and, in 1884, Haywood also withdrew from the firm, leaving Stafford as sole owner. Stafford built a third, smaller sawmill and planing mill and sash and door factory to supply primarily local needs.

In 1880, R. C. Ogilvie built a second sawmill and dock at a cost of eight-thousand dollars. The mill and dock also burned in 1881. Ogilvie rebuilt in 1993, but the mill apparently closed for the lack of timber by about 1889. Stafford's sawmill is listed in the Michigan State Gazetteer and Business Directory as late as the 1893 edition, and probably closed in the early 1890s. Perhaps some lumber and other wood building products were shipped to Cleveland until the very end of local sawmilling operations. Mrs. C. J. Bisbee in her 1915 historical sketch of Port Hope states that "The mill operated until every bit of virgin timber was nailed into Ohio houses."

A by-product of logging in Michigan was salt manufacturing. What is known to geologists as the Michigan Basin, which includes the Lower Peninsula, is one of the greatest areas of halite concentration in the world. Subsurface deposits of rock salt and brine occur in many places. In 1859 the Michigan legislature, hoping to encourage salt production, authorized a bounty of ten cents per bushel produced. This bounty was soon repealed, but not before it had done its work in generating real interest in salt manufacturing. Michigan soon became the nation's leading salt producer, and by 1884 was producing half of the nation's salt.

Salt production in Huron County and elsewhere in Michigan was encouraged by the plentiful supply of wood. Wood fueled the engines that pumped the brine from which salt was obtained up to the surface and powered the furnaces that evaporated water from the great pans or vats of brine. Cheap fuel made Michigan salt the most inexpensive in the nation. In Huron County salt manufacturing began in 1863 in Port Austin and continued until about 1890. In 1884 the county had eleven salt-manufacturing operations, several of them using more than one well. The decline coincided not with the depletion of the brine deposits, but with the destruction of the forests that provided the cheap fuel.

In Port Hope the first salt-manufacturing enterprise, the Port Hope Salt Company (in which W. R. Stafford was the principal owner) was established in 1874. Its plant appears to have been typical of the Huron County salt "blocks." The first year the company produced 16,000 barrels of salt at 280 pounds per barrel. In 1884 the company used 10,000 cords of wood to produce 60,000 barrels. It had a well 800 feet deep (Huron County wells ranged from 600 to nearly 2,000 feet in depth) and four and one half inches in diameter. The brine was pumped to the surface into five evaporating "pans" and the brine settled to the bottom. So-called "bitter water" at the top was drained off. Furnaces provided the chief means of evaporation. A force of twenty coopers produced the needed barrels. Much of the salt produced went for dairy purposes, but the company also shipped much of its product to the mining regions of Montana. The Port Hope Salt Company closed in 1890.

Robert G. Ogilvie established a second salt-manufacturing concern in Port Hope in 1883. His operation had its own sawmill and barrel factory and produced 150 barrels of salt daily in 1884. Ogilvie's operation apparently closed by 1890.

The remains of the Port Hope Salt Company plant were dismantled in 1913-14, but the site has not been developed and some remains are still present. At the site of the Ogilvie salt block, some development has taken place and no remains are visible. No archaeological testing of either site has been done.

EVALUATION AND MAKING ELIGIBILITY RECOMMENDATIONS

Evaluation of the historic significance of the surveyed properties is the very heart of the survey project since the properties evaluated as historically significant are the ones to which future historic preservation planning efforts will be geared and the rest of the properties will likely be excluded from future preservation planning. Evaluation criteria for surveys of any kind should use the National Register of Historic Places Criteria for Evaluation.

CRITERIA: The quality of significance in American history, architecture, archaeology, engineering, and culture is present in districts, sites, buildings, structures and objects that possess integrity of location, design, setting, materials, workmanship, feeling, and association, and:

A. That are associated with events that have made a significant contribution to the broad patterns of our history; or
B. That are associated with the lives of persons significant to our past; or
C. That embody the distinctive characteristics of a type, period, or method of construction, or that represent the work of a master, or that possess high artistic values, or that represent a significant and distinguishable entity whose components may lack individual distinction; or
D. That have yielded, or may be likely to yield, information important in history or prehistory.

CRITERIA CONSIDERATIONS: Ordinarily cemeteries, birthplaces, or graves of historical figures, properties owned by religious institutions or used for religious purposes, structures that have been moved from their original locations, reconstructed historic buildings, properties primarily commemorative in nature, and properties that have achieved significance within the past 50 years shall not be considered eligible for the National Register. However, such properties will qualify if they are integral parts of districts that do meet the criteria or if they fall within the following categories:

A. A religious property deriving primary significance from architectural or artistic distinction or historical importance; or
B. A building or structure removed from its original location but which is significant primarily or architectural value, or which is the surviving structure most importantly associated with a historic person or event; or
C. A birthplace or grave of a historical figure of outstanding importance if there is no appropriate site or building directly associated with his productive life; or
D. A cemetery which derives its primary significance from graves of persons or transcendent importance, from age, from distinctive design features, or from associations with historic events; or
E. A reconstructed building when accurately executed in a suitable environment and presented in a dignified manner as part of a restoration master plan, and when no other building or structure with the same association has survived; or
F. A property primarily commemorative in intent if design, age, tradition, or symbolic value has invested it with its own exceptional significance; or
G. A property achieving significance within the past 50 years if it has exceptional importance.

EVALUATION PROCESS

Evaluating historic resources should involve assessing historic properties from three perspectives:

- Historic context
- Historic significance
- Historic integrity

HISTORIC CONTEXT

Historic resources must be understood within the framework of the historic themes with which they are associated and the place and time in which they occurred. The theme, geographic parameters, and temporal definition provide the context for understanding a property, for example, popular music (theme) in Detroit (place) from 1920 to 1975 (time frame). Evaluations need to include:

- Comparison with properties that are similar in terms of function, form or style
- Relationship to a historic event
- Comparison with other properties associated with the same historic theme(s) and in the same geographic area and time frame

The geographic area that forms one of the bases for evaluation may need to be larger than the survey area to provide an adequate context for evaluation. In general, evaluations should be made, at a minimum, within the context of the entire community.

The historical significance of an above-ground property refers to its importance in the history, architecture, or culture of the local area, state, or nation. Significance is defined in terms of the four National Register criteria: historic events, important people, distinctive physical characteristics, and information potential.

Historical integrity of a property refers to the extent that the physical components have survived from the historic period—in other words, how much the property reflects its historic appearance. The National Register criteria defines seven qualities of integrity that properties must meet: location, design, setting, materials, workmanship, feeling, and association.

If the history of a property is deemed important within one or more historic themes and if the property possesses a high degree of integrity, it is generally considered eligible for listing in the National Register of Historic Places. The surveyor makes recommendations on the eligibility of resources, which are then reviewed by SHPO staff, who make the final determination.

In addition to these instructions, survey personnel should review the *Secretary of the Interior's Standards for Evaluation*; *National Register Bulletin 15: How to Apply the National Register Criteria for Evaluation*; and other National Register bulletins, as appropriate to the surveyed resources.

Evaluations should be done through the identification of the applicable themes and the related properties in the surveyed area through the creation of lists for inclusion in the survey report. The list for each theme should include not just properties that clearly possess historic significance but also a more representative sampling of all of the types of properties that reflect the theme. When placing these lists in the report, the properties should be organized by a broad property type category (such as Commercial or Domestic). Districts identified in the survey and properties such as farms, industrial complexes, parks, and cemeteries should each be listed and evaluated as whole complexes. Components should not be listed and evaluated separately unless the entire district or complex property turns out not to meet the criteria. Some properties will relate to more than one theme; these should be listed under all appropriate themes. The property list for architecture should be organized by styles, building forms, and other aspects of the survey area's architecture defined in the narrative as significant.

Using the National Register criteria, standards should be developed for evaluating properties associated with the survey area's defined historic themes. For each theme, define the following:

- Property types that are important in illustrating the theme
- How the National Register criteria apply to each property type on the basis of the important events, people, and patterns, etc., developed in the narratives (In some cases several property types may be grouped together.)
- The level of physical integrity a property must possess to be eligible for listing as an example of the property type

The following are examples of specific criteria established for individual property types or groupings of property types within a theme:

- The criteria under the theme of commerce might define a commercial building as eligible for the National Register if it housed a leading commercial enterprise by virtue of its size and role in the community (a department store in a large community or a general store in a small community, for example) or if it housed a specific business or business use for a long period of time (a hardware or clothing store, or a succession of shoe stores or ice cream parlors, that remained in business at the same location, for example).
- The criteria under the commerce theme might define a house as eligible for the National Register if it is associated with a pioneer merchant or businessperson who owned an important business or a business that remained in operation for a long time.

Criteria should be tailored to the survey area's historic themes and to the surveyed properties and property types. Avoid using a standard, "canned" criteria that applies to all themes.

EVALUATION AND RECONNAISSANCE-LEVEL SURVEY

Every reconnaissance-level survey should include at least a measure of evaluation based on the criteria and a recommendation of eligibility for the properties in the survey area. In order for a reconnaissance-level survey to be useful in future planning efforts, the surveyor should use available information, including basic historic information and the level of architectural integrity. For those resources with widely available histories, the surveyor should undertake the evaluation process in the manner described above utilizing all four National Register criteria. For those without a well-documented history, the survey report should include an eligibility recommendation for National Register criterion C: architecture. Reconnaissance-level surveys should be considered locally as the first step in a two-step process; however, funding often limits the ability of a community to complete the second step— intensive-level survey—in a timely manner.

EVALUATION AND INTENSIVE-LEVEL SURVEY

Evaluation of resources for an intensive-level survey should be undertaken utilizing all four National Register Criteria.

IDENTIFYING AND DOCUMENTING POTENTIAL HISTORIC DISTRICTS

One purpose of survey is to identify and document any potential historic districts located within a survey area. According to National Register Bulletin 15, "A district possesses a significant concentration, linkage, or continuity of sites, buildings, structures, or objects united historically or aesthetically by plan or physical development. . . . A district derives its importance from being a unified entity even though it is often composed of a wide variety of resources. The identity of a district results from the interrelationship of its resources, which can convey a visual sense of the overall historic environment or be an arrangement of historically or functionally related properties."

Historic districts can encompass business districts, residential neighborhoods, rural villages or agricultural districts. These areas must possess significance under one or more of the National Register criteria and retain an adequate degree of architectural integrity. The boundaries of the potential historic district must include the full extent of the historic resources related to the applicable historic themes and time frames while excluding adjacent areas whose properties bear no strong relationship to them.

APPLYING THE CRITERIA

A CASE STUDY ON THE HOME OF A SETTLER FROM NEW YORK STATE

Robert O. Christensen

A building that was the Michigan home of a pioneer settler from New York State should be reviewed in terms of the broad pattern of migration to the area from upstate New York and the settler's importance as a reflection of that migration and as a member of the community, and conceivably, the importance of the building itself in reflecting the architectural tastes of the date in that area.

In reviewing eligibility, the history of the area should be considered. For the settler's house, it is important to know whether or not the migration from upstate New York to this area was a common pattern. If it was, the house can be viewed as possessing some significance through the connection with this broad pattern of local history. It is also important to know whether the settler played a significant role in local history. Was he or she a businessperson who established a general store that served the community for a long period of time, for example, or a farmer who played a key role in introducing a new and ultimately important crop? In other words, was the subject someone who made a definable contribution to local history?

Architectural significance also may be a factor in the evaluation. Does this upstate New York settler's house fall into a broad architectural pattern in illustrating the use of building forms or materials characteristic of upstate New York that were used by other early settlers who came from that area? Does the building exemplify commonly used traditional house forms or high-style design of its period, or is it an important example of its designer's work—whether the designer was a fashionable architect of national reputation or a local carpenter-builder?

Once some conclusions concerning how the building fits into the patterns of local history have been reached, an attempt should then be made to determine whether the house is of sufficient importance within these historical patterns to merit designation. For example, perhaps the settler was but one of a great number of such people who settled in the same general area and many of the houses these settlers built have survived. The evaluation of this particular building's importance in representing the theme of the eastern migration to the area might be much less than it would be if only a few of the early settlers' homes had survived, say in an urban area.

Here, the issue of physical integrity becomes important. If fifty houses that relate to the settlement of the area of New Yorkers survive, certainly some of them—all other things being equal—illustrate better than others what it was like for these New Yorkers to establish their lives in Michigan in the early days. Those that retain enough of their historic appearance and character to provide a clear illustration are of greater importance than those that have lost this ability.

Synthetic siding, major renovations that result in the loss of original materials such as trim, and moving from the original site reduce the ability of a building to convey its significant history. Most buildings do not remain in pristine form, and many have been moved. How much the alterations have reduced the overall ability of the building to illustrate the history must be evaluated. In effect, the standards for physical integrity for properties possessing historical significance only mildly related to the architecture differ somewhat from those of properties whose significance is primarily architectural.

The New York settler's house loses a strong measure of significance if it is moved off the property on which the pioneers actually settled. The house loses some measure of significance if synthetic siding is installed or other changes are made, but may retain sufficient integrity to be eligible if the changes made are reversible ones that do not change the fundamental character of the property.

On the other hand, a building that is viewed as eligible primarily because of its architectural value in illustrating high style or vernacular tastes of its time period may not be viewed as losing integrity by being moved (as long as the new setting is appropriate), but may be viewed as losing a substantial amount of integrity by being sided or changed in other ways that reduce the building's ability to illustrate the historic architectural finishes and materials.

SURVEY PRODUCTS AND REPORT

A final survey report is required for all survey projects. This report must be uploaded to the MiSHPO "My Applications" tab. The survey report should provide information on the purpose, parameters, methodology, limitations, findings, background, historical context, and descriptions on the findings. SHPO requires that report authors adhere to the most recent edition of the *Chicago Manual of Style and the* *Michigan State Historic Preservation Office Style Guide*.

SURVEY REPORT COMPONENTS: SECTION ONE

- COVER OR TITLE PAGE: Include the name of the survey, municipal unit(s) and counties, sponsoring agency, completion date of the final report, names and location of the person or firm responsible for carrying out the survey, and names of the report author and primary project personnel, if different.
- ACKNOWLEDGMENTS/FUNDING CREDIT: Most projects are funded by federal, state, or local funding and the source of funding should be acknowledged in the report. For project funded through the Historic Preservation Fund, the following acknowledgment of federal assistance is required behind the title page and before the executive summary:

The activity that is the subject of this project has been financed in part with Federal funds from the National Park Service, U.S. Department of the Interior, through the Michigan State Housing Development Authority. However, the contents and opinions herein do not necessarily reflect the views or policies of the Department of the Interior or the Michigan State Housing Development Authority, nor does the mention of trade names or commercial products herein constitute endorsement or recommendation by the Department of the Interior or the Michigan State Housing Development Authority.

This program receives Federal financial assistance for identification and protection of historic properties. Under Title VI of the Civil Rights Acts of 1964, Section 504 of the Rehabilitation Act of 1973, and the Age Discrimination Act of 1975, as amended, the U.S. Department of the Interior prohibits discrimination on the basis of race, color, national origin, disability, or age in its federally assisted programs. Michigan law prohibits discrimination on the basis of religion, race, color, national origin, age, sex, marital status, or disability. If you believe you have been discriminated against in any program, activity, or facility as described above, or if you desire further information, please write to:

Chief, Office of Equal Opportunity Programs
United States Department of the Interior
National Park Service
1849 C Street, NW
Washington, DC 20240

- EXECUTIVE SUMMARY: Briefly describe the scope of the survey project, its purpose and goals, and the results in terms of the survey products, evaluations of eligibility for the National Register of Historic Places, and recommendations for local districting and other actions. Provide a summary of National Register eligibility recommendations and any other recommendations for action from the Evaluation Results and the Planning Needs and Recommendations sections. The executive summary should direct the reader to the appropriate sections of the report (include page numbers) where more detailed information can be found. This information will be copied into the MiSHPO survey submission as the abstract. **As part of the executive summary, the following information is required for all surveys submitted to SHPO.**
    - Number of properties surveyed at the reconnaissance level and at the intensive level: break this down by municipal unit if survey work took place in more than one and break it down by area if survey activities took place in more than one survey area.
    - Number of acres and hectares surveyed (SHPO requires this information as it must be reported to the National Park Service).

- TABLE OF CONTENTS
- CREDITS AND CREDENTIALS: Indicate who worked on each part of the project, their areas of expertise, and how they qualify as historians or architectural historians according to the federal qualifications set forth in 36 CFR 61. This part of the report can also be used to acknowledge funding or other assistance rendered the surveyor or team.
- PROJECT OBJECTIVES AND METHODOLOGY: Explain why the survey was undertaken and the goals and objectives that the survey project was intended to fulfill. What situations, conditions, planning needs, or other circumstances led to the survey and how and by whom were the objectives developed. List any previous surveys or studies relating to the survey area and define any data gaps or outdated information in these studies that warranted new study. Describe in reasonable detail the work program that was developed to carry out the goals and objectives. Provide a verbal description of the survey area boundaries and set forth the various tasks and components of the project and the order in which they were undertaken. Identify sources—such as the local libraries, university archives, county register of deeds, or interviews and personal records of residents—of historical information to be used in the project.
- DATA LOCATION: List repositories for survey material, such as libraries, archives, planning departments, and SHPO. Indicate where copies of the full set of survey materials, photographs, and copies of the report have been deposited for future access.
- EVALUATION RESULTS SUMMARY:
    - RECONNAISSANCE-LEVEL SURVEY: The evaluation results section will contain recommendations concerning individual properties and areas deemed worthy of further study because of some potential for National Register of Historic Places eligibility. For each individual property, complex property, and district recommended for intensive level survey, provide at a minimum a single paragraph statement that contains a summary description of the resource and rationale for why it is viewed as worthy of intensive level study followed, in the case of resources consisting of multiple properties, by a specific boundary description. Provide a map illustrating the boundaries of areas recommended for intensive level survey (See Maps section of this chapter).
    - INTENSIVE-LEVEL SURVEY: The Evaluation Results section should contain specific recommendations concerning individual and complex properties and districts that appear to meet the National Register criteria along with clearly defined boundaries. For each individual or complex property evaluated as National Register eligible, list the property and its street address (or latitude/longitude to six digits) and municipal unit (if the survey included more than one municipal unit). For a district, provide a detailed boundary description and a rationale for the boundaries selected. For each individual and complex property and districts evaluated as National Register eligible, include a short summary description and significance statement that is similar to the summary paragraphs in National Register nominations. For each proposed district, provide a map that shows the boundaries for the district for inclusion in the Evaluation Results section of the report. The map should be no larger than an 8 ½'' x 11'' format or must be able to be folded to that size in a hard copy of the report.
- PLANNING NEEDS AND RECOMMENDATIONS: If appropriate, include recommendations for other measures that should be undertaken to encourage the future preservation of the survey area's historic resources. These can include recommendations for local historic district designation, for educational programs to increase public awareness (books, videos, websites, programming, etc.), for establishing financial incentive programs to encourage historically sensitive rehabilitations of downtown commercial buildings or

homes in historic districts, for zoning changes, etc. This may be more appropriate for surveys conducted during the Section 106 process. Information should also be included regarding Section 106 recommendations and information on avoiding Adverse Effects on the historic properties.

- PRESERVATION ISSUES AND THREATS: In considering the local preservation environment, the surveyors should note any known threats to buildings in the area and the nature of those threats. The surveyor will also be expected to provide information regarding threats to individual buildings.
- SURVEY MAPS: Provide a complete, final set of survey maps. These maps should be reproducible without color copying capabilities.

SURVEY REPORT COMPONENTS: SECTION TWO

Section Two of the report contains a descriptive overview of the survey area, the historical overview and context narratives, plus evaluation sections relating to the historic themes. This section should be arranged in the following order:

- DESCRIPTIVE OVERVIEW: Provide a summary description of the survey area that defines its physical character, including features such as location and setting, topography, land uses, and general character of the historic resources present. For survey areas that comprise several sections, provide a descriptive overview for each section. The description should begin with general information, including a description of the boundaries (if the survey doesn't encompass an entire community) and a discussion of the area's general character, including the setting and topography. More detailed information about the survey area's physical form and layout and its architectural character should follow. The length of the overviews will vary depending on the size and character of the survey areas. Paradoxically, it seems that for a large survey area, such as an entire community, a relatively short overview will generally make sense, while for a relatively small area, such as a neighborhood, a lengthier overview will often be warranted.
- HISTORICAL CONTEXT: See historical overview section above. This section should include a historical sketch of the development of the community that focuses on settlement patterns, immigrant groups, important industries, and dominant architectural traditions. This section should also include information on themes.
    - o THEMATIC NARRATIVES: The thematic narratives should be prepared as described in the Thematic Narratives section of Chapter 4 and should follow the historical overview for the survey area. Each historical narrative should be followed by evaluation standards for the theme and a list of properties associated with it.
- BIBLIOGRAPHY: The required citation style of Michigan SHPO is the most recent edition of the Chicago Manual of Style. The bibliography should contain a list of all references consulted during the course of the survey.

SURVEY REPORT COMPONENTS: SECTION THREE

Section Three of the report comprises the survey data itself, as well as the following components:

- INDEX LIST OF SURVEYED PROPERTIES: This should be organized by street and number in alphabetical and numerical order. The entry in each surveyed property should

reference the map on which the surveyed property is found (if there is more than one survey map). Individual properties and complex properties at single addresses (generally houses or estates, farms, industrial or institutional complexes, or parks or cemeteries) should be listed alphabetically by street and then numerically by address number. Historic districts should be listed alphabetically by historic name at the beginning of the index list.

- INVENTORY FORMS: Provide a complete set of printed Historic Resource Inventory Forms and a Historic District Inventory Form for all surveyed properties. The forms should be arranged in the same order as the index list. The Michigan SHPO has created a template that includes the mandatory terms for survey in the state (See Appendix D).
- SURVEY PHOTOS: Photographs should be taken in accordance with the above standards.

A survey report is an official document summarizing the results of an important planning activity that will hopefully promote and influence the course of historic preservation activities in the survey area for years to come. The credibility of the report and its conclusions and recommendations can be enhanced by a professional appearance or reduced by an appearance that is less than professional. The final version of the report should be free of typographical and grammatical errors. Reports prepared for SHPO will not be accepted if they contain typographical errors and other unprofessional characteristics. The overall layout and graphics, including mapping, should have a polished, professional appearance.

The survey report is not an academic exercise that will never see the light of day, but rather a public document that will likely be scrutinized for years to come not only by preservationists but also by those seeking to demolish historic properties. The report should be written in an objective tone that clearly demonstrates the significance of the historic resources. Avoid damning historic properties with faint praise. For example, the same building was described in earlier and later versions of the same report as follows:

“In contrast to the Ottawa Street Power Station is the extremely modest Art Deco store at 1136 S. Washington Avenue.”

“In contrast to the grandeur of the Ottawa Street Power Station is the modestly sized Art Deco store front at 1136 S. Washington Avenue. Although the building itself is very small, almost tiny, the unique octagonal windows and pencil-line concrete detailing above the twin entries make this building a distinguished and elegant part of the lively South Washington streetscape.”

The first of these statements says nothing to indicate that this building is significant; in fact, the implication is that it is unimportant, and thus expendable. The second statement, especially when read in combination with another statement about the building on a different page in the report makes unmistakeably clear the importance of the building as evaluated by the report’s authors: “One of the city’s unique structures is the diminutive but jewel-like Art Deco building at 1136 S. Washington.”

DISTRIBUTING SURVEY REPORTS

Every survey should be viewed as an opportunity to help preserve Michigan’s significant cultural resources. The survey products provide an explanation of a community’s development and constitute documentation regarding the location and significance of above-ground resources associated with various themes in a community’s history and architecture. These materials can be a tool for a variety of groups besides SHPO, including:

- Planners, to develop strategies to minimize the impact of development projects on significant resources; to facilitate their responsibilities, under federal law, regarding the protection of cultural resources; and to provide a basis for establishing priorities for the rehabilitation or conservation of neighborhoods
- Historic interest groups that promote local history and the preservation of significant properties or areas, that serve an educational role in the community, and that may be a repository for local historic collections

- Property owners desiring information about their houses or businesses
- Teachers, who use local history and the built environment in classes ranging from social studies to history to art
- The media, which needs background information for news coverage and special reports and programming
- Neighborhood organizations that work to enhance the quality of life in specific areas, and
- Youth groups that may sponsor projects that enhance the environment, including historic resources

Thus, survey reports should be widely available to both governmental and planning agencies and members of the general public. A sufficient number of survey reports should be produced to allow for distribution. The following agencies or organizations should receive a copy of the report:

- Local planning department
- County or regional planning agency
- SHPO (One digital copy and one paper copy)
- Local libraries
- Library of Michigan, Lansing
- Local or regional archives and repositories nearest the survey area, such as
    - Burton Historical Collection, Detroit Public Library
    - Michigan Historical Collections, Bentley Library, University of Michigan
    - Clark Historical Library, Central Michigan University
    - The university archives at Michigan Technological University, Oakland University, and Western Michigan University

We also encourage discussing with the local planning department the possibility of incorporating the survey data into a local Geographic Information System (GIS). These discussions should include SHPO staff.

RECOMMENDATION FOR INTENSIVE LEVEL SURVEY FOR AN AREA RESULTING FROM RECONNAISSANCE LEVEL SURVEY

EXAMPLE: "Island" Survey Area, Sault Ste. Marie

This primarily residential area located on the island formed by the St. Mary's River and the power canal contains a potential National Register-eligible historic district for which precise boundaries should be established as a result of intensive level survey work. The potential district extends east from the county courthouse along portions of Maple, Cedar, Spruce, Carrie, Dawson, Kimball, and Brady Streets and St. James Place in the general area bounded on the west by Bingham, north by Portage, east by Johnston, and south by the power canal and Lyon Street. The area contains a rich concentration of large and often high-style late nineteenth- and early twentieth-century houses, including most of the city's most architecturally distinguished Queen Anne houses plus notable examples of "Free Classic," Tudor, Arts-and-Crafts-influenced, and other styles of houses. It contains two substantial houses built with walls of local pinkish-brown sandstone. A row of very fine Arts-and-Crafts houses lines the south side of Carrie west from Johnston. The area also contains the Neoclassical former Carnegie Library building on Cedar Street plus the Gothic Revival (Catholic) St. Mary's Pro-Cathedral complex, which includes the Art Deco St. Mary's School directly behind the church between Maple and Cedar and the large schoolyard that extends west to Spruce.

The area that appears to merit intensive-level survey is bounded by Portage on the north, Bingham on the west, the power canal on the south, and Johnston on the east, and the two brick bungalows on the east side of Johnston south of Carrie.

RECOMMENDATION FOR NATIONAL REGISTER-ELIGIBLE DISTRICT RESULTING FROM INTENSIVE LEVEL SURVEY

EXAMPLE: Schoolcraft Historic District, Schoolcraft

DESCRIPTION: The recommended Schoolcraft Historic District comprises portions of nine blocks on the village's west side and is centered in the area bounded by Haywood on the east, Eliza on the south, West on the west, and Vienna on the north. It contains many of the community's oldest houses, dating from the 1830s and 40s, and some of its most architecturally distinguished houses, including Greek and Gothic Revival, Italianate, Eastlake, and "Free Classic" buildings. Many of the finest of these houses are located along the two blocks of West Cass Street.

SIGNIFICANCE: The proposed Schoolcraft Historic District occupies much of the original plat of Schoolcraft, laid out in 1831 for owner Lucius Lyons and named by him in honor of his friend, Henry R. Schoolcraft, explorer and Indian agent for the Michigan Territory. The commons Lyons set aside for church and school sites survives, having been made into a park in the 1890s after the only building ever constructed there, a church, was removed. The district, comprising almost the entire village before additional areas were platted beginning in 1835, contains the homes of many of the village's earliest white settlers. These include the person who platted the area for Lucius Lyons; the village's and county's first physician (and later the local Underground Railroad conductor); an owner and a proprietor of the village's first hotel, which stood in this area before Grand Street (US-131) was laid out and became the main street; a part owner of the village's first store; the village's first postmaster; and a participant in Michigan's constitutional convention (and later mayor of Kalamazoo). Anumber of these houses date from the early 1830s and are among the oldest buildings in the southwestern part of Michigan. The district's early

building stock contains examples of a broad range of house forms characteristic of the southern part of Michigan and of the New England and New York State origins of the earliest settlers. They include the I-house, gable-front, upright-and-wing, upright-and-double-wing, and gabled-ell forms. Examples of Greek Revival, Italianate, Gothic, Eastlake, and "Free Classic" houses are present, and some of them, especially along West Cass Street, are unusually distinguished examples of their styles within the overall context of the region's building stock.

BOUNDARY DESCRIPTION: the district boundary begins at the NW corner of lot 57; thence S to NW corner of lot 69; th W along N line of lot 68 to center of West St.; th S to center of Clay St.; th W to rear (W) line of lot 78; th S along rear (W) lines of lots from 78 to 139 and to center of Eliza St.; th E to center of West St.; th S along W line of lot associated with 322 W. Eliza to SW corner of property; th E to SE corner of property; th N to center of Eliza St.; th W to E line of lot 140; th N along E linesof lots 140, 137, 128, and 125 to SE corner of lot 116; th E along S line of lots 117 and 118 to SE corner of lot 118; th N along E line of lot 118 to SE corner of lot 111; th E along S line of lot 110 to center of Hayward St.; th N in center of Hayward to a point in line with N line of lot 62; th W along N line of lots 62 and 63 to center of Center St.; th N to a point in line with N line of lot 57; th W to Point of Beginning. All in Original Plat of the Village of Schoolcraft.

BOUNDARY RATIONALE: This boundary was drawn to include the areas within the original plat containing a concentration of houses relating to the village's earliest days as well as other historically and architecturally significant houses while avoiding those areas in which concentrations of historically and architecturally significant properties are not present.

SURVEY AREA DESCRIPTION FOR A COMMUNITY

EXAMPLE

Port Hope is a small village (population of 360 as of 1980) located on the shore of Lake Huron in the Thumb region of Michigan's Lower Peninsula. The Thumb, bounded on the east by Lake Huron north of Port Huron and on the northwest by Saginaw Bay, is a rural, agricultural area generally of low, slightly rolling topography. The principal part of Port Hope from approximately Main Street west lies on a nearly level plain that extends inland in all directions. East of Main Street the land drops off a short distance to a lower terrace along the lakeshore itself. The village is surrounded on the land side by farm country with scattered stretches of forest. A modern county park and several campgrounds and trailer parks occupy much of the lake frontage in the village, but to the north and south the shoreline is wooded and in some cases swampy. US-25 is the principal commercial street, passing through the small central business district, with its handful of clapboards and brick Late Victorian buildings, in the two blocks between School Street and Portland Avenue. US-25 southeast of the point where Main Street cuts off from it follows a modern alignment that cuts diagonally across the historic platted patterns of streets. Main Street on either side of the business district and the streets to the west—First, Second, Third, State, and School—is the residential portion of town and contains a mixture of mostly modest late nineteenth- and twentieth-century houses plus two older churches. The lakeshore terrace to the east historically was the site of mills and elevators, and presently contains several elevator complexes and other commercial enterprises, plus free-standing chimney stacks from long-ago-destroyed saw and planing mills. It appears that many of the streets in the north and southeast parts of town shown in the 1890 map as platted were never opened.

SURVEY AREA DESCRIPTION FOR A NEIGHBORHOOD

EXAMPLE

River Point is bounded on the north and west by the Grand River, east by the Red Cedar River, and south by the railroad line south of South Street, which forms the southern edge of the original part of Lansing platted in 1847. The neighborhood comprises two components, the commercial corridor along South Washington, which spills over slightly onto the side streets, and the larger residential area along Hazel, Elm, South, Grand, and Platt to the east. River Point's distinct edges define the neighborhood's character and make it a place apart from the rest of the city.

The South Washington corridor between the river and the railroad tracks possesses much visual interest because of the variety of older buildings present—from one of the city's largest early twentieth-century apartment buildings to a Spanish Mission-style former gas station to a Moderne enameled metal panel bowling alley to a Neoclassical bank building to one of Lansing's Art Deco jewels to a turn-of-the-century railroad station. The station is located just outside of the survey area; it is listed in the National Register of Historic Places.

The corridor's buildings have survived reasonably intact and restorable despite years of neglect and underutilization. Much of the commercial building stock consists of early twentieth-century two-story Commercial Brick blocks in which the facades rely for their decorative interest not on historical styling but on the brickwork itself. The most commonly seen trademarks of Commercial Brick are panels of brickwork and corbelled brickwork below the upper cornices or roofline. The range of buildings at 1131-1149 S. Washington, although as simply detailed as any Commercial Brick block in the city, are unusual for the uniform façade design with slightly recessed brickwork panels in the friezes carried throughout. The four-store front building at 1000-1006 displays the most intricate brickwork paneling of any of the area's numerous examples. Alternating panels of horizontal stretcher bricks and diagonal stretchers flanking central lozenge ornaments—the panels outlined by bands of headers with square blocks at the corners—stretch across the façade at frieze level. The three-storefront building at 1202-1206 S. Washington (each section of the building today is treated differently, with the central third clad in 1960s-looking metal sheathing that should come off one day) displays a robust Commercial Brick corbelled cornice in which projecting stretchers alternate with recessed headers. The Popoff Meat Co.'s northerly building employs an even more eye-catching corbelling technique in its cornice. In the alternating tiers of projecting and recessed corbelled brickwork, the recessed tiers begin one course above the projecting ones. This results, when sunlight falls on the façade, in a checkerboard-like appearance. Like Commercial Brick buildings elsewhere in Lansing, the South Washington ones exhibit considerable variety in brick hues and textures.

One of the city's unique structures is the diminutive but jewel-like Art Deco building at 1136 S. Washington. This symmetrical two-storefront limestone-clad building displays octagonal shop windows, fluted horizontal banding, chevrons, and dramatic striping on the façade. The façade is completely intact, including the doors with their streamlined push bars.

Another landmark, although not a commercial building, along South Washington is the Washington Arms Apartments located just south of the Grand River. Along with the Porter, located on Townsend at Lenawee, the massive red brick Washington Arms is probably the largest early twentieth-century apartment building in a city which until well into the twentieth-century century was almost exclusively a community of single-family houses, with only a relatively small number of two-family and townhouse buildings.

The streets east of Washington comprise the bulk of the River Point residential neighborhood (a few residential buildings are also found west of Washington, and notice will be taken of one of them in a few paragraphs). The River Point neighborhood is characterized by narrow streets and, except north of Hazel, small lot sizes. Houses stand close by one another and close to the street. Far from being drawback,

these factors along with the abundant shade from large trees give the neighborhood an intimate scale that is one of its most appealing features.

The houses in River Point appear to date primarily from the 1890s to the 1920s. There are none of the larger and more elaborately detailed houses found in some other Lansing neighborhoods. The houses are generally simple and of modest scale. Some of the larger of the oldest houses are narrow-fronted and deep two story, cross-gable houses such as 1135 S. Grand and a brick example at 1145 S. Grand. A number, such as 215 Hazel and 1134 Platt, are gable-front buildings where the entrance stands at the back of a shed-roof side porch. Among the neighborhood's early twentieth-century homes, the two-story square-plan "foursquares" found in other Lansing neighborhoods are present along with a small number of bungalows. The bungalows tend to display simple Arts-and-Crafts-inspired detailing including exposed rafter ends below the broadly projecting roofs and, in the case of 1140 S. Grand, door and window trim with elongated lintels and slanting sides. A small number of Colonials, including narrow and deep Dutch Colonials with their gables to the street such as the one at the southeast corner of Hazel and Grand, are also present. A gable-front turn-of-the century-looking Colonial house at 222 Elm stands out among the neighborhood's dwellings because of its tripartite, with arched center, Palladian-inspired window in the front gable.

Most houses in River Point occupy narrow-fronted and deep lots and thus embody similarly narrow and deep forms. Elm Street presents virtually the only exceptions to this general pattern. A stuccoed, hip-roof, two-family house of Arts-and-Crafts inspiration—the only building constructed as a two family house noted in the neighborhood, at the southwest corner of S. Grand—and a broad-fronted gambrel-roof Dutch Colonial with shed dormer, located on Elm's north side between Grand and Platt, are highly visible buildings because of this broad-fronted orientation.

The neighborhood's only church building stands at the south end of the area on South Street between Grand and Platt. It is a cross-gable, early twentieth-century, auditorium-type church building with a square-plan tower near the façade's midpoint. Simple bargeboards mark the eaves.

The short east-west streets west of Washington retain few buildings. The most notable of them—really one of the outstanding buildings of the neighborhood—stands at 117 S. South. This two-story, symmetrical-front building, presumably once an apartment house, sports an Arts-and-Crafts façade of brick of various hues from red orange to brown that is divided into three vertical bays by boldly projecting piers, the central ones rising well above the tiled pent roofs that top the bays. The central bay's entry and broad windows in either side bay, set within segmental arches and panels of header brick outlined by stretcher brick (itself a reversal of the typical panel treatment), separates the first-floor openings from those above. Another pent-roof building, a smaller one-story commercial building with an arched central entry, stands next door to the west at 121.

River Point today all but turns its back to the river. Although some streets and houses stand close to the Grand and Red Cedar, steep, thickly wooded banks conceal the water from view. The city has developed the small River Point Park at the actual confluence of the Grand and Red Cedar, but, it seems, more could be done to make the rivers' proximity a community asset.

UPDATING PREVIOUS SURVEYS

Areas may require re-surveying because the existing data has become outdated, a higher level of survey is required (an intensive-level survey will replace an old reconnaissance-level one), or the quality of the old survey is unreliable. Whatever the reason, past survey activity may provide information useful for the present project, including:

- Existing site-specific records (inventory cards, forms, or database records);
- Research that can contribute to the current research effort;
- Recommendations regarding eligibility;
- Districting proposals.

The new survey should build upon the old one. The old thematic narratives should not be used as is, but the new survey should be seen as an opportunity to revise and expand them. The aim of a new survey should be to provide survey materials meeting current standards for all properties in the survey area that have previously been surveyed and that meet the survey criteria developed for the re-survey project. A re-survey project should generally be performed at the intensive level; it usually makes little sense to re-survey previously surveyed properties unless the survey will generate additional information. Old surveys often omitted features of complex properties such as carriage house/stable buildings and agricultural outbuildings that would be included in current intensive-level surveys. The new survey provides an opportunity to obtain complete survey data that should not be missed.

The new survey report should include all of the standard products as well as any newly surveyed properties within the re-survey area.

THEMATIC SURVEYS AND CONTEXT STUDIES

Thematic survey is the survey of properties relating to a specific property type or historic theme. Thematic surveys of industrial and engineering sites, highway bridges, post offices, and state parks have been carried out at the statewide level, and myriad other property types or themes such as vernacular log buildings, outdoor sculpture, designed historic landscapes, and the automobile industry could be the subjects of statewide thematic surveys. Thematic surveys within single counties or larger cities are equally feasible.

A survey project in Grand Rapids included thematic surveys of city parks, public school buildings, and cemeteries. Surveys of public schools, apartment buildings, and banks in the city of Detroit have been completed. The Michigan SHPO has undertaken these context studies as a way to better assist planning efforts in these regions. Thematic surveys could involve important aspects of local history, such as the struggle for Civil Rights in Detroit or Detroit's rich twentieth-century heritage as a center for jazz and other forms of popular music. A survey of sites associated with the history of popular music in Detroit, for example, might seek to identify birthplaces and homes of musicians, recording studios, and clubs, ballrooms, and other places where locally and nationally important performers and groups played. The possibilities for thematic surveys and context studies are endless.

Thematic surveys differ from other survey types by requiring an initial property-specific research phase to identify the specific properties to be surveyed or to locate the areas likely to produce resources that merit survey. Standard sources of information such as published histories, typically used for surveys, may not be as useful in thematic surveys, and research in specialized sources of information appropriate to the project will be needed. A statewide survey of historic railroad bridges might require a search for railroad company records, engineering and railroad journals and bridge company records and catalogs that might provide information on specific structures, and a review of maps to locate likely points for major bridges. Surveys of Civil Rights struggle-related sites or popular music-related sites in Detroit would probably require numerous oral history interviews. A survey of the Finnish farmsteads in the Upper Peninsula would likely require research in old maps and census records to determine where the concentrations of Finnish settlements were located.

Surveyors will need to devise research strategies appropriate for identifying and documenting the resources to be surveyed. Persons with specialized knowledge of the survey's subject matter should be involved in the project at the earliest planning stage. In carrying out a thematic survey, the general instructions for intensive-level survey provided here should be followed. However, a thematic survey must begin with a research phase both to document the theme itself and to identify and document the associated properties. The thematic research will lead to the preparation of a single thematic narrative that includes discussion of associated property types.

Many thematic surveys are done under contract with SHPO. These projects often involve the preparation of inventory forms and a Multiple Resource Documentation Form for the National Park Service. In addition to this form, these surveys must include a separate survey report following the guidelines outlined in this document. Consultants should utilize site forms following the example in Appendix D for the creation of their inventory forms. These items must also be entered in the MiSHPO system as outlined in this document.

SURVEY AND SECTION 106

As a part of their compliance with Section 106 of the National Historic Preservation Act, federal agencies and their designees have the responsibility to identify historic properties that may be affected by an undertaking. An undertaking is a federally assisted or licensed project, such as housing rehabilitation and demolition, streetscape improvements, new road construction and road reconstruction or realignment, airport expansions and renovations, water and sewer projects, new bank branches, railroad line abandonments, and communication towers. Under Section 106, federal funding or licensing agencies (or their designees when permitted under federal regulations) must provide SHPO with data on historic properties that might be affected by their proposed projects along with substantive comments on the eligibility of those properties. The submission of this information is a prerequisite to obtaining comments from SHPO on the effects of the projects on historic above-ground resources. Projects that involve both above-ground and below-ground disturbances should also contact the State Archaeologist to conduct appropriate file reviews of below-ground sites in the project area.

The APE for a project should be defined in consultation with SHPO. **Please note that the area of potential effects (APE) is not simply the project's physical boundaries or right of way.** It is important to understand this. The APE is defined as the geographic area or areas within which an undertaking may directly, or indirectly, cause changes in the character or use of historic properties. The area of potential effects is influenced by the scale and nature of an undertaking and may be different for different kinds of effects caused by an undertaking. In defining the APE, you must consider not only physical effects but also visual, auditory, and sociocultural (i.e. land use, traffic patterns, public access) effects.

The potential National Register of Historic Places eligibility of properties that may be affected by a federally assisted or licensed project must be reviewed in the context of the neighborhood or area in which they are located. The agency requesting SHPO's review must provide sufficient information to answer the question, "What are the historic properties either listed in or eligible for listing in the National Register of Historic Places within the area of potential effect (APE) for the project?" This includes determining not only whether affected properties may be individually eligible for the National Register, but also whether they may contribute to the historic character of a larger area or district that as a whole meets the National Register criteria. Competent professionals meeting the federal professional qualifications for historian and architectural historian should perform the work.

WORK PROGRAM

Federal agencies or their federally delegated designees ("Responsible entities" for HUD-funded projects) must perform the following in order to provide the basic information SHPO requires. This information will be used to make informed determinations of eligibility and effect for properties in the APE:

1. A visual inspection of the exterior of each property in the APE and of the surrounding neighborhood to
    a. Evaluate the architectural character and integrity
    b. Determine if properties in the APE may be part of a National Register-eligible district and if so, to define the district's boundaries.
2. Contact SHPO to
    a. Review National Register listings for the community
    b. Determine whether SHPO has previously established firm boundaries for a National Register-eligible district in the area.
3. Research the properties in the APE and document their histories, using standard sources such as
    a. Historic atlases and plat books
    b. Directories and published sources such as county and local histories
    c. Tax records
    d. Interviews with current and past property owners, local historians, and long-term residents

APPENDIX A

HISTORIC ARCHITECTURE SURVEY GLOSSARY OF TERMS

These definitions were obtained from the National Park Service National Register Bulletins 15, 24, and 16a.

ARCHITECTURE CLASSIFICATION – Item on the National Register form calling for the entry of an architectural style or other term by which the property can be identified.

BUILDINGS – A building, such as a house, barn, church, hotel or similar construction is created to shelter any form of human activity. Building may also refer to a historically and functionally related unit, such as a courthouse and jail or a house and barn. Examples include stables, sheds, garages, courthouses, city halls, social halls, commercial buildings, libraries, factories, mills, train depots, stationary mobile homes, theaters, schools, and stores.

DISTRICT – A district possesses a significant concentration, linkage, or continuity of sites, buildings, structures, or objects united historically or aesthetically by plan or physical development. Examples include college campuses, central business districts or other commercial areas, residential areas, industrial complexes, civic centers, rural villages, large farms, ranches or estates, and large landscaped parks.

FORM CLASSIFICATION – the item on the National Register form calling for the architectural form or other term by which the property can be identified.

HISTORIC CONTEXT – An organizing structure for interpreting history that groups information about historic properties that share a common theme, common geographical area, and a common time period. The development of historic context is a foundation for decisions about the planning, identification, evaluation, registration, and treatment of historic properties, based upon comparative historic significance.

HISTORIC INTEGRITY – the unimpaired ability of a property to convey its historical significance.

HISTORIC RESOURCE – a building, site, district, object, or structure evaluated as historically significant.

IDENTIFICATION – the process through which information is gathered about historic properties.

LANDSCAPE – A landscape is a collection of organized features that can range from something as small as a birdbath to large fields or orchards. The U.S. Secretary of the Interior has defined the following six components of a landscape that must be identified and documented if the character of the landscape property is to be understood: spatial organization and land patterns; topography; vegetation; circulation; water features; and structures, site furnishings, and objects.

OBJECT – The term object is used to distinguish from buildings and structures those constructions that are primarily artistic in nature or are relatively small in scale and similarly constructed. Although it may be, by nature or design, movable, an object is associated with a specific setting or environment, such as statuary in a designed landscape. Examples include sculpture and statuary, monuments, fountains, fences and streetlights.

PROPERTY TYPE – a grouping of individual properties characterized by common physical and/or associated attributes.

RESOURCE – any building, structure, site or object that is part of or constitutes a historic property.

RESOURCE TYPE – the general category of property – building, structure, site, district, or object – that may be listed in the National Register.

SETTING – quality of integrity applying to the physical environment of a historic property.

SIGNIFICANCE – Importance of a historic property as defined by the National Register criteria in one or more areas of significance.

SITE – A site is the location of a significant event, a prehistoric or historic occupation or activity, or a building or structure, whether standing, ruined, or vanished, where the location itself possesses historic, cultural, or archaeological value regardless of the value of an existing structure. Examples commonly encountered in above-ground surveys include estate and other grounds, gardens, ruins of historic buildings and structures, cemeteries, parks, and designed landscapes.

STRUCTURE – The term structure is used to distinguish from buildings those functional constructions made usually for purposes other than creating shelter. Examples include bridges, tunnels, dredges, fire towers, canals, dams, power plants, water purification and sewage treatment plants, water towers, corncribs, silos, roadways, windmills, grain elevators, kilns, railroad grades, systems of roadways and paths, boats and ships, railroad locomotives and cars, carousels, bandstands, gazebos, and aircraft.

STYLE – in this case, it is the architectural style that is not on the list of the pre-defined NPS-acceptable terms for the National Register Form. If “other” is selected for the Architectural Classification field, then Style should indicate what the “other” is.

SURVEY – A survey is a systematic search for properties that possess or appear to possess significance to national, state, or local history. Survey is the process of identifying and gathering data on properties that may be historic. It includes field survey, the physical search for and recordation of basic information about historic and potentially historic properties; background research to establish the historic context for the properties within the project area; and historical research on surveyed properties.

THEME – a trend or pattern in history or prehistory relating to a particular aspect of cultural development, such as dairy farming or silver mining.

APPENDIX B

FARMSTEAD AND HISTORIC LANDSCAPE SURVEY STANDARDS

Urban, suburban, and rural survey areas may contain properties and areas that possess significance as historic landscapes. The U.S. Secretary of the Interior has defined the following six components of a landscape that must be identified and documented if the character of the landscape property is to be understood: spatial organization and land patterns; topography; vegetation; circulation; water features; structures; site furnishings; and objects. The degree of importance of any of these features depends on the landscape and its use.

The most likely types of historic landscapes encountered in the field are the Historic Designed Landscape and the Rural Historic Landscape. Before beginning work, surveyors should review *The Secretary of the Interior's Standards for the Treatment of Historic Properties with Guidelines for the Treatment of Cultural Landscapes*; National Register Bulletin 18, *How to Evaluate and Nominate Designed Historic Landscapes;* and National Register Bulletin 30, *Guidelines for Evaluating and Documenting Rural Historic Landscapes*, for insights into identifying and documenting these important historic resources.

A Historic Designed Landscape is defined in Bulletin 18 as a landscape:

- Significant as a design or work of art
- Consciously designed and laid out either by a master gardener, landscape architect, architect, or horticulturalist to a design principle, or by an owner or other amateur according to a recognized style or tradition, or
- That has a historical association with a significant person, trend, or movement in landscape gardening or architecture, or a significant relationship to the theory or practice of landscape architecture

Historic designed landscapes may include parks, squares and other public spaces, cemeteries, parkway or boulevard systems, small residential grounds, estates, campus or institutional grounds, gardens, golf courses, and planned subdivisions and communities, including mobile-home parks/manufactured housing developments.

A Rural Historic Landscape is defined in Bulletin 30 as:

- A geographic area that historically has been used by people, or shaped or modified by human activity, occupancy, or intervention, and that possesses a significant concentration, linkage, or continuity of areas of land use, vegetation, buildings and structures, roads and waterways, and natural features. Rural landscapes often reflect the day-to-day occupational activities of people engaged in traditional work activities such as mining, fishing, and various types of agriculture. Often, they have developed and evolved in response to both the forces of nature and the pragmatic need to make a living.

Rural historic landscapes often contain large acreage and proportionally small numbers of buildings and structures compared to other types of historic properties. Examples of rural historic landscapes in Michigan include: agricultural districts, industrial districts of a series of mine complexes or remnants, a fishing village or complex, and a district of recreational camps.

SURVEYING HISTORIC LANDSCAPES

Survey forms should be customized in consultation with SHPO for a historic landscape depending on whether the landscape forms a single complex property, such as a park, cemetery, residential grounds, an estate, or a number of complex properties. For single complex property surveys, any feature that appears several times on the landscape such as a fence or wall system, should be recorded on a single form with the quantity included. For cemeteries, records should be created for all public monuments and memorials, such as veteran memorials. Private monuments and memorials should be surveyed when they mark the resting place of historically significant individuals, when they possess special artistic

merit or unique design, or when they are rare examples of a type (e.g. iron cross markers from old Catholic cemeteries).

For multiple complex properties forming a historic landscape, each property should have its own site form. Examples include the following:

- A Rural Historic Landscape that is a rural agricultural district consisting of a group of farms, each of which contains historic features that require survey;
- A Designed Historic Landscape that is a planned residential district in which each individual property contains historic features that require survey.

Survey data for a Rural Historic Landscape should be captured on both a survey form and in the description field as appropriate. Some of the items collected could include:

- Land uses and activities
- Patterns of spatial organization
- Response to the natural environment
- Cultural traditions
- Circulation networks
- Boundary demarcations
- Vegetation related to land use
- Buildings, structures, and objects
- Clusters
- Archaeological sites
- Small-scale elements

Survey data for Designed Historic Landscapes should be captured on both a survey form and in the description field as appropriate. Some of the items collected could include:

- Overall form and plan of the landscape.
- Approximate size of the landscape—Convey the scale of the landscape in terms of acres or square miles, as appropriate.
- Topography—Describe whether the land is flat, rolling, hilly, or varied in relief.
- Natural features—Describe natural features, such as rivers, lakes, hills, or bluffs that help define the landscape.
- Circulation systems of roads, paths, trails, etc.
- Spatial relationships and orientation, such as symmetry, asymmetry, and axial alignment.
- Views and vistas in to and out of the landscape.
- Vegetation—Ideally, describe the common name with caliper for trees and heights for shrubs (and put this information onto maps). At the least, describe the primary types and locations of vegetation. Mention the extent of tree cover, using appropriate terms such as grove, scattered trees, forest, wooded area, and specimen tree. If possible, name the species of trees or describe whether trees are coniferous (evergreen) or deciduous. Include the general maturity of trees. Use a similar approach to describing shrubs and their arrangement on the landscape. Flowers and other low-growing plants should be described in terms of their placement on the landscape: in beds, naturalistic plantings, planters, or specialty gardens.
- Bodies of water such as pools, fountains, lakes, streams, and cascades.

- Number and general character and location of buildings, structures, and objects present.

Photography should include an appropriate number of images to thoroughly document the entire district and individual complexes or features. The views should be taken from different directions and include one or more that illustrate the street frontage.

A single survey map should be prepared for each surveyed complex in accordance with the general survey mapping instructions. The map should include the entire district, not just areas containing the buildings. All surveyed resources should be plotted and labeled. The survey map should also illustrate those important features not surveyed but included on the survey form for the entire property.

SURVEYING FARM PROPERTIES

Farm properties commonly consist of farmstead areas containing houses, barns and other outbuildings plus the remainder of the farm properties, which may include a combination of features such as crop and pasture areas, woodlots, orchards and gardens, lanes, windbreaks, and ponds. Additional buildings such as hay barns and migrant housing clusters may stand outside of the main farmstead area. Small-scale features such as fencing, windmills, wells, and bridges may also be present. These human-built and natural elements plus the overall features of land use and circulation patterns define the character of farm properties.

A survey of farm properties should provide information on the entire property, including a comparison of the current historic patterns of land use and the physical layout as far as it can be determined. It should provide information on all buildings, structures, and other component features.

The surveyor must complete survey forms for the entire property and also individual survey forms for each of the buildings, structures, and objects regardless of age. Survey forms must also be made to cover all examples of any features that appear several times on the landscape such as fencing or wall systems. Historic vegetation associated with human occupation and use—such as windbreaks, tree lines along roads or drives, specimen trees, garden beds, and sugarbushes—should be included on survey forms, when historic information on the origins and uses of these features can be obtained. If information on the origin and use of the features is not found then they should be described and mentioned in the survey form for the larger farmstead.

Photography will include an appropriate number of images to thoroughly document the entire farm and individual features. The views should be taken from different directions and include one or more that illustrate the street frontage.

A single survey map must be prepared for each surveyed farm in accordance with the general survey mapping instructions. The map must include the entire property, not just the area containing the buildings. All surveyed resources must be plotted and labeled. The survey map should also illustrate those important features not surveyed but included on the survey form for the entire farm.

APPENDIX C

CONTRACTING SURVEYS

Survey Sponsors seeking consultants for survey work should develop a Request for Proposal (RFP) for the project. A clear RFP, with work and work products explicitly stated, helps consultants prepare more accurate budgets. If the work program is vague, consultants may have to compensate by pricing for unknown or unclear aspects of the work, and disagreement over the expected products may result at the end of the project. It is a good idea to request that the SHPO Survey Coordinator review the RFP before it is sent out to consultants.

The RFP should define the work program and products as fully as possible. It should clearly and thoroughly define:

- The work the consultant is expected to perform;
- The products—including the number of copies—to provide at the end of the project;
- The boundaries of the survey area, clearly defined in writing and illustrated by a map or series of maps;
- The expectations for the level of property-specific research, including what sources of information the consultant will be expected to use for all properties, and what additional research will be required for a specific number of apparently more significant properties, if that information is available;
- The total number of properties to be surveyed and a breakdown of the numbers by level of research, if possible;
- The time frame within which the project must be completed;
- Services or materials that may be provided to the consultant at the consultant's request; and
- Expectations for meetings the consultant will be expected to attend or presentations the consultant will be expected to make.

The RFP should clearly define the information that consultants must submit in their proposals, including:

- A thorough description of the work to be performed and the final products to indicate whether or not consultants have a clear understanding of what will be required;
- A plan of action for accomplishing the work. This should include a breakdown of the work by components and personnel and a schedule with time frames for each component;
- Educational background and related work experience of the personnel working on the project;
- Writing samples for personnel involved in preparing the report;
- Professional References.

Finally, the RFP should specifically list the criteria against which proposals will be evaluated. The criteria should award points to proposals that demonstrate:

- A solid understanding of the work and products required;
- An adequate program and realistic time frames for successful completion of the project; and
- Personnel with the necessary educational background, work experience, and proven track record of successfully completed projects.

Cost is obviously an important consideration, but no proposal should be considered unless it fully meets the evaluation criteria set forth above.

MISHPO TERMS LIST

Below is a list of some of the acceptable MiSHPO terms.

OWNER TYPE:

- Private
- Public-Local
- Public-State
- Public-Federal

PROPERTY TYPE:

- Apartment building
- Bridge
- Commercial district
- Duplex
- Farm
- Lighthouse
- Railroad depot
- Residential district
- Rowhouse
- Service station
- Ship

FORMS

BUILDING FORMS

- A-frame Building
- Octagon Building
- Polygon Building
- Quonset Building – use for Quonset or other arch-rafter structure with semi-cylindrical roof and non-existent side walls
- Round Building

HOUSE FORMS

- American Foursquare
- Basilica Plan House – use in place of Hen and Chicks
- Bungalow
- Cruciform House
- Cup and Saucer House
- Front-gabled House
- Gabled Ell
- Half Basilica House
- Hall and Parlor House
- Hen and Chicks – use Basilica Plan

- I-House
- New England Large House
- New England 1½ Cottage
- Pyramidal Cottage
- Ranch House
- Upright and Double Wing House
- Upright and Wing
- Basement Barn
- English Barn
- Pennsylvania Barn
- Pole Barn
- Southwestern Michigan Dutch Barn

COMMERCIAL BUILDING FORMS: Use the following terms as appropriate. See Richard Longstreth's *The Buildings of Main Street* (Walnut Creek, CA: AltaMira Press, 2000).

- Arcaded Block
- Enframed Block

Note: The text of Form N–3 does not, and these amendments will not, appear in the *Code of Federal Regulations.*

■ 13. Amend Form N–3 (referenced in §§ 239.17a and 274.11b), Cover Page, by adding a new paragraph immediately after the sentence ["t]he Commission also may use the information provided on Form N–3 in its regulatory, disclosure review, inspection, and policy making roles" To read as follows:

* * * * *

A Registrant is required to disclose the information specified by Form N–3, and the Commission will make this information public. A Registrant is not required to respond to the collection of information contained in Form N–3 unless the Form displays a currently valid Office of Management and Budget ("OMB") control number. Please direct comments concerning the accuracy of the information collection burden estimate and any suggestions for reducing the burden to Secretary, Securities and Exchange Commission, 100 F Street NE, Washington, DC 20549. The OMB has reviewed this collection of information under the clearance requirements of 44 U.S.C. 3507.

* * * * *

Note: The text of Form N–CEN does not, and these amendments will not, appear in the *Code of Federal Regulations.*

■ 14. Amend Form N–CEN (referenced in § 274.101) by replacing the Instruction following Item F.3 and replacing Item F.18 to read as follows:

* * * * *

Part F: Additional Questions for Unit Investment Trusts

* * * * *

Item F.3. * * *

Instruction. If the answer to Item F.3 is yes, respond to Item F.12 through Item F.19. If the answer to Item F.3 is no, respond to Item F.4 through Item F.11, and Item F.17 through Item F.19.

* * * * *

Item F. 18. Reliance on rule 12d1–4. Did the Registrant rely on rule 12d1–4 under the Act (17 CFR 270.12d1–4) during the reporting period? [Y/N]

* * * * *

Note: The text of Form N–PX does not, and these amendments will not, appear in the *Code of Federal Regulations.*

■ 15. Amend Form N–PX (referenced in § 274.129), Cover Page by removing "§§ 239.24 and 274.5 of this chapter" and adding, in its place, "17 CFR 239.24 and 274.5".

Note: The text of Form N–MFP does not, and these amendments will not, appear in the *Code of Federal Regulations.*

■ 16. Amend Form N–MFP (referenced in § 274.201), in Item A.14.c. by removing the term "A.14.a–c." and adding, in its place, the term "A.14.a–b."

PART 275—RULES AND REGULATIONS, INVESTMENT ADVISERS ACT OF 1940

■ 17. The authority for part 275 continues to read, in part, as follows:

Authority: 15 U.S.C. 80b–2(a)(11)(G), 80b–2(a)(11)(H), 80b–2(a)(17), 80b–3, 80b–4, 80b–4a, 80b–6(4), 80b–6a, and 80b–11, unless otherwise noted.

* * * * *

Section 275.204–2 is also issued under 15 U.S.C. 80b–6.

* * * * *

Section 275.204–5 is also issued under sec. 913, Public Law 111–203, sec. 124 Stat. 1827–28 (2010).

* * * * *

§ 275.204–2 [Amended]

■ 18. In § 275.204–2 amend paragraph (a)(15)(ii) by removing "." and adding, in its place, "; and".

§ 275.204–3 [Amended]

■ 19. In § 275.204–3 amend paragraph (b) by removing "Subject to paragraph (g), you" and adding, in its place, "You".

§ 275.204–5 [Amended]

■ 20. In § 275.204–5 amend paragraph (e)(1) by removing "§ 275.204–1(b)(3)" and adding, in its place "§ 275.204–1(b)".

§ 275.206(4)–1 [Amended]

■ 21. In § 275.206(4)–1 amend paragraph (b)(2)(i) by removing "," and adding in its place ";".

PART 279—FORMS PRESCRIBED UNDER THE INVESTMENT ADVISERS ACT OF 1940

■ 22. The authority for part 279 continues to read, in part, as follows:

Authority: The Investment Advisers Act of 1940, 15 U.S.C. 80b–1, *et seq.*, Public Law 111–203, 124 Stat. 1376.

Note: The text of Form ADV does not, and these amendments will not, appear in the *Code of Federal Regulations.*

■ 23. Amend Form ADV (referenced in § 279.1) by:

■ a. In General Instruction 4 to Form ADV removing "Section 10 of Schedule R" and adding, in its place, "Section 4 of Schedule R"; and

■ b. In the Instruction to Section 4.B.7 of Schedule R removing "pre-fill Schedule B with the same indirect owners you have provided in Schedule B" and adding, in its place, "pre-fill the chart below with the same indirect owners you have provided in Schedule B for your *filing adviser*".

Curation of Federally Owned or Administered Archeological Collections

AGENCY: National Park Service, Interior.

ACTION: Final rule.

SUMMARY: The National Park Service amends regulations governing the curation of federally owned or administered archeological collections to establish definitions, standards, and procedures to dispose of material remains that have insufficient archeological interest. This rule promotes more efficient and effective curation of archeological collections.

DATES: This rule is effective May 16, 2022.

FOR FURTHER INFORMATION CONTACT: Karen Mudar, Archeology Program, National Park Service, 1849 C Street NW, Washington, DC 20005, 202–354–2103, email: *karen_mudar@nps.gov.* Individuals in the United States who are deaf, deafblind, hard of hearing, or have a speech disability may dial 711 (TTY, TDD, or TeleBraille) to access telecommunications relay services. Individuals outside the United States should use the relay services offered within their country to make international calls to the point-of-contact in the United States.

SUPPLEMENTARY INFORMATION:

Background

Authority To Promulgate Regulations

The Archaeological Resources Protection Act (ARPA; 16 U.S.C. 470aa–mm) authorizes the Secretary of the Interior (the Secretary) to promulgate regulations for the disposition of archeological and other resources recovered under the authority of ARPA, the Reservoir Salvage Act (RSA; 54 U.S.C. 312501–312508), and the Antiquities Act (54 U.S.C. 320301–320303). 36 CFR part 79's disposition process for resources recovered under ARPA, RSA, and the Antiquities Act is authorized thereunder. In addition, the National Historic Preservation Act (NHPA; 54 U.S.C. 302107 and 306131) authorizes the Secretary to promulgate regulations for the proper curation of archeological collections created under ARPA, RSA, and NHPA. 36 CFR part 79's curation requirements for resources recovered under ARPA, RSA, and NHPA are authorized thereunder. The Department of the Interior's Departmental Manual entitled ''Protection of the Cultural Environment'' (519 DM 2.3D) requires the Departmental Consulting Archeologist (DCA), located within the National Park Service (NPS), to develop regulations concerning the preservation of prehistoric and historic material remains of archeological interest under ARPA.

Regulatory History

The regulations at 36 CFR part 79 establish definitions, standards, procedures, and guidelines to be followed by Federal agencies to preserve collections of prehistoric and historic material remains and associated records that generally include those resulting from a prehistoric or historic resource survey, excavation, or other study conducted in connection with a Federal action, assistance, license, or permit.

As currently written, 36 CFR part 79 does not discuss processes for Federal agencies to dispose of particular material remains from archeological collections. It is important for Federal agencies to establish appropriate methods of disposal because prehistoric or historic material remains improperly disposed of could later be rediscovered and misinterpreted by archeologists or others as evidence of activity in the distant past. A proposed rule to establish procedures for discarding particular material remains from Federal collections was published in the **Federal Register** in 1990 (55 FR 37670, September 12, 1990). A final rule was never published. Instead, the DCA focused on the proper curation of federally owned or administered collections and left the subject of disposal of material remains for a future rulemaking.

In recent years, renewed interest from Federal agencies to address the issue of deaccessioning certain material remains has led to the promulgation of this rule. Specifically, Federal agencies such as the Department of Defense asked the DCA to help them find solutions to the growing costs of managing archeological collections. The NPS published a proposed rule in the **Federal Register** on November 18, 2014 (79 FR 68640).

Final Rule

This rule establishes procedures for the disposal of particular material remains of insufficient archeological interest that are held in federally owned or administered archeological collections. The procedures are not intended to apply to entire collections. Material remains refers to artifacts, objects, specimens, and other physical evidence, including human remains, of a historic or prehistoric resource. Federal agencies are responsible for ensuring that disposition of material remains is conducted in accordance with this rule and 36 CFR 79.7 ''Methods to fund curatorial services.'' This rule does not affect any material remains defined as ''cultural items'' by the Native American Graves Protection and Repatriation Act (NAGPRA; 25 U.S.C. 3001 *et seq.*) and subject to that statute. NAGPRA cultural items include Native American human remains, funerary objects, sacred objects, or objects of cultural patrimony.

In addition to providing a mechanism for appropriate and carefully considered disposition, this rule will improve the curation of federally owned or administered archeological collections, such as by promoting more effective space and cost management. This rule addresses many of the comments submitted in 1990 by incorporating independent advice and opinions supplied by numerous experts that were consulted between 2005 and 2013. The NPS stresses that the disposition process laid out in this rule must be employed as part of a comprehensive collection management program that emphasizes collection stewardship and responsible accessioning practices. The best deaccession policy is a good accession policy. This rule provides measures to allow for deaccessioning only as a last resort. The NPS recommends that, in addition to proposing deaccession, agencies implement carefully designed field collection policies and create and implement clear and thoughtful scope of collections statements. Consistent with the Secretary's authority to promulgate regulations for ultimate disposition of certain material remains, this rule uses the term disposition throughout. The NPS acknowledges the museum practice of deaccessioning will be an integral and parallel part of the disposition process described in this rule.

In addition to adding a new Subpart E—Disposition of Particular Material Remains (Sections 79.12–79.18), this rule organizes existing sections 79.1–79.11 into Subparts A (Administrative Provisions), B (Archeological Collections Management), C (Public Access to and Use of Collections), and D (Inspections and Inventories of Collections). This rule also revises sections 79.1–79.4 to update legal citations, removes paragraph designations for defined terms in section 79.4 as recommended by the Office of the Federal Register's Document Drafting Handbook, and adds two defined terms that are used in Subpart E. A section-by-section analysis of the rule can be found in the Background section of the proposed rule.

Summary of Public Comments

The NPS published a proposed rule in the **Federal Register** on November 18, 2014 (79 FR 68640). The NPS accepted comments on the proposed rule through the mail, hand delivery, and through the Federal eRulemaking Portal at *http://www.regulations.gov.* Comments were accepted through February 17, 2015. The NPS received comments from individuals, federally recognized tribes, state and local government agencies, public institutions, and professional organizations. Summaries of the issues raised in the comments and responses from the NPS are provided below.

Disposition Process

1. Comment: Several commenters addressed the notification and consultation requirements in the

proposed rule. Commenters requested more time be given to interested parties to comment on a proposed disposition, and that additional direct notice be given to interested parties during the disposition process. Commenters asked that the Federal Agency Official (FAO) take additional steps to engage with public stakeholders during the disposition process.

NPS Response: The NPS made several changes in the final rule to ensure there is sufficient notice provided to interested parties during the disposition process. The NPS added a requirement that the FAO provide at least 60 days for notified entities to comment on a proposed disposition. The NPS increased the time allowed for objecting to a final determination of disposition from 30 to 60 days. The NPS added to the list of parties who must receive notice of proposed dispositions by including state archeologists, certain private landowners, broader categories of Indian tribes with cultural relationships to material remains in the collections, and organizations and institutions for which the agency has an existing relationship for research, excavation, curation, education, or other partnership in the state and region from which the material remains to be disposed were recovered. The NPS believes these notice requirements will sufficiently involve the relevant stakeholders in the disposition process prior to any determination of disposition published in the **Federal Register**.

2. Comment: Two commenters recommended that the rule limit the amount of time given to the FAO to choose a method of disposition.

NPS Response: The NPS declines to adopt this recommendation because it is important to preserve flexibility in this part of the disposition process, so that the most appropriate method is chosen. Time limits are required in other phases of the process such as during the periods for commenting on and objecting to determinations of disposition. A time limit at this stage would not further the purpose of the rule because agencies could be motivated to forego considered deliberation in order to select a method of disposition merely to meet a time limit.

3. Comment: One commenter argued that judgements other than those of the Indian Claims Court, as well as other types of documentation, should be allowed to determine aboriginal occupancy of land for purposes of whether an Indian tribe may receive deaccessioned materials excavated from lands other than Indian lands. Another commenter argued that culturally affiliated tribes that request deaccessioned material remains should be allowed to receive them.

NPS Response: The NPS has added two methods of disposition in paragraph 79.13(b) to accommodate these requests. Aboriginal occupation of lands where material remains were removed can now be documented by any type of evidence. The final rule allows material remains to be conveyed to federally recognized Indian tribes for the purposes of traditional, cultural, educational, or religious practices.

4. Comment: One commenter asked whether deaccessioned materials could be reused for educational or interpretive purposes (*i.e.,* adaptive reuse).

NPS Response: Deaccessioned materials may be used for educational or interpretive purposes. The methods of disposition in section 79.13 allow for such reuse. The rule is therefore sufficiently flexible to allow adaptive reuse after material remains have been deaccessioned.

5. Comment: One commenter argued that all methods of disposition are unacceptable because disposition is not a preservation activity.

NPS Response: ARPA section 5 (16 U.S.C. 470dd) specifically authorizes the Secretary of the Interior to promulgate regulations providing for the ultimate disposition of archeological resources. A requirement for specific disposition methods to constitute a preservation activity has no basis in the statutory authority.

6. Comment: Two commenters requested that the NPS list the methods of disposition in priority order for material remains excavated from public lands. One commenter requested that the rule provide a clear step-by-step process.

NPS Response: The NPS declines to impose a priority order on the methods of disposition because this would unduly restrict the discretion given to FAOs to dispose of deaccessioned material remains in the manner most appropriate to the situation. With the goal of making the disposition process as clear as possible, the NPS has provided a step-by-step process for an FAO to follow.

Federal Agency Official (FAO)

7. Comment: One commenter asked the NPS to identify the level of government where the FAO is located.

NPS Response: The FAO is defined in section 79.4 to mean ''any officer, employee or agent officially representing the secretary of the department or the head of any other agency or instrumentality of the United States having primary management authority over a collection that is subject to this part.'' In practice, the FAO is typically situated at the departmental, national, headquarters, or equivalent level of the agency, unless the agency has a different policy.

Collections Advisory Committee

8. Comment: Several commenters asked that individuals from outside of the Federal government be invited to participate on the collections advisory committee. One commenter proposed that any disposition should be contingent on a consensus recommendation from the collections advisory committee. Another commenter suggested that the DCA should not be eligible to serve on a collections advisory committee. Several commenters recommended that qualified experts be given more influence on the committee, while one commenter argued that the collections advisory committee should be made up of individuals who are professionally disinterested or distanced from the material remains being considered for disposition.

NPS Response: The NPS has revised the rule to clarify the qualifications necessary to serve on a collections advisory committee. The NPS added a requirement that the committee make consensus recommendations to the FAO about proposed dispositions. The NPS also added a provision stating that the DCA may not participate on the committee, because the DCA may be called upon to make recommendations in the case of a dispute. With the exception of certain Tribal officials specified in paragraph 79.15(e)(3), the NPS declines to delegate the responsibilities of Federal agencies for federally owned or administered property to non-Federal employees through an expansion of the composition of the committee. In order to increase the transparency of the committee, the final rule requires the collections advisory committee to prepare a written report for the FAO that contains, at a minimum, the following:

- The information required for the **Federal Register** notice of determination of disposition identified in paragraphs (i)(1)(i) through (iii) of section 79.15;
- The membership of the committee and their role and expertise pertinent to the deliberations;
- The committee's recommendations, including any conditions of transfer or conveyance; and
- An explanation of why the committee determined other methods of disposition were of lesser public benefit.

9. Comment: Several commenters asked the NPS to include specific procedures in the rule that collections advisory committee members must follow in order to make recommendations to the FAO about proposed dispositions, rather than allowing the committee to determine their own rules. One commenter recommended that the committee have clearly written procedures, including timelines and opportunities for public consultation and input. Another argued that the rule should identify the specific tasks and procedures of the collections advisory committee. One commenter proposed that the regulations establish a single committee to review every proposed disposition.

NPS Response: The rule supports the need for flexibility in the disposition process, including in the formation and operation of collection advisory committees. The NPS believes these committees must address the unique circumstances of each proposed disposition, as well as reflect the unique needs, capacities, and operating environments of the responsible Federal agencies, which a single central committee could not do. However, the rule also establishes some basic requirements about the composition and operation of the committees to enable appropriate recommendations. In order to strike a balance between fostering flexibility and imposing standard requirements, the rule establishes qualifications for committee membership and requires written procedures to be approved by the FAO. The NPS believes this is sufficient to ensure all recommendations are fair, open, timely, and in the best interest of the public. Mandating specific rules of procedure for each committee would be unduly rigid and make the work of the committees more difficult because they would be forced to apply strict rules to the unique situations and capacities of each committee. Although the regulations require that the composition of the committees be tailored to the characteristics of each disposition, nothing in the regulations prevents the same committee from reviewing more than one disposition of a similar nature. Under these circumstances, the Federal agency would not need to form a new committee for each proposed disposition provided the members of the committee meet the requirements in the regulations with respect to the particular collection under review.

Insufficient Archeological Interest

10. Comment: One commenter argued that a determination of insufficient archeological interest should be made on the basis of independent peer review that includes experts outside of the Federal government.

NPS Response: The NPS added a requirement in the final rule that the FAO must consult with qualified museum professionals at non-Federal repositories about the appropriateness of a proposed disposal. The NPS acknowledges that the perspective of qualified museum professionals responsible for the care and curation of the subject materials is necessary for the FAO to make an informed determination. FAOs must use appropriate judgment and base determinations of disposition on appropriate supporting information. Because the rule regulates federally owned or administered collections, however, it remains appropriate that Federal agency staff and officials, with verifiable knowledge of the materials, make decisions regarding the disposition of material remains in those collections.

11. Comment: One commenter argued that a lack of original records should not be sufficient to presume a determination of insufficient archeological interest if provenience can be reconstructed through other means.

NPS Response: The loss or destruction of associated records is one factor in determining whether there is a lack of provenience information. Under section 79.12, a qualified archeological or museum professional must determine that a disposition will not negatively impact the overall value of the collection in order to make a finding of insufficient archeological interest. In doing so, the professional must make a concerted effort to research all records, including museum records, associated with a collection. In addition, the FAO must determine that disposition of the material remains will not negatively impact the overall integrity of the original collection.

12. Comment: One commenter stated that it is unclear who makes the determination of insufficient archeological interest and what that individual's qualifications should be.

NPS Response: At least one qualified archeological or museum professional with verifiable knowledge of and experience in the type of material remains being evaluated makes a determination of insufficient archeological interest. The FAO determines whether the professional is qualified, using the Professional Qualification Standards set by the Secretary of the Interior as a benchmark, and considering the professional's verifiable knowledge of the material remains. The FAO then determines, under section 79.15, whether the material remains are eligible for disposition under this subpart.

13. Comment: Two commenters requested that the rule define the following terms related to insufficient archeological interest: Material remains, physical integrity, irreparable damage, overly abundant, and representative sample.

NPS Response: Existing regulations define material remains as ''artifacts, objects, specimens and other physical evidence that are excavated or removed in connection with efforts to locate, evaluate, document, study, preserve or recover a prehistoric or historic resource.'' This definition goes on to provide illustrative examples of different classes of material remains. The NPS declines to define the other terms requested by the commenters. These terms are commonly used by the archeological community and must be applied in context using the professional judgement of qualified personnel. For example, the amount sampled and sampling method for a representative sample must be determined on a case-by-case basis, using the professional discretion of subject matter experts and best available information. The rule requires subject matter experts to have verifiable knowledge of the material remains to be examined.

14. Comment: One commenter questioned whether material remains could possess increasing archeological interest over time.

NPS Response: For material remains that are overly redundant and not useful for research, the rule requires that a sampling strategy be developed and implemented in order that the retained samples may be subjected to new or improved analytical technologies in the future that could demonstrate those materials remains have greater archeological interest than previously known. The NPS has revised the rule to clarify that samples of material remains determined to be overly redundant and not useful for research must be representative of the population as a whole from which the sample was taken. This will help ensure the integrity and potential future worth of samples that are retained.

15. Comment: One commenter suggested that the criterion ''overly redundant and not useful for research'' be split into two separate criteria, each of which could support a determination of insufficient archeological interest.

NPS Response: The NPS declines to split this criterion into separate criteria because both elements of this criterion are necessary to establish insufficient

archeological interest. Fulfilling only one of these two elements (overly redundant or not useful for research) could not result in a determination of insufficient archeological interest. A redundant set of material remains that is still useful for research could have sufficient archeological interest. For instance, two sets of similar material remains derived from different archeological contexts are likely, by virtue of their spatial disparity, to provide some information about the past, even though those material remains may seem similar or identical in a museum setting. Alternatively, material remains not useful for research but not overly redundant could still have archeological interest because: (1) Their uniqueness may render them inherently informative about the past and (2) they may become useful for research in the future as new technologies are developed. Thus, to meet this test, material remains must be both overly redundant and not useful for research.

16. Comment: One commenter suggested that the NPS establish a hierarchy of levels of archeological interest and provide a range of disposition options for each level.

NPS Response: The rule only addresses the ultimate disposition of certain materials that have insufficient archeological interest. Identifying different degrees or levels of insufficient archeological interest and assigning different disposal options for each level would unnecessarily complicate the process.

Costs

17. Comment: Several commenters addressed the costs for Federal agencies and recipient entities of complying with the disposition process under the rule. Several commenters were concerned that the rule would place financial strain on repositories for retaining materials during the disposition process without addressing a general shortfall of personnel and funding. One commenter expressed concern that several methods of disposition (*e.g.,* conveyance to suitable repositories or institutions) would impose unfair financial burdens on recipients of deaccessioned material remains.

NPS Response: The rule will impose little or no direct cost upon the public. Section 79.7 makes Federal agencies responsible for funding the curation of material remains. This includes costs associated with deaccessioning material remains in federally owned or administered collections, including costs borne by repositories that retain materials during the disposition process. Federal agencies must accession and catalog material remains before deaccessioning, and must follow relevant law and agency policy in ensuring that funding decisions address all aspects of collection stewardship, not just deaccessioning. The rule provides a series of options for disposition and does not require any group or individual to accept material remains that are eligible for disposal. The rule does not impose unfair financial burdens on recipients of deaccessioned material remains because those recipients are under no obligation to accept the material remains. A recipient must independently choose to accept deaccessioned material, thus it will have an opportunity in advance to consider the financial impact of its participation in the disposition process. The NPS believes the disposition process in the rule is financially achievable for Federal agencies.

18. Comment: Two commenters inquired about the costs of deaccessioning material remains of insufficient archeological interest. They were concerned that resources, which could be used to catalog and curate collections, might be diverted to deaccessioning instead.

NPS Response: To limit the possibility that Federal agencies allocate resources to deaccessioning rather than to curating collections, the rule provides controls, under section 79.12, on the disposition process, intended to limit its use only to appropriate circumstances. Deaccessioning is one part of a comprehensive curation methodology. In order to be eligible for disposition, material remains must be part of a Federal collection, and thus have undergone appropriate intake and accessioning procedures, which must be documented in accordance with agency protocols. Agency staff responsible for determining whether particular material remains lack archeological interest must consider the relationship of the material remains to the collection as a whole. Any effort to determine the archeological interest of material remains must include a review of the overall collection, along with associated documentation, from which those material remains are derived. For these reasons, the NPS does not believe that the disposition process will divert funds from curation because deaccessioning is part of a responsible curation program.

19. Comment: One commenter suggested that the disposition process will impose new costs for excavation because allowing for disposition will force archeologists to perform a more thorough analysis of material remains prior to curating them in a repository.

NPS Response: The NPS does not consider this scenario as likely to occur. However, a more thorough analysis of collections during an initial excavation project could be a desirable outcome because it means that the documentation concerning material remains will provide a better understanding of the archeological interest and improve the value of the resulting curated collections to the public. Any increase in the initial cost of analysis would be voluntary.

Compliance

20. Comment: Several commenters discussed ways that implementation of the rule will support and interplay with compliance regimes for laws such as the NHPA and the National Environmental Policy Act (NEPA).

NPS Response: Under section 106 of the NHPA, Federal agencies must consider the effect of an undertaking on any historic property that is included in or eligible for inclusion in the National Register. Museum collections, including archeology collections, are not generally considered historic properties (see National Register Bulletin 15). Further, material remains determined to be of insufficient archeological interest are not likely to be included in or eligible for inclusion in the National Register because, characteristically, they would not be worthy of preservation. NEPA requires Federal agencies to fully consider the impacts of proposals that would affect the human environment prior to deciding to take an action. The disposal of material remains under this rule will generally not constitute a Federal action under NEPA that would have a significant effect on the human environment. Nevertheless, FAOs must consider the context related to each proposed disposal of material remains and comply with all applicable laws, including the NHPA and NEPA, before making a final determination. The FAO must consider the opinions, as appropriate, of the collections advisory committee, Indian Tribes, and other available experts in making disposition decisions to ensure compliance with Federal law. In cases where collections are held under a compliance agreement, such as a Memorandum of Agreement under section 106 of NHPA, the FAO must consider the context and the terms of the agreement to determine whether disposal is appropriate.

Administrative Record

21. Comment: Several commenters focused on the creation and preservation of the administrative record of the disposition process. One commenter asked that the

administrative record be provided to tribes and SHPOs, particularly when they possess additional data about the site or collection. Other commenters asked the NPS to clarify the requirement in paragraph 79.15(i)(2)(i) to prepare a detailed list of material remains to be deaccessioned and better define when photographic documentation would be considered appropriate.

NPS Response: Section 79.18 requires Federal agencies to include in their administrative record specific documentation of the determination of disposition. Consistent with these requirements, Federal agencies should follow their own procedures for preparing, preserving, and distributing administrative records. The FAO should follow existing practices that comply with applicable state and Federal standards for recording material remains in archeological collections when preparing the detailed list of material remains required by paragraph 79.15(i)(2)(i). This paragraph specifies that the list must include a description of each object, or lot of objects if there are multiples of a particular type, and photograph(s) of the objects when appropriate. The FAO should also consider standard practices to determine when photographic documentation is appropriate.

Authority and Applicability of Regulations

22. Comment: Two commenters questioned whether the authorities cited in section 79.2 authorize the NPS to allow the disposition of material remains. Two commenters questioned the applicability of the rule to material remains excavated under the Antiquities Act and the interplay with prior regulations.

NPS Response: Section 5 of ARPA (16 U.S.C. 470dd) gives the Secretary the explicit and sole authority to promulgate regulations providing for ''the ultimate disposition'' of ARPA archeological resources and other resources removed pursuant to the Antiquities Act and the RSA. These authorities are cited in paragraph 79.2(b)(2) which, except for updated citations, is not changed by this rule. The explicit statutory authority to promulgate this rule supersedes any preceding regulatory requirements regarding similar subject matter, in particular, 43 CFR 3.17. This more recent statutory authority thus makes it appropriate to include those resources excavated under the Antiquities Act and eligible for disposal via the process described in the new Subpart E as subject to this rule. For clarity, this rule adds a note to 43 CFR 3.17 stating that resources excavated under the Antiquities Act are eligible for disposal via Subpart E of 36 CFR 79.

23. Comment: Several commenters requested clarification about the term ''practical management authority'' and the meaning of ''indirect'' practical management authority.

NPS Response: Part 79 applies to federally owned or administered collections. Section 79.3(a) uses the term ''practical management authority'' to further explain the circumstances under which collections that are owned by the United States are subject to Part 79. Federal agencies have ownership of collections due to specific laws, activities on Federal lands, or other circumstances, and these collections are managed in a variety of ways. In order for those collections to be subject to Part 79, a Federal agency that owns a collection also must have ''practical management authority'' over that collection, either directly or indirectly. Otherwise, Federal agencies would be responsible for curating collections that they do not control. Direct practical management authority generally includes situations where a Federal agency is directly administering collections at Federal facilities. Indirect practical management authority includes situations in which a Federal agency has legal responsibility and control over collections but a non-Federal entity has responsibility for curating the collection. This is usually documented through the terms of an agreement, contract, permit, or authorized expenditures.

24. Comment: One commenter stated that the rule should only apply to federally owned collections and that there should be no question about who has legal title over material remains that are proposed for disposal.

NPS Response: The FAO should be able to discern the ownership of material remains when determining if those remains are eligible for disposal under paragraph 79.12(a) and when reviewing the provenience information to determine if those remains have insufficient archeological interest under paragraph 79.12(e)(2)(i). Directions from ascertainable owners or questions regarding ownership must inform the FAO's proposed disposition determination. Clear legal ownership by the United States is not a prerequisite for disposal of material remains under Part 79; the rule also applies to material remains that are not owned by the United States but that are managed or controlled by a Federal agency pursuant to the Antiquities Act, NHPA, RSA and ARPA. Other provisions of the rule explicitly ensure that certain owners of federally administered collections, such as Indian individuals or tribes under 79.13(a), have an opportunity to receive them or to object to a proposed disposition. This aspect of the rule is intended to ensure that the government cares for archeological collections in its possession in accordance with applicable laws.

25. Comment: Based on established practices that allow for the re-interment of human remains not subject to NAGPRA, several commenters suggested that this rule should apply to human remains not subject to NAGPRA and identify reburial as a method of disposition. One commenter suggested that the rule establish a disposition process for human remains that are not subject to NAGPRA.

NPS Response: During consultation for the proposed rule, Federal agencies, Tribes, and professional organizations suggested that excluding all human remains from the disposition process for materials of insufficient archeological interest described in this subpart would simplify the rule and avoid confusion with NAGPRA and its implementing regulations. As a result, the proposed rule excluded all human remains from disposition and, in doing so, did not distinguish between human remains subject to NAGPRA and other human remains. The final rule clarifies in paragraph 7.12(b)(1) that Native American cultural items under NAGPRA, which can include human remains, are not eligible for disposition under this rule. Native American human remains are subject to disposition or repatriation under NAGPRA. In paragraph 7.12(b)(2), the final rule also states that other human remains not subject to NAGPRA are ineligible for disposition under Subpart E. The NPS does not intend for this subpart to affect established practices that otherwise allow for the disposition and re-interment of human remains not subject to NAGPRA. The final rule clarifies that human remains not subject to NAGPRA are excluded only from the process described in Subpart E. The NPS is reserving section 79.14 to address this issue in the future if necessary.

Disputes

26. Comment: Several commenters addressed the procedures for objecting to determinations of disposition. One commenter asked that the public have 90 days to dispute a determination of disposition, and that the requirement for submission of documentation be removed. Another commenter recommended that those objecting to a disposition should be responsible for finding a new repository. One

commenter suggested that the DCA should make binding decisions for all objections instead of non-binding recommendations to the FAO. Another commenter requested that the rule require the DCA to thoroughly explain their recommendation to the FAO. Two commenters asked that the rule include a dispute resolution process in section 79.16 to help resolve disagreements over which tribes should receive material remains that have been determined to be eligible for disposal. One commenter specifically recommended adopting the dispute resolution language from NAGPRA.

NPS Response: The NPS made several changes in section 79.16 of the final rule to provide a more effective and inclusive process for objecting to a determination of disposition. The NPS lengthened the timeframe to object to a determination of disposition from 30 to 60 days. The NPS believes this will provide sufficient time for interested parties to file an objection, in part because the list of those notified and consulted with prior to the determination of disposition is comprehensive. It is important that the objecting party document the reasons for the objection so that the DCA and the FAO are able to evaluate the merits of the objection. While objecting parties may suggest a different repository, they are not required to as a condition to filing an objection. The NPS also shortened the timeframe for the FAO to respond to the DCA's non-binding recommendation from 60 to 30 days and added a requirement that the DCA forward a copy of the objection to the FAO within 5 days of receipt of the objection. The final rule also requires the DCA to consult with the objecting party and the FAO with the aim of resolving the objection. This will ensure that the DCA plays a significant role in the resolution of disputes over determinations of disposition. The final rule requires that the DCA explain their recommendation to the FAO.

The NPS declines to make the DCA's decision binding because the DCA's role to other government agencies is advisory in nature. The DCA has no authority to broker binding arbitration with other Federal agencies, nor does the DCA have the authority to make decisions on their behalf. Similarly, the NPS declines to outline a dispute resolution process specifically for tribes because such a process would be duplicative of the appeal process in section 79.16. In addition, the NPS notes that the dispute resolution process in NAGPRA is specifically authorized in 25 U.S.C. 3006(c); no such authorization exists in ARPA or the other applicable authorities for this rule.

Rulemaking Process

27. Comment: Several commenters stated that the rulemaking process was inadequate because of insufficient opportunities for public comment. One commenter asked for an extension of the public comment period.

NPS Response: The NPS consulted widely with Tribes and interest groups before publishing the proposed rule. The proposed rule was open for public comment for 90 days, from November 18, 2014, through February 17, 2015. This is 30 days longer that the standard comment period of 60 days that is identified in Department of the Interior Policy (318 Departmental Manual, section 5.3). The NPS received a substantial number of comments and has worked to address or respond to all issues raised by those comments in this final rule.

Impacts to Federal Collections

28. Comment: Two commenters stated that many collections were made with the understanding that they would be held in perpetuity by the government for future study, and that perpetual curation might be required by agreements entered into for purposes of complying with section 106 of the NHPA.

NPS Response: Legal instruments for the curation of materials, including those created under the section 106 consultation process, such as memoranda of agreement or programmatic agreements, may contain provisions requiring curation of materials beyond what otherwise would be required by this rule. When considering the potential disposal of materials covered by any such agreement, the FAO must review the terms of the agreement to determine whether the agreement and section 79.12 can be reconciled to allow disposal. Legally binding requirements for the perpetual curation of materials that appear in an agreement or other written instrument will not be affected by the disposition process established in this rule.

29. Comment: One commenter argued that deaccessioning would greatly reduce the volume of material remains available for study, which would lead to increased excavation.

NPS Response: The disposition process established in this rule applies narrowly to material remains of insufficient archeological interest. The rule does not compel the wholesale divestment by the government of its collections, but instead allows for small reductions in the size of some collections under specific circumstances. Samples of material remains to be deaccessioned under this rule must be retained when those materials are deemed overly redundant and not useful for research. The cautious approach to disposition required by this rule makes it unlikely that the rule will result in a steep reduction in the amount of materials available for study in Federal collections, and a consequential need for additional excavations.

NAGPRA Consultation

30. Comment: Two commenters sought stronger requirements to consult with Tribes regarding the determination that material remains are not subject to NAGPRA. One commenter asked the NPS to clarify the FAO's responsibilities to consider NAGPRA compliance.

NPS Response: Federal agencies have separate procedural requirements under NAGPRA to ensure that NAGPRA cultural items in their collections are included in inventories and summaries. Extensive consultation is required during the inventory and summary process under 43 CFR 10.8 and 10.9. In general, Federal agencies were required to complete their NAGPRA summaries by November 16, 1993, and their NAGPRA inventories by November 16, 1995, so, in most cases, Federal agencies will have already determined which items in their collections are NAGPRA cultural items. Section 79.12 provides an additional measure to ensure NAGPRA cultural items are handled pursuant to NAGPRA and not subject to disposition under this rule. Prior to making a final determination of disposition, the FAO must determine that the material remains are not NAGPRA cultural items. The rule further states that, when Native American material remains are proposed for disposition, the collections advisory committee must include one or more elected officers (or their designees) of federally recognized Indian Tribes that are regularly consulted by the Federal agency. The rule also contains robust notification requirements that will help ensure that interested Tribes are aware of proposed dispositions. Further, any Tribe may object to determinations of disposition if it believes the materials are NAGPRA cultural items. The NPS believes that these requirements are sufficient to ensure that Native American cultural items subject to NAGPRA will not be disposed of under this rule.

Use of Deaccessioned Material Remains

31. Comment: One commenter argued that enforcing the restrictions on disposition of material remains in the proposed rule would constitute a taking of property under the Fifth Amendment of the Constitution, specifically for material remains excavated and removed from Indian lands and returned to the Indian individual or Indian tribe having rights of ownership over the resources. Commenters sought to ensure that deaccessioned material remains may not be sold in the future. Another commenter questioned the ability of the FAO to enforce prohibitions on government employees receiving deaccessioned material remains.

NPS Response: The NPS has clarified in paragraph 79.13(b) that, as a condition of disposal, the FAO will reasonably ensure that material remains from public lands that are not Indian lands may not be traded, sold, bought, or bartered after disposal is completed. This condition will not apply to material remains from Indian lands. The NPS has removed the prohibition on government employees receiving deaccessioned material remains because it is redundant with government-wide ethics requirements that address the concerns originally underlying this proposed restriction. Indian individuals who are also Federal employees must work with their agency's ethics officials to determine a course of action in the event that they wish to receive deaccessioned material remains.

General Support and Opposition

32. Comment: Some commenters expressed general support for the rule, praising its clear language and stringent and rigorous disposition process. Commenters recognized the need for the rule and its potential to improve the value of collections and reduce careless accession of material remains. Other commenters expressed general opposition to the rule, citing their belief that material remains should not be deaccessioned and that the rule will not provide a complete solution to the curation crisis.

NPS Response: Responsible deaccessioning is a necessary tool for maintaining the scientific value of collections. Several Federal agencies requested this rule, which supports the proper curation of Federal collections. This rule establishes a rigorous and deliberative disposition process that, when properly implemented, will prevent the careless deaccessioning of material remains. Supporting agency stewardship of archeological collections is the foundational goal of 36 CFR 79.

Changes in the Final Rule

After considering the public comments and after additional review, the NPS made the following substantive changes in the final rule. The NPS made other non-substantive, editorial changes for clarity and ease of reading. In many places, the NPS replaced outdated citations to Title 16 of the U.S. Code with correct citations to Title 54. The NPS also removed the paragraph designations in section 79.4 and organized the defined terms alphabetically, as recommended in the Office of the Federal Register's Document Drafting Handbook. In order to make these changes, the entire section 79.4 appears below in the regulatory text even though the only changes to that section are to add definitions of ''Departmental Consulting Archeologist'' and ''provenience information.''

Final rule section or paragraph	Change	Reason for change
79.4	Added definitions of the terms ''Departmental Consulting Archeologist'' and ''provenience information''.	Clarifies the meaning of these terms for non-specialists.
79.12(b)(2)	Specified that the term ''human remains'' refers to human remains that are not ''cultural items'' under NAGPRA.	Clarifies that no human remains may be disposed of under this rule, whether or not they are subject to NAGPRA.
79.12(c)	Clarified that only persons who meet the applicable Professional Qualification Standards set by the Secretary may propose the disposal of material remains.	Helps ensure that only qualified experts may initiate the disposition process. Ensures that disposition is not undertaken casually or as a matter of convenience. The professional standards are available here: *https://www.nps.gov/articles/sec-standards-prof-quals.htm.*
79.12(c)(1)	Added a requirement that Federal agency staff members must have verifiable knowledge of the particular material remains that are proposed for disposal.	Helps ensure that disposition is not undertaken improperly because qualified experts were not involved.
79.12(e)	Added a requirement that archeological or museum professionals must have verifiable knowledge of the particular material remains in order to determine whether those material remains have insufficient archeological interest.	Helps ensure that disposition is not undertaken improperly because qualified experts were not involved.
79.12(e)(2)(i)(C)	Clarified that a lack of provenience information may be established if associated records never existed, have been lost, or have been destroyed.	Addresses a legitimate circumstance where there is no existing provenience information.
79.12(e)(2)(iii)	Clarified that representative samples of material remains that are overly redundant and not useful for research must be representative of the population as a whole from which the sample was taken.	Helps ensure that a statistically valid sample is retained in the event that new analytical techniques are developed that allow the sample to generate useful information about the past.
79.13(a)(2)	Clarified that the FAO must receive written consent and relinquishment of ownership from the Indian individual or tribe having rights of ownership before otherwise disposing of material remains excavated from Indian lands.	Helps ensure that the FAO will not dispose of material remains owned by Indian individuals or tribes without their consent.
79.13(b)(5)	Added the following method of disposal for material remains excavated or removed from public lands: Convey to a federally recognized Indian tribe for the purpose of traditional cultural, educational, or religious practices.	Responds to public comment and improves consistency between the acceptable methods of disposition for materials removed from Indian and public lands.

Final rule section or paragraph	Change	Reason for change
79.15(d)	Added a requirement that the FAO consult with qualified museum professionals located in the repository that provides curatorial services for material remains proposed for disposal when those museum professionals did not propose the disposal.	Helps ensure that appropriate experts are involved in the disposition process.
79.15(e)	Added a requirement that the collections advisory committee make consensus recommendations to the FAO about proposed dispositions.	Responds to public comment and helps ensure that disposition is not undertaken lightly or improperly.
79.15(e)(1)	Added a provision stating that the DCA may not participate on a collections advisory committee.	Helps maintain the impartiality of the DCA, who serves as the arbiter of disputes about proposed dispositions.
79.15(e)(3)	Clarified that the requirement that collections advisory committees include at least one representative of an Indian tribe only applies if there are Native American material remains proposed for disposal.	Ensures the appropriate inclusion of tribal viewpoints in considering a disposition of Native American material remains.
79.15(e)(5)	Added a requirement that the collections advisory committee submit a written report to the FAO about any proposed disposition.	Responds to public comments and improves the administrative record of a disposition.
79.15(g)	Added a requirement that, for material remains excavated from Indian land, the FAO provide a copy of the associated records to the appropriate Tribal Historic Preservation Officer or tribal official.	Responds to public comments and improves accountability to tribal governments.
79.15(h)	Added a minimum duration of 60 days for the public comment period for a proposed disposition. Made the FAO responsible for responding only to relevant, substantive comments.	Responds to public comments to improve timeliness and public accountability. Reduces the administrative burden on the FAO during the comment review period.
79.15(h)(1)	Added a requirement that the FAO must give notice of proposed dispositions to the State Archeologist if there is one.	Improves coordination with state officials and improves the administrative record.
79.15(h)(3)	Added a requirement that the FAO must give notice of proposed dispositions to private landowners from whose lands the objects to be disposed were removed.	Responds to public comments to provide additional information to landowners.
79.15(h)(5)	Removed the requirement that the FAO must give notice to organizations and institutions with an active department of or program in archeology or anthropology pertaining to the archeology of the state or region from which the material remains to be disposed of were recovered. Clarified that the FAO must give notice of proposed dispositions to organizations and institutions for which the agency has an existing relationship pursuant to a written instrument (*e.g.,* permit, agreement) for research, excavation, curation, education, or other partnership in the state and region from which the objects to be disposed were recovered.	Removes ambiguity about which institutions and organizations must receive notice of proposed dispositions. Reduces the burden of compliance for the FAO by requiring only notification of those entities that have a formal relationship. Improves communication about proposed disposition actions with interested researchers.
79.16	Lengthened the timeframe to object to a determination of disposition from 30 to 60 days after publication of the notice of determination of disposition in the **Federal Register**.	Responds to public comments and provides more opportunity for the public to object to a proposed disposition.
79.16(a)	Added a requirement that the DCA forward a copy of objections to the FAO within 5 days of receipt.	Improves accountability from the DCA to the FAO and streamlines the objection process.
79.16(c)	Added a requirement that the DCA consult with the objecting party and the FAO with the aim of resolving the objection.	Responds to public comments to improve the fairness of the objection process by providing another opportunity for discussion between the objecting party and the FAO.
79.16(d)	Added a requirement that the DCA must thoroughly explain their non- binding recommendation to the FAO.	Responds to public comment to provide a more effective and inclusive disputes process.
79.16(e)	Shortened the timeframe for the FAO to respond to the DCA and the objector with a final determination from 60 to 30 days.	Streamlines the objection process and encourages timely resolution to objections.
79.16(f)	Clarified that notice of a decision on an objection is a final agency action under the Administrative Procedure Act.	Responds to public comment to make procedures clear to the public.
79.17	Added a requirement that disposition after an objection will occur no sooner than 30 days after the FAO publishes the notice of decision on the objection and any amendments in the **Federal Register**.	Responds to public comment to make procedures clear to the public.
43 CFR 3.17	Added a note that resources excavated under the Antiquities Act may be eligible for disposal under Subpart E of 36 CFR 79.	Responds to public comments questioning the applicability of the rule to material remains excavated under the Antiquities Act.

Compliance With Other Laws, Executive Orders and Department Policy. Regulatory Planning and Review (Executive Orders 12866 and 13563)

Executive Order 12866 provides that the Office of Information and Regulatory Affairs (OIRA) in the Office of Management and Budget will review all significant rules. OIRA has determined that this rule is not significant.

Executive Order 13563 reaffirms the principles of Executive Order 12866 while calling for improvements in the nation's regulatory system to promote predictability, to reduce uncertainty, and to use the best, most innovative, and least burdensome tools for achieving regulatory ends. Executive Order 13563 directs agencies to consider regulatory approaches that reduce burdens and maintain flexibility and freedom of choice for the public where these approaches are relevant, feasible, and consistent with regulatory objectives. Executive Order 13563 emphasizes further that regulations must be based on the best available science and that the rulemaking process must allow for public participation and an open exchange of ideas. The NPS has developed this rule in a manner consistent with these requirements.

Regulatory Flexibility Act

This rule will not have a significant economic effect on a substantial number of small entities under the Regulatory Flexibility Act (5 U.S.C. 601 *et seq.*). This certification is based on information contained in the economic analyses found in the report entitled ''Cost-Benefit and Regulatory Flexibility Analyses: Proposed Regulations on the Curation of Federally-Owned or Administered Archeological Collections'' that is available online at the following URL: *https://www.nps.gov/orgs/1187/upload/Regulatory_Analyses_36_CFR_Part_79_12.pdf.*

Congressional Review Act (CRA)

This rule is not a major rule under 5 U.S.C. 804(2), the CRA. This rule:

(a) Does not have an annual effect on the economy of $100 million or more.

(b) Will not cause a major increase in costs or prices for consumers, individual industries, Federal, state, or local government agencies, or geographic regions.

(c) Does not have significant adverse effects on competition, employment, investment, productivity, innovation, or the ability of U.S.-based enterprises to compete with foreign-based enterprises.

The rule relates to internal administrative procedures and management of government function. It does not regulate external entities, impose any costs on them, or eliminate any procedures or functions that would result in a loss of employment or income on the part of the private sector.

Unfunded Mandates Reform Act

This rule does not impose an unfunded mandate on state, local, or tribal governments or the private sector of more than $100 million per year. This rule does not have a significant or unique effect on state, local or tribal governments, or the private sector. A statement containing the information required by the Unfunded Mandates Reform Act (2 U.S.C. 1531 *et seq.*) is not required.

Takings (Executive Order 12630)

This rule does not affect a taking of private property or otherwise have taking implications under Executive Order 12630. A takings implication assessment is not required.

Federalism (Executive Order 13132)

Under the criteria in section 1 of Executive Order 13132, this rule does not have sufficient federalism implications to warrant the preparation of a federalism summary impact statement. This rule does not regulate, change, or otherwise affect the relationship between Federal and state governments. A federalism summary impact statement is not required.

Civil Justice Reform (Executive Order 12988)

This rule complies with the requirements of Executive Order 12988. Specifically, this rule:

(a) Meets the criteria of section 3(a) requiring that all regulations be reviewed to eliminate errors and ambiguity and be written to minimize litigation; and

(b) Meets the criteria of section 3(b)(2) requiring that all regulations be written in clear language and contain clear legal standards.

Paperwork Reduction Act (44 U.S.C. 3501 *et seq.*)

This rule does not contain information collection requirements, and a submission to the Office of Management and Budget under the Paperwork Reduction Act is not required. The NPS may not conduct or sponsor and you are not required to respond to a collection of information unless it displays a currently valid OMB control number.

National Environmental Policy Act

This rule does not constitute a major Federal action significantly affecting the quality of the human environment. A detailed statement under the NEPA is not required because this rule is covered by a categorical exclusion. This rule is excluded from the requirement to prepare a detailed statement because it qualifies as a regulation of an administrative and procedural nature. (For further information see 43 CFR 46.210(i)). This rule does not involve any of the extraordinary circumstances listed in 43 CFR 46.215 that would require further analysis under NEPA.

Federal Advisory Committee Act

Intergovernmental consultation recommended under this rule is exempt from the Federal Advisory Committee Act (FACA). This rule requires that consultation with Indian tribes be conducted between Federal officials and elected tribal officers or their designated employees acting in their official capacities, who meet solely for the purpose of exchanging views, information, or advice related to the management or implementation of this rule. Consultation with Tribes under this rule thus meets the two-part test for an exemption from the FACA set out in the Unfunded Mandates Reform Act of 1995, Public Law 104–4.

Consultation With Indian Tribes (E.O. 13175 and Departmental Policy)

The Department of the Interior strives to strengthen its government-to-government relationship with Indian Tribes through a commitment to consult with Indian Tribes and recognition of their right to self-governance and tribal sovereignty. The NPS has evaluated this rule under the criteria in Executive Order 13175 and under the Department's tribal consultation policy and has determined that tribal consultation is not required because the rule will have no substantial direct effect on federally recognized Indian tribes. Nevertheless, the NPS conducted outreach to tribes and Native Hawaiian Organizations, initiated consultation through two letters to tribal leaders, and conducted face-to-face consultation on this rule upon request. Additional information regarding the identified effects on Indian Tribes and these outreach and consultation efforts is contained in a document entitled ''Consultation with Indian Tribes (E.O. 13175) regarding the proposed 36 CFR 79.12,'' which is available at the following URL: *https://www.nps.gov/orgs/1187/upload/Tribal_Consultation_36_CFR_Part_79_12.pdf.*

Effects on the Energy Supply (E.O. 13211)

This rulemaking is not a significant energy action under the definition in Executive Order 13211; the rule is not likely to have a significant adverse effect on the supply, distribution, or use of energy, and the rule has not otherwise been designated by the Administrator of OIRA as a significant energy action. A Statement of Energy Effects is not required.

Drafting Information

This rule was written with the cooperation and consultation of the following Federal agencies and bureaus: U.S. Bureau of Indian Affairs, U.S. Bureau of Land Management, U.S. Bureau of Reclamation, U.S. Fish and Wildlife Service, U.S. Air Force, U.S. Army Corps of Engineers, U.S. Navy, and U.S. Forest Service. Each agency and bureau provided a specialist in the curation of archeological collections to participate in an informal interagency working group to provide expert advice during the drafting of this rule.

List of Subjects

36 CFR Part 79

Archives and records, Historic preservation, Indians—lands, Museums, Public lands.

43 CFR Part 3

Agriculture Department, Army Department, Historic preservation, Smithsonian Institution.

In consideration of the foregoing, the National Park Service and Department of the Interior amend 36 CFR part 79, and 43 CFR part 2, as set forth below:

PART 79—CURATION OF FEDERALLY OWNED OR ADMINISTERED ARCHEOLOGICAL COLLECTIONS

■ 1. The authority citation for part 79 is revised to read as follows:

Authority: 16 U.S.C. 470aa–mm, 54 U.S.C. 300101 *et seq.*

■ 2. Revise the part heading to read as shown above.

§§ 79.1 through 79.4 [Designated as Subpart A]

■ 3. Designate §§ 79.1 through 79.4 as subpart A and add a heading for subpart A to read as follows:

Subpart A—Administrative Provisions

§ 79.1 [Amended]

■ 4. In § 79.1 amend paragraph (a) by:
■ a. Removing ''(16 U.S.C. 431–433)'' and adding, in its place, ''(54 U.S.C. 320301–320303)'';
■ b. Removing ''(16 U.S.C. 469–469c)'' and adding, in its place, ''(54 U.S.C. 312501–312508)''; and
■ c. Removing ''(16 U.S.C. 470h-2)'' and adding, in its place, ''(54 U.S.C. 306101–306114)''.

■ 5. In § 79.2:
■ a. Revise paragraph (a).
■ b. In paragraph (b)(2), remove ''(16 U.S.C. 431–433)'' and add, in its place, ''(54 U.S.C. 320301–320303)'' and remove ''(16 U.S.C. 469–469c)'' and add, its place, ''(54 U.S.C. 312501–312508)''.

The revision reads as follows:

§ 79.2 Authority

(a) The regulations in this part are promulgated under 54 U.S.C. 302107 which requires that the Secretary of the Interior issue regulations ensuring that significant prehistoric and historic artifacts and associated records are deposited in an institution with adequate long-term curatorial capabilities. This requirement applies to artifacts and associated records subject to the National Historic Preservation Act (54 U.S.C. 300101 *et seq.*), the Reservoir Salvage Act (54 U.S.C. 312501–312508), and the Archaeological Resources Protection Act (16 U.S.C. 470aa–mm).

* * * * *

■ 6. In § 79.3, revise paragraph (a) to read as follows:

§ 79.3 Applicability.

(a) Except as otherwise stated in this section, the regulations in this part apply to collections, as defined in § 79.4 of this part, that are excavated or removed under the authority of the Antiquities Act (54 U.S.C. 320301–320303), the Reservoir Salvage Act (54 U.S.C. 312501–312508), section 110 of the National Historic Preservation Act (54 U.S.C. 306101–306114) or the Archaeological Resources Protection Act (16 U.S.C. 470aa–mm). Such collections generally include those that are the result of a prehistoric or historic resource survey, excavation or other study conducted in connection with a Federal action, assistance, license, or permit. Such collections include those that are owned by the United States and for which a Federal agency has practical management authority, either directly or indirectly, as a result of that ownership; and those collections that are not owned by the United States but that are managed or controlled by a Federal agency pursuant to the laws cited in this paragraph (a).

* * * * *

■ 7. Revise § 79.4 to read as follows:

§ 79.4 Definitions.

As used for purposes of this part:

Associated records means original records (or copies thereof) that are prepared, assembled and document efforts to locate, evaluate, record, study, preserve or recover a prehistoric or historic resource. Some records such as field notes, artifact inventories and oral histories may be originals that are prepared as a result of the field work, analysis, and report preparation. Other records such as deeds, survey plats, historical maps and diaries may be copies of original public or archival documents that are assembled and studied as a result of historical research. Classes of associated records (and illustrative examples) that may be in a collection include, but are not limited to:

(1) Records relating to the identification, evaluation, documentation, study, preservation, or recovery of a resource (such as site forms, field notes, drawings, maps, photographs, slides, negatives, films, video and audio cassette tapes, oral histories, artifact inventories, laboratory reports, computer cards and tapes, computer disks and diskettes, printouts of computerized data, manuscripts, reports, and accession, catalog, and inventory records);

(2) Records relating to the identification of a resource using remote sensing methods and equipment (such as satellite and aerial photography and imagery, side scan sonar, magnetometers, subbottom profilers, radar, and fathometers);

(3) Public records essential to understanding the resource (such as deeds, survey plats, military and census records, birth, marriage and death certificates, immigration and naturalization papers, tax forms and reports);

(4) Archival records essential to understanding the resource (such as historical maps, drawings and photographs, manuscripts, architectural and landscape plans, correspondence, diaries, ledgers, catalogs, and receipts); and

(5) Administrative records relating to the survey, excavation, or other study of the resource (such as scopes of work, requests for proposals, research proposals, contracts, antiquities permits, reports, documents relating to compliance with section 106 of the National Historic Preservation Act (16 U.S.C. 470f), and National Register of Historic Places nomination and determination of eligibility forms).

Collection means material remains that are excavated or removed during a survey, excavation, or other study of a prehistoric or historic resource, and associated records that are prepared or

assembled in connection with the survey, excavation, or other study.

Curatorial services means managing and preserving a collection according to professional museum and archival practices, including, but not limited to:

(1) Inventorying, accessioning, labeling, and cataloging a collection;

(2) Identifying, evaluating, and documenting a collection;

(3) Storing and maintaining a collection using appropriate methods and containers, and under appropriate environmental conditions and physically secure controls;

(4) Periodically inspecting a collection and taking such actions as may be necessary to preserve it;

(5) Providing access and facilities to study a collection; and

(6) Handling, cleaning, stabilizing, and conserving a collection in such a manner to preserve it.

Departmental Consulting Archeologist means the individual serving as the agent of the Secretary of the Interior in overseeing and coordinating the Department's archeological activities.

Federal Agency Official means any officer, employee or agent officially representing the secretary of the department or the head of any other agency or instrumentality of the United States having primary management authority over a collection that is subject to this part.

Indian lands has the same meaning as in § -.3(e) of uniform regulations 43 CFR part 7, 36 CFR part 296, 18 CFR part 1312, and 32 CFR part 229.

Indian tribe has the same meaning as in § -.3(f) of uniform regulations 43 CFR part 7, 36 CFR part 296, 18 CFR part 1312, and 32 CFR part 229.

Material remains means artifacts, objects, specimens, and other physical evidence that are excavated or removed in connection with efforts to locate, evaluate, document, study, preserve or recover a prehistoric or historic resource. Classes of material remains (and illustrative examples) that may be in a collection include, but are not limited to:

(1) Components of structures and features (such as houses, mills, piers, fortifications, raceways, earthworks, and mounds);

(2) Intact or fragmentary artifacts of human manufacture (such as tools, weapons, pottery, basketry, and textiles);

(3) Intact or fragmentary natural objects used by humans (such as rock crystals, feathers, and pigments);

(4) By-products, waste products or debris resulting from the manufacture or use of man-made or natural materials (such as slag, dumps, cores and debitage);

(5) Organic material (such as vegetable and animal remains, and coprolites);

(6) Human remains (such as bone, teeth, mummified flesh, burials, and cremations);

(7) Components of petroglyphs, pictographs, intaglios, or other works of artistic or symbolic representation;

(8) Components of shipwrecks (such as pieces of the ship's hull, rigging, armaments, apparel, tackle, contents, and cargo);

(9) Environmental and chronometric specimens (such as pollen, seeds, wood, shell, bone, charcoal, tree core samples, soil, sediment cores, obsidian, volcanic ash, and baked clay); and

(10) Paleontological specimens that are found in direct physical relationship with a prehistoric or historic resource.

Personal property has the same meaning as in 41 CFR 100–43.001–14. Collections, equipment (*e.g.,* a specimen cabinet or exhibit case), materials and supplies are classes of personal property.

Provenience information means recorded data about the physical location of an object as it was found during a survey, excavation, or other study of a prehistoric or historic resource.

Public lands has the same meaning as in § -.3(d) of uniform regulations 43 CFR part 7, 36 CFR part 296, 18 CFR part 1312, and 32 CFR part 229.

Qualified museum professional means a person who possesses knowledge, experience and demonstrable competence in museum methods and techniques appropriate to the nature and content of the collection under the person's management and care, and commensurate with the person's duties and responsibilities. Standards that may be used, as appropriate, for classifying positions and for evaluating a person's qualifications include, but are not limited to, the following:

(1) The Office of Personnel Management's ''Position Classification Standards for Positions under the General Schedule Classification System'' (U.S. Government Printing Office, stock No. 906—028–00000–0 (1981)) are used by Federal agencies to determine appropriate occupational series and grade levels for positions in the Federal service. Occupational series most commonly associated with museum work are the museum curator series (GS/GM–1015) and the museum technician and specialist series (GS/GM–1016). Other scientific and professional series that may have collateral museum duties include, but are not limited to, the archivist series (GS/GM–1420), the archeologist series (GS/GM–193), the anthropologist series (GS/GM–190), and the historian series (GS/GM–170). In general, grades GS–9 and below are assistants and trainees while grades GS–11 and above are professionals at the full performance level. Grades GS–11 and above are determined according to the level of independent professional responsibility, degree of specialization and scholarship, and the nature, variety, complexity, type, and scope of the work.

(2) The Office of Personnel Management's ''Qualification Standards for Positions under the General Schedule (Handbook X–118)'' (U.S. Government Printing Office, stock No. 906–030–00000–4 (1986)) establish educational, experience and training requirements for employment with the Federal Government under the various occupational series. A graduate degree in museum science or applicable subject matter, or equivalent training and experience, and three years of professional experience are required for museum positions at grades GS–11 and above.

(3) The ''Secretary of the Interior's Standards and Guidelines for Archeology and Historic Preservation'' (48 FR 44716, Sept. 29, 1983) provide technical advice about archeological and historic preservation activities and methods for use by Federal, State, and local Governments and others. One section presents qualification standards for a number of historic preservation professions. While no standards are presented for collections managers, museum curators or technicians, standards are presented for other professions (*i.e.,* historians, archeologists, architectural historians, architects, and historic architects) that may have collateral museum duties.

(4) Copies of the Office of Personnel Management's standards, including subscriptions for subsequent updates, may be purchased from the Superintendent of Documents, U.S. Government Printing Office, Washington, DC 20402. Copies may be inspected at the Office of Personnel Management's Library, 1900 E Street NW, Washington, DC, at any regional or area office of the Office of Personnel Management, at any Federal Job Information Center, and at any personnel office of any Federal agency. Copies of the ''Secretary of the Interior's Standards and Guidelines for Archeology and Historic Preservation'' are available at no charge from the Interagency Resources Division, National Park Service, P.O. Box 37127, Washington, DC 20013–7127.

Religious remains means material remains that the Federal Agency Official

has determined are of traditional religious or sacred importance to an Indian tribe or other group because of customary use in religious rituals or spiritual activities. The Federal Agency Official makes this determination in consultation with appropriate Indian tribes or other groups.

Repository means a facility such as a museum, archeological center, laboratory, or storage facility managed by a university, college, museum, other educational or scientific institution, a Federal, State, or local Government agency or Indian tribe that can provide professional, systematic, and accountable curatorial services on a long-term basis.

Repository Official means any officer, employee or agent officially representing the repository that is providing curatorial services for a collection that is subject to this part.

Tribal Official means the chief executive officer or any officer, employee or agent officially representing the Indian tribe.

§§ 79.5 through 79.9 [Designated as Subpart B]

■ 8. Designate §§ 79.5 through 79.9 as subpart B and add a heading for subpart B to read as follows:

Subpart B—Archeological Collections Management

§ 79.10 [Designated as Subpart C]

■ 9. Designate § 79.10 as subpart C and add a heading for subpart C to read as follows:

Subpart C—Public Access to and Use of Collections

§ 79.11 [Designated as Subpart D]

■ 10. Designate § 79.11 as subpart D and add a heading for subpart D to read as follows:

Subpart D—Inspections and Inventories of Collections

■ 11. Add subpart E to read as follows:

Subpart E—Disposition of Particular Material Remains

Sec.

79.12 Determining which particular material remains are eligible for disposal.
79.13 Acceptable methods for disposition of particular material remains.
79.14 [Reserved].
79.15 Final determination of disposition of particular material remains.
79.16 Objecting to a determination of disposition of particular material remains.
79.17 Timing of disposition.
79.18 Administrative record of disposition.

§ 79.12 Determining which particular material remains are eligible for disposal.

(a) *Which material remains are eligible for disposal under this subpart?* In order to be eligible for disposal under this subpart, material remains from collections must be:

(1) Archaeological resources, as defined in the Archaeological Resources Protection Act (16 U.S.C. 470bb(1)), or other resources excavated and removed under the Reservoir Salvage Act (54 U.S.C. 312501–312508) or the Antiquities Act (54 U.S.C. 320301–320303); and

(2) Considered to be of insufficient archeological interest under the criteria in paragraph (e) of this section, based on the definition of ''of archaeological interest'' in 43 CFR 7.3(a)(1).

(b) *Which material remains are not eligible for disposal under this subpart?* The following material remains from collections are not eligible for disposal under this subpart:

(1) Native American ''cultural items'' as defined in the Native American Graves Protection and Repatriation Act of 1990 (25 U.S.C. 3001(3)), because disposition is governed by that Act and its implementing regulations (43 CFR part 10);

(2) Other human remains not subject to the Native American Graves Protection and Repatriation Act of 1990;

(3) Material remains excavated and removed from Indian lands on or before the enactment of the Archaeological Resources Protection Act (16 U.S.C. 470aa–mm) on October 31, 1979; and

(4) Material remains excavated and removed from Indian lands under the Antiquities Act (54 U.S.C. 320301–320303).

(c) *Who may propose the disposal of particular material remains?* The following individuals who meet the applicable Professional Qualification Standards set by the Secretary of the Interior may propose the disposal of particular material remains from a collection:

(1) Federal agency staff members with verifiable knowledge of the particular material remains, including archeologists, curators, and conservators; and

(2) Qualified museum professionals located in a repository that provides curatorial services for a collection held in that repository.

(d) *Who is responsible for the disposal of particular material remains?* The Federal Agency Official is responsible for ensuring that particular material remains are disposed of according to the requirements of this subpart.

(e) *When are particular material remains considered to be of insufficient archeological interest?* Particular material remains are considered to be of insufficient archeological interest when, on a case-by-case basis, at least one qualified archeological or museum professional who meets the Professional Qualification Standards set by the Secretary of the Interior and possesses verifiable knowledge of and experience in the type of material remains being evaluated makes a determination. The determination must follow the process established in § 79.15 and document that:

(1) Disposition of the material remains will not negatively impact the overall integrity of the original collection recovered during the survey, excavation, or other study of a prehistoric or historic resource; and

(2) At least one of the following three requirements—lack of provenience information; lack of physical integrity; or overly redundant and not useful for research—are met:

(i) *Lack of provenience information.* Lack of provenience information may be established after a concerted effort to recover the information in the related associated records is performed and documented and by one or more of the following circumstances:

(A) The labels on the material remains or the labels on the containers that hold the material remains do not provide adequate information to reliably establish meaningful archeological context for the material remains;

(B) The labels on the material remains or the labels on the containers that hold the material remains have been lost or destroyed over time and cannot be reconstructed through the associated records; or

(C) The associated records of the material remains never existed, have been lost, or have been destroyed.

(ii) *Lack of physical integrity.* Material remains lack physical integrity when, subsequent to recovery during the survey, excavation, or other study of a prehistoric or historic resource, the material remains were irreparably damaged through decay, decomposition, or inadvertent loss. Examples may include human-caused incidents, exposure to elements, or natural disaster.

(iii) *Overly redundant and not useful for research.* Material remains are overly redundant and not useful for research in light of the collection's archeological context, research questions, and research potential. These considerations may vary based on geography, time and culture period, scientific or cultural significance, prior analysis, and other factors. Because it is difficult to predict if future analytical methods will yield

useful information about the material remains proposed for disposal, a sample of the material remains deemed to be overly redundant and not useful for research must be retained for curation, as required by § 79.15(f).

§ 79.13 Acceptable methods for disposition of particular material remains.

(a) *Indian lands.* This paragraph applies to material remains that are determined to be of insufficient archeological interest under § 79.12(e) and that were excavated or removed from Indian lands after October 31, 1979. Under the Archaeological Resources Protection Act (16 U.S.C. 470aa–mm), these material remains are the property of the Indian individual or Indian tribe having rights of ownership over the resources. Under the authority of 16 U.S.C. 470dd, disposition of these material remains is subject to the consent of the Indian individual or Indian tribe. The Federal Agency Official must use the following methods of disposal for these material remains in the following order:

(1) Return them to the Indian individual or Indian tribe having rights of ownership under the Archaeological Resources Protection Act's custody regulations, 43 CFR 7.13(b), 36 CFR 296.13(b), 32 CFR 229.13(b), and 18 CFR 1312.13(b).

(2) If the Indian individual or Indian tribe having rights of ownership does not wish to accept and take physical custody of the material remains, the Federal Agency Official may otherwise dispose of the material remains using the disposition methods in paragraph (b) of this section after receiving written consent and relinquishment of ownership from the Indian individual or Indian tribe having rights of ownership.

(b) *Public lands.* This paragraph applies to material remains that are determined to be of insufficient archeological interest under § 79.12(e) and that were excavated or removed from public lands that are not Indian lands. As a condition of disposal, the Federal Agency Official will reasonably ensure that material remains from such lands may not be traded, sold, bought, or bartered after disposal. The Federal Agency Official must consider the following methods for disposal of the material remains:

(1) Transfer to another Federal agency.

(2) Convey to a suitable public or tribal scientific or professional repository as defined in § 79.4(k) of this part.

(3) Convey to a federally recognized Indian tribe if the material remains were excavated or removed from lands of religious or cultural importance to that tribe and were identified and documented by a Federal land manager under 43 CFR 7.7(b)(1), 36 CFR 296.7(b)(1), 32 CFR 229.7(b)(1), or 18 CFR 1312.7(b)(1).

(4) Convey to a federally recognized Indian tribe from whose aboriginal lands the material remains were removed. Aboriginal occupation may be documented by evidence including, but not limited to, a final judgment of the Indian Claims Commission or the United States Court of Claims, or a treaty, Act of Congress, or Executive Order.

(5) Convey to a federally recognized Indian tribe for the purpose of traditional cultural, educational, or religious practices.

(6) Transfer within the Federal agency for the purpose of education or interpretation, or convey to a suitable institution to be used for public benefit and education including, but not limited to, local historical societies, museums, university or college departments, and schools.

(7) If the Federal Agency Official considers each of these prior methods carefully and is still unable to find an acceptable method of disposition, then the material remains may be destroyed. The Federal Agency Official or their designee must witness and document the destruction, including through photography or video as practicable.

§ 79.14 [Reserved]

§ 79.15 Final determination of disposition of particular material remains.

The Federal Agency Official is responsible for ensuring that the agency disposes of material remains according to the requirements of this subpart. A determination made under this subpart in no way affects a Federal land manager's obligations under other applicable laws or regulations. The Federal Agency Official must take all the following actions before making a final determination that it is appropriate to dispose of material remains.

(a) The Federal Agency Official must determine that the material remains are eligible for disposal under the criteria in § 79.12(a).

(b) The Federal Agency Official must verify in writing that none of the material remains proposed for disposal meet the criteria in § 79.12(b).

(c) The Federal Agency Official must verify that the material remains proposed for disposal are appropriately documented through a professional procedure approved by the Federal agency that is consistent with curatorial services, including accessioning and cataloging, as defined in § 79.4(b).

(d) The Federal Agency Official must consult with qualified museum professionals located in the repository that provides curatorial services for the material remains proposed for disposal if those museum professionals did not propose the disposal under § 79.12(c)(2). This consultation with the qualified museum professionals must address the appropriateness of the proposed disposal.

(e) The Federal Agency Official must establish a collections advisory committee of at least five members to review proposed dispositions of material remains. The committee must make a consensus recommendation to the Federal Agency Official about each proposed disposition based on the adequacy of the documentation addressing the requirements in paragraphs (a) and (b) of this section and the appropriateness of the proposed disposition based on the criteria in § 79.12(e).

(1) The collections advisory committee must consist of qualified employees from Federal agencies who meet appropriate Professional Qualification Standards set by the Secretary of the Interior, and must include the curator and the principal archeologist of the Federal agency that owns or administers the material remains if either or both of these two positions exist. The Departmental Consulting Archeologist may not participate on the collections advisory committee. If the Departmental Consulting Archeologist is the principal archeologist, then the Federal Agency Official must designate another qualified archeologist at the agency instead.

(2) Collections advisory committee members must include Federal employees with subject matter or technical expertise in the object types, cultural period, and culture area of the proposed disposition. These employees may include archeologists, anthropologists, curators, and conservators with expertise in historic, prehistoric, or underwater material remains.

(3) If the material remains being proposed for disposal are Native American, then collections advisory committee members must also include at least one or more individuals who are Tribal Officials acting in their official capacities representing their respective federally recognized Indian tribes that are regularly consulted by the Federal agency regarding the collection containing the material remains being proposed for disposal.

(4) The collections advisory committee must have written

procedures and governing rules, including terms of member appointments and the duration of the committee, approved by the Federal Agency Official, to ensure all recommendations about the appropriateness of disposal are fair, open, timely, and in the best interests of the public.

(5) The collections advisory committee must submit a written report to the Federal Agency Official for each proposed disposition that, at a minimum, documents the information required for the **Federal Register** notice identified in paragraphs (i)(1)(i) through (iii) of this section; membership of the committee and each member's role and expertise pertinent to the proposed disposition; a summary of any comments received on the proposed disposition under paragraph (h) of this section; the recommendations for disposition, including any conditions of transfer or conveyance; and the reasons why other methods of disposal would be of lesser public benefit.

(6) Federal employees or qualified members of federally recognized Indian tribes may be temporarily added to the committee if its existing members determine that specific expertise, including archeological knowledge of the cultural period and cultural area, is needed on a case-by-case basis.

(7) Collections advisory committee members, whether permanent or temporary, and their family members may not benefit financially or in any other way from a disposition of material remains, except to the extent that members of a federally recognized Indian Tribe, when that Indian Tribe is being considered as a potential recipient of material remains, may participate in the collections advisory committee as described in § 79.15(e)(3).

(f) The Federal Agency Official must retain in the curated collection a sample of those material remains determined to be overly redundant and not useful for research that is representative of the population as a whole from which the sample was taken.

(1) The size of the representative sample must be large enough to permit future analysis for research purposes.

(2) The method for establishing a representative sample, including sample size and typology, must be determined by a qualified museum or archeological professional with expertise in the type of prehistoric or historic material remains being sampled.

(3) The sampling method must be documented and consistent with professional prehistoric or historic archeological practice.

(g) The Federal Agency Official must retain all associated records in the archeological collection as defined in § 79.4(a)(2). A copy of the original associated records must be given to the recipient of any transferred or conveyed items subject to the restrictions stipulated in the Archaeological Resources Protection Act (16 U.S.C. 470hh(a)). For material remains excavated and removed from Indian land, a copy of the original associated records must be given to the Tribal Historic Preservation Officer (or other designated tribal representative) from the tribal land where the material remains were recovered.

(h) The Federal Agency Official must notify the entities listed in this paragraph of the proposed disposition and solicit comments on the proposal. Notifications must be made in writing, and must include a deadline for submitting comments that is at least 60 days after notice is issued, in accordance with procedures established by the Federal agency. All written comments must be reviewed by the Federal Agency Official and the collections advisory committee. The Federal Agency Official will respond to all relevant, substantive comments received. Notice must be given to the following:

(1) The State Historic Preservation Officer and, where established, the State Archeologist, from the state(s) where the material remains to be disposed of were recovered.

(2) The Tribal Historic Preservation Officer (or other designated tribal representative) from the Indian land(s) where the material remains to be disposed of were recovered.

(3) Federal, state, tribal, or local agencies that were involved in the recovery of the material remains to be disposed of.

(4) Private landowners from whose lands the material remains to be disposed of were removed, but only in such cases where the Federal agency obtained practical management authority over the material remains as the result of activities conducted in connection with a Federal action, assistance, license, or permit, on those private lands.

(5) Universities, museums, scientific institutions, and educational institutions with which the agency has an existing relationship pursuant to a written instrument (*e.g.,* permit, agreement) for research, excavation, curation, education, or other partnership in the state and region from which the material remains to be disposed of were recovered.

(6) Indian tribes that consider the land to have religious or cultural importance, if the material remains are from a site on public lands that has religious or cultural importance to Indian tribes under 43 CFR 7.7(b)(1).

(7) Indian tribes from whose aboriginal lands the material remains were removed, if aboriginal occupation has been documented by a final judgment of the Indian Claims Commission or the United States Court of Claims, treaty, Act of Congress, or Executive Order.

(i) The Federal Agency Official must, after the comment period described in paragraph (h) of this section has expired and the Federal Agency Official has responded to all relevant, substantive comments received, publish a notice of determination of disposition in the **Federal Register**.

(1) The notice published in the **Federal Register** must include the following:

(i) A general description of the material remains to be disposed.

(ii) The criteria used to determine that the material remains are of insufficient archeological interest under § 79.12(e).

(iii) The method of disposal.

(iv) The name of the Federal Agency Official or their designee as a point of contact.

(v) An explanation of a person's right to object to the determination of disposition under § 79.16 and the name, email, and physical address of the Departmental Consulting Archeologist.

(2) The Federal Agency Official must also prepare a determination of disposition that includes the following:

(i) A detailed list of the material remains to be disposed, including a description of each object, or lot of objects if there are multiples of a particular type, and photograph(s) of the objects when appropriate.

(ii) The report of the collections advisory committee as stipulated in paragraph (e)(5) of this section.

(iii) Documentation that all of the procedures in § 79.15 have been met.

(iv) The name of the recipient entity or method of disposal, as appropriate.

(v) Justification of the method to be used to dispose of the material remains under § 79.13.

(vi) The name of the Federal Agency Official or their designee as a point of contact.

(vii) Other conditions of transfer or conveyance, as appropriate.

(viii) A statement that the determination is a final agency action under the Administrative Procedure Act (5 U.S.C. 704) unless an objection is filed in accordance with § 79.16.

§ 79.16 Objecting to a determination of disposition of particular material remains.

Anyone may object to and request in writing that the Departmental Consulting Archeologist review a Federal Agency Official's determination to dispose of material remains within 60 days of publication of the notice of determination of disposition in the **Federal Register**. The objection must document why the objector disagrees with the Federal Agency Official's decision regarding the disposal. The procedure for objecting to a determination of disposition is as follows:

(a) The objection must be sent to the Departmental Consulting Archeologist. The Departmental Consulting Archeologist must forward a copy of the objection within 5 days of receipt to the Federal Agency Official who made the determination under objection. The Federal Agency Official must halt the planned disposition until the Departmental Consulting Archeologist completes the requested review.

(b) The Departmental Consulting Archeologist must review the objection, and the Federal Agency Official's determination of disposition in § 79.15(i)(2).

(c) The Departmental Consulting Archeologist must consult with the objecting party or parties and the Federal Agency Official with the aim of resolving the objection.

(d) Within 60 days of receipt of the objection, whether or not a formal resolution has been agreed upon, the Departmental Consulting Archeologist must transmit to the Federal Agency Official a non-binding recommendation, including a thorough explanation, for further consideration.

(e) The Federal Agency Official must consider the recommendation of the Departmental Consulting Archeologist prior to making a decision on the objection. Within 30 days of receipt of the recommendation, the Federal Agency Official must respond to the Departmental Consulting Archeologist and the objector with a decision on the objection and a justification for that decision. The decision document must include any information about administrative appeal rights required by internal agency appeal procedures or a statement that the decision document is a final agency action under the Administrative Procedure Act, as appropriate.

(f) The Federal Agency Official must publish notice of the decision on the objection and any amendments made to the determination of disposition in the **Federal Register**. This may only be done after the objector exhausts any internal appeal procedures identified in the decision document sent to the objector under § 79.16(e). Publication of the notice of the decision on the objection constitutes a final agency action under the Administrative Procedure Act (5 U.S.C. 704).

§ 79.17 Timing of disposition.

Disposition will occur no sooner than 60 days after the notice of determination of disposition is published in the **Federal Register** under § 79.15(i). If the Federal agency receives an objection under § 79.16, then disposition will occur no sooner than 30 days after the notice of decision on the objection and any amendments are published in the **Federal Register** under § 79.16(f).

§ 79.18 Administrative record of disposition.

(a) After the Federal Agency Official has made a determination of disposition, he or she must document the determination and retain the administrative record as part of the associated records as defined in § 79.4(a)(2), which must include:

(1) The professional evaluation of the material remains conducted under §§ 79.12(e) and 79.15(b).

(2) The report of the collections advisory committee provided under § 79.15(e)(5).

(3) Notifications of the proposed disposition under § 79.15(h); consent of Indian individuals or tribes, if applicable, under § 79.13(a)(2); and comments received from the parties notified under § 79.15(h).

(4) Objections received by the Departmental Consulting Archeologist, the non-binding recommendation of the Departmental Consulting Archeologist, and the decision on the objection and any amendments made to the determination of disposition, if applicable, under § 79.16.

(5) The disposition action with specific information, including a description and evaluation of objects; the method of disposition and the reason for the method chosen; names and titles of persons initiating and approving the disposition; date of disposition; relevant accession and catalog numbers; evidence of the receipt for the return, transfer, or conveyance of the material remains by the recipient tribe, agency, repository, or institution, including the title to the received material remains, as appropriate; photographic documentation, as appropriate; and the name and location of the recipient institution or entity, as appropriate.

(6) A detailed inventory of the representative sample of material remains retained, when the larger proportion is disposed of because it is overly redundant and not useful for research.

(7) Other activities and decisions pertaining to the disposition of the material remains, such as conditions of use after the disposition is completed, as appropriate.

(b) The administrative record must be made available to the public upon request, unless the information or a portion of it must be withheld under the terms of the Freedom of Information Act (5 U.S.C. 552) or the Archaeological Resources Protection Act (16 U.S.C. 470hh). The latter restricts the government's ability to make sensitive information, such as archeological site location data, available to the public.

(c) After disposition, the accession and catalog records must be reviewed and amended through a procedure established by the Federal agency. The amendments must identify the material remains that were deaccessioned and disposed of, the date of disposition, and the manner in which they were disposed. The documentation prepared under § 79.15, § 79.16, and paragraph (a) of this section must be retained in accordance with Federal agency policy.

TITLE 43: PUBLIC LANDS: INTERIOR

SUBTITLE A—OFFICE OF THE SECRETARY OF THE INTERIOR

PART 3—PRESERVATION OF AMERICAN ANTIQUITIES

■ 12. The authority citation for part 3 is revised to read as follows:

Authority: 54 U.S.C. 320302–320303.

■ 13. Amend § 3.17 by adding a note at the end of the section to read as follows:

§ 3.17 Preservation of Collection

* * * * *

Note to § 3.17: Regulations concerning curation of federally owned or administered archeological collections are found in 36 CFR part 79. Objects excavated under the Antiquities Act may be eligible for disposal under subpart E of 36 CFR part 79.

Shannon A. Estenoz,

Assistant Secretary for Fish and Wildlife and Parks.

BILLING CODE 4312–52–P

INTRODUCTION

The following appendix describes the Inadvertent Discovery Plan for Cultural Resources or Human Remains for the "*Removal of Four Beautification (Low-Head) Dams in the Grand River, Grand Rapids, Kent County, Michigan, a component of the Lower Grand River Watershed Habitat Restoration and Farmland Conservation Project*." The procedure outlined below conforms to MI-NRCS general Procedure for Construction Discovery but in this instance covers only items of cultural resource not attributable to the architecture of the low-head dams. Any discovered human remains are subject to this Inadvertent Discovery Plan.

RECOGNIZING CULTURAL RESOURCES

A cultural resource discovery is an item of presumed human manufacture and likely to be greater than 50 years of age. Examples include but are not limited to:

- Stone tools or debitage (i.e., arrow head or chipped stone waste flakes),
- Clusters of tin cans, ceramics, bottles, logging implements, agricultural equipment etc., that appears older than 50 years

UPON DISCOVERING CULTURAL RESOURCES

In the event that any NRCS staff, consultant, local agency representative, contractor, landowner, etc. discover a cultural resource during removal of the low-head dams, they must immediately notify the construction manager, who will, in response: 1. cease operations in that location and 2. notify the NRCS Cultural Resources Specialist.

If the action affecting the resource is not halted, continuing to affect the resource may result in withdrawal of NRCS assistance. Pursuant to Section 110(k) of the National Historic Preservation Act and the NRCS National Cultural Resources Procedures Handbook, Subpart C, Section 601.27, the NRCS must ensure that Federal assistance is NOT used to cause or further an adverse impact to a cultural resource.

UPON DISCOVERING HUMAN REMAINS

The following steps will be implemented if human remains and/or materials subject to NAGPRA are inadvertently discovered during this Project. This largely follows the steps set forward in Michigan Attorney General Opinion No. 6585 of 1989, *Cemeteries and Dead Bodies*, those recommended by the State Historic Preservation Office, and those recommended by the Match-E-Be-Nash-She-Wish Band of Pottawatomi Indians (Gun Lake Tribe) who reviewed and commented on this permit application.

If the action affecting the remains is not halted, continuing to affect the remains may result in withdrawal of NRCS assistance.

Human Remains and Associated Materials

1. Upon the discovery of human remains and any associated materials, excavation in the immediate vicinity is halted. Cover and secure the area and do not handle finds. All Project personnel shall treat any discovery as confidential.

2. The local police authority is immediately notified so that they may evaluate the site.

3. Immediately notify the NRCS, who will then notify the Match-E-Be-Nash-She-Wish Band of Pottawatomi Indians THPO, SHPO archaeologists and any additional tribes who requested consultation with NRCS.

4. If the police determine that human remains represent evidence of a crime or missing person, they will complete their investigation.

5. If the police determine that human remains do not represent evidence of a crime or missing person, the burial will be adequately documented and preserved in place or relocated as determined through appropriate consultation. It is preferred that burial sites be preserved and maintained in place. If this is not possible, the remains and any associated materials would need to be moved for their protection.

The following sequence of steps will be employed if it is not possible to preserve and maintain an inadvertently discovered burial in place:

1. Excavations shall be respectful and conducted out of public view, to the extent possible.

2. A qualified archaeologist experienced in human remains recovery shall recover the remains and any related materials that may be present. Archaeological expertise is important in documenting the discovery context and evaluating whether the remains are isolated or if additional remains may be immediately present. Archaeological recovery may be done under the auspices of law enforcement. If law enforcement chooses not to be involved, a permit for disinterment must be obtained from the local Department of Public Health, or through a court order.

3. As soon as possible, the remains shall be examined by a physical anthropologist using standard non-invasive methods and procedures to create a basic biological profile and estimate ethnicity.

4. Draft and final archaeological reports, with related physical anthropological reports and law enforcement case documentation appended, will be submitted to the NRCS, Match-E-Be-Nash-She-Wish Band of Pottawatomi Indians THPO, and SHPO archaeologists.

Discoveries of Native American Ancestors and/or Other Materials Subject to NAGPRA

1. If it can be determined immediately that a discovery is, or has the potential to be, a Native American Ancestor and/or other materials subject to NAGPRA (i.e., associated or unassociated funerary objects, sacred objects, and objects of cultural patrimony), the Match-E-Be-Nash-She-Wish Band of Pottawatomi Indians (and any other consulting Tribes) will be notified within 72 hours of discovery and potential identification. Tribal notification and consultation will be coordinated by the NRCS and SHPO archaeologists. After notification and initial consultation, consulting Tribes may request that all federally recognized Tribes likely to be culturally affiliated with the discovery be notified in writing by mail or email and further consultation initiated regarding the cultural affiliation, care, handling, excavation (if necessary), and/or disposition per NAGPRA.

2. Known or suspected Native American Ancestors or other materials subject to NAGPRA will not be moved, touched, or further disturbed after discovery until completion of Tribal consultation or emergent circumstances arise.

3. Accommodations will be made for traditional or ceremonial practices in association with discoveries.

4. Photographs shall not be taken, except when necessary for identification and documentation. Tribes may request that any photographs of Native American Ancestors or other materials subject to NAGPRA be destroyed or repatriated at the end of the Project.

5. Pending consultations, documentation of the discovery will include a written description, mapping and sketching, and precise GPS coordinates. This documentation will be curated with other Project records and not be published or made publicly available in any way.

6. To ensure the protection, preservation, and proper respectful treatment of any discovered materials, pursuant to applicable law, the nature and location of any discovery shall remain confidential as best as reasonably possible given the circumstances and location. Only those persons and entities identified in this plan shall be notified of the discovery or given information about the discovery. The Permittee, NRCS, SHPO, and related contractors will ensure all staff and consulting personnel are appropriately trained for their respective roles in implementing this plan.

7. Consulting Tribes will be afforded opportunities to employ proper traditional cultural practices and treatments during periods of non-Tribal holding of discoveries.

8. The permanent care of Native American Ancestors and materials subject to NAGPRA will be determined by the appropriate Tribe or Tribes in consultation with the SHPO.

9. Draft and final archaeological reports, with related physical anthropological reports and law enforcement case documentation appended, will be submitted to the appropriate Tribes for review and comment.

Additional Notes
The Match-E-Be-Nash-She-Wish Band of Pottawatomi Indians (Gun Lake Tribe) has notified the NRCS and SHPO that they wish to consult if Native American Ancestors or cultural materials are found. This Tribe will be consulted in addition to those who requested consultation with the NRCS.

Appendix G – *Glossary of Terms*

ACHP – Advisory Council on Historic Preservation is an independent federal agency created solely to address historic preservation issues. It promotes the preservation, enhancement, and sustainable use of our nation's historic resources. The ACHP advises and guides federal agencies and participants through the Section 106 review process.

City – The City of Grand Rapids, Michigan is the sponsoring local organization, EGLE permit applicant and responsible for establishing contracts for demolition work. The City is an invited signatory.

GRPM – Grand Rapids Public Museum, a concurring party.

GRWW – Grand Rapids Whitewater, Inc. is leading the design and engineering of the Project and will closely coordinate with the City and other partners to accomplish the intent of the design. GRWW is an invited signatory.

GVMC – Grand Valley Metropolitan Council is the applicant for federal assistance through the RCPP and is responsible for ensuring habitat restoration work and requirements of the RCPP agreement are met. GVMC is an invited signatory.

MOA – Memorandum of Agreement. This MOA serves to document steps that will be taken to mitigate the adverse effects caused by the removal of the four low-head dams in the Grand River in downtown Grand Rapids as part of the Lower Grand River Watershed Habitat Restoration and Farmland Conservation Project.

MSF – Michigan Strategic Fund, a signatory.

NHPA – National Historic Preservation Act

NRCS – Natural Resources Conservation Service, a federal agency of the U.S. Department of Agriculture. NRCS is the lead federal agency for this MOA and is a signatory.

SHPO – State Historic Preservation Office, a signatory.

Signatory Status – Parties who may sign a MOA fall into 1 of 3 categories:
(from: https://www.achp.gov/executing_agreement_documents)

1. **Signatory** – In accordance with 36 CFR Part 800.6(c)(1), a signatory has the sole authority to execute, amend, or terminate the agreement. The federal agency and the SHPO/THPO are signatories. The ACHP is a signatory when it chooses to participate. A THPO or tribal representative is a required signatory when the undertaking occurs on or affects historic properties on tribal lands.

2. **Invited Signatory** - In accordance with 36 CFR Part 800.6(c)(2), an invited signatory, upon signing, has the authority to amend and terminate the agreement. The federal agency official may invite additional parties to sign the agreement such

as an Indian tribe who attaches religious and cultural significance to historic properties affected by the undertaking (off tribal lands), or any party that assumes a responsibility under the agreement.

3. **Concurring Party** – In accordance with 36 CFR Part 800.6(c)(3), a concurring party is a consulting party invited to concur in the agreement document but who does not have the authority to amend or terminate the agreement. A concurring signature is essentially an endorsement of the agreement.

Consulting Party – Consulting Party status entitles the person or group to share their views, receive and review pertinent information, offer ideas, and consider possible solutions together with the federal agency and other consulting parties. Each party can decide how active a role they wish to play in consultation.

ABSTRACT

The Michigan State Historic Preservation Office (MI SHPO) has requested a National Register of Historic Places (NRHP) evaluation of the eligibility of four low-head dams in the Grand River in Grand Rapids, Michigan that would be affected by the Grand Rapids Whitewater Project (Project), which proposes the removal of these dams. With the support of the City of Grand Rapids and Grand Rapids Whitewater (GRWW), Environmental Resources Management (ERM) prepared this report evaluating whether the beautification dams constructed along the Grand River in the early twentieth century are eligible for the NRHP, and if so, whether the Project may result in adverse effects to these cultural resources. The U.S. Department of Agriculture's Natural Resources Conservation Service (NRCS) is the lead federal agency with funding authority over the undertaking.

The Project spans approximately 0.7 miles along the downtown portion of the Grand River, and includes the removal of four low-head, historic-aged dams associated with the early industrial and commercial growth of Grand Rapids, as well as other changes in the river. Another dam in the Grand River upstream of the Project, the Sixth Street Dam and Fish Passage, has already been recommended eligible for the NRHP, and has been addressed as a separate undertaking. This report evaluates the four dams located from just north of Bridge Street to just north of Pearl Street. In order to evaluate the significance of the dams, ERM collected information on the dams and their context within the history of Grand Rapids from experts knowledgeable in local history, city planning, and historical public works. Documents, maps, and photographs were collected from the Grand Rapids City Archive and Record Center, the Grand Rapids Public Museum, the Grand Rapids Public Library, and the Grand Rapids Historical Commission.

Based on the information gathered, ERM recommends that the four low-head dams, referred to as the Beautification Dams in Grand River, are potentially eligible for the NRHP. The dams meet the requirements for listing under Criterion A for their role in the emergence of city planning and the development of the riverfront as a focal point of downtown development in Grand Rapids, and under Criterion B for their association with city planner Harland Bartholomew, whose ideas on city beautification influenced the development of Grand Rapids during the twentieth century. ERM also recommends that the Project would have an adverse effect on the properties. The Project plan as currently proposed requires removal of all the dams and does not allow for avoidance or minimization of adverse effects. ERM recommends that, should MI SHPO concur with this assessment, a plan be developed to mitigate the adverse effects of the Project on the four low-head dams.

1. INTRODUCTION

1.1 Overview

Michigan State Historic Preservation Office (MI SHPO), in the course of consultation regarding the Project, has requested an evaluation of National Register of Historic Places (NRHP) eligibility of four low-head dams in the Grand River in Grand Rapids that would be affected by the Project, which proposes the removal of these dams in an effort to restore the river to a more natural state. With the support City of Grand Rapids and Grand Rapids Whitewater (GRWW), Environmental Resources Management (ERM) prepared this report evaluating whether the beautification dams constructed along the Grand River in the early twentieth century are potentially eligible for the NRHP, and if so, whether the Project may result in adverse effects to these cultural resources.

The Project requires funding authorization from the NRCS, and must comply with the provisions of the National Environmental Policy Act (NEPA) of 1970 and the National Historic Preservation Act (NHPA) of 1966. The need for federal authorization requires Project review under Section 106 of the NHPA, as amended. Section 106 of the NHPA (54 United States Code § 306108) requires federal agencies, including NRCS, to take into account the effects of their undertakings on historic properties and to afford the Advisory Council on Historic Preservation (ACHP) an opportunity to comment. Historic properties are defined as cultural resources that are listed or eligible for listing in the NRHP (36 Code of Federal Regulations [CFR] 60). GRWW, as a non-federal party, is assisting the Natural Resources Conservation Service (NRCS) in meeting its obligations under Section 106 by preparing the necessary information, analyses, and recommendations as authorized by 36 CFR § 800.2(a)(3).

On December 20, 2018, ERM, on behalf of NRCS, submitted a request for initial consultation regarding the Lower Grand River Watershed Habitat Restoration Project. On June 18, 2020, NRCS submitted an update to that submittal. MI SHPO responded on June 29, 2020 with a request for more information regarding the four low-head dams to be removed as part of the river restoration. Additional information was provided on November 2, 2020, to which MI SHPO responded with a request for further information regarding the known history and current condition of the four low-head dams (December 17, 2020, ER20-876). MI SHPO requested that additional information be provided about the dams to be removed by the Project, along with historical context that would help frame their potential eligibility for the NRHP. The current report was prepared to satisfy that request.

The Project includes the following:

- The Construction Area—the area within the wetted channel of the Grand River from approximately 130 feet upstream of the Bridge Street Bridge to the upstream edge of the Fulton Street Bridge
- The Project Area—the areas where Project activities would occur:
  - Portions of the land on both sides of the Grand River from the 6th Street Dam to Fulton Street (where construction access or staging areas would occur)
  - The wetted channel of the river from 130 feet upstream of the Bridge Street Bridge to the upstream face of the Fulton Street Bridge (the Construction Area)
  - Three recipient sites in the river for the placement of relocated unionid mussels. The three recipient sites are mussel beds near Ada, Michigan; at Riverside Park just upstream of Grand Rapids; and between Plaster Creek and the M-11 (28th Street) Bridge.

The Project's Area of Potential Effect (APE) is defined for direct effects as the Construction Area and Project Area, and for indirect effects as areas immediately adjacent to the Construction Area. Direct effects on the four low-head dams scheduled for removal are the subject of this report. Proposed earth

disturbance is not planned beyond the confines of the active river channel except for construction access points and temporary staging areas on the banks.

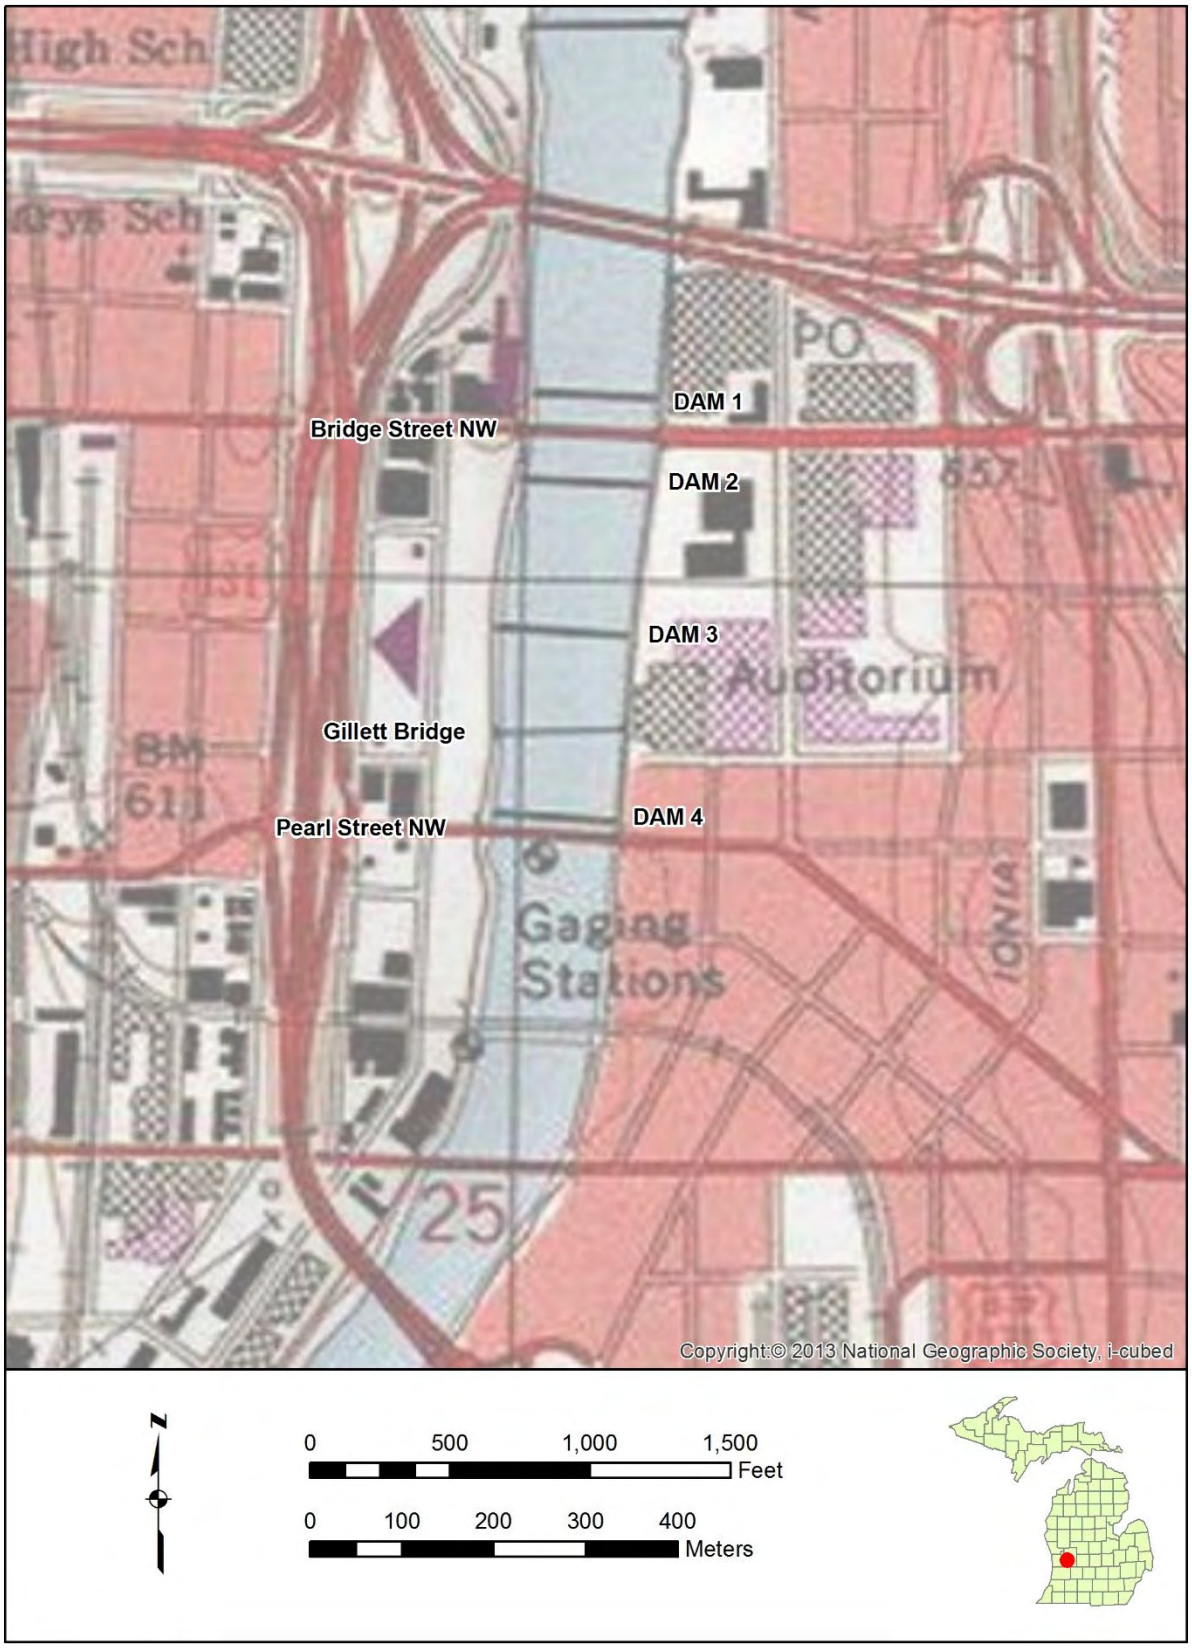

Figure 1.1-1: Topographic Map Showing Location of Dams

Figure 1.1-2: Current Aerial Imagery of Beautification Dams

The Project spans approximately 0.7 miles along the downtown portion of the Grand River, and includes the removal of four low-head, historic-aged dams associated with the twentieth century commercial growth of Grand Rapids, as well as other changes in and near the river (Figures 1.1-1 and 1.1-2). Another dam in the river at Grand Rapids, the Sixth Street Dam and Fish Passage, was constructed earlier than the other four, and was originally intended for water power. It was repaired and improved in 1926 as part of the planned improvements to the river recommended by city planner Harland Bartholomew. This dam has already been determined eligible for the NRHP (Robinson et al. 2020; B. Grennell to C. Sedlacek, letter dated 6 October, 2020). The current report evaluates the four dams located from just north of Bridge Street to just north of Pearl Street. In order to evaluate the significance of the dams, ERM collected information on the dams and their context from online sources and experts knowledgeable in local history, city planning, and historical public works. Documents, maps, and photographs were collected from the Grand Rapids City Archive and Record Center (GRCARC), the Grand Rapids Public Museum (GRPM), the Grand Rapids Public Library (GRPL), and the Grand Rapids Historical Commission (GRHC).

The four dams were constructed in 1927 as part of a plan to beautify the river through downtown. The creation of canals on both sides of the river for power and industrial use had led to low water levels in the river during dry periods, creating fetid pools and the growth of brush in the channel. The construction of low-head dams to create run-of-the-river pools had been recommended by Harlan Bartholomew as part of the 1925 City Plan (Bartholomew 1925). The proposed undertaking would entail removal of all four dams to reinstitute rapids in the riverbed, improving aquatic habitat diversity, improving public health and safety, expanding use of the river, and improving recreational use of the river. This report will evaluate the potential NRHP eligibility of the four Beautification Dams proposed for removal as part of the Project.

1.2 Management Recommendations

Based on the information gathered, ERM recommends that the four low-head dams, referred to as the Beautification Dams in Grand River, are eligible for the NRHP. The dams meet the requirements for listing under Criterion A for their role in the emergence of city planning and the development of the riverfront as a focal point of downtown development in Grand Rapids, and under Criterion B for their association with city planner Harland Bartholomew, whose ideas on city beautification influenced the development of Grand Rapids during the twentieth century. ERM also recommends that the Project would have an adverse effect on the properties. The Project as currently proposed requires removal of all the dams and does not allow for avoidance or minimization of adverse effects. ERM recommends that, should MI SHPO concur with this assessment, a plan be developed to mitigate the adverse effects of the Project

2. HISTORIC CONTEXT

When settlers began to congregate around the Baptist Mission on the west bank of the Grand River and the trading post established by Louis Campau on the east side of the river at what is now Grand Rapids in the 1820s, the river was described as a mile-long cascade of rapids that was 300 yards wide and dropped a total of 10 to 15 feet. A map made in 1830 (Grand Rapids Public Library 1830) shows the rapids that spanned the length of the city's street grid (Figure 2.0-1). The potential water power that the river could provide was immediately recognized, and by at least 1833, the river was being used for power. In 1835, the first dam was constructed on the river. The stone wing dam was located near Eleventh Street to the north of the Project area, and diverted water into the East Side Power Canal to provide waterpower to a sawmill and gristmill. The canal was extended for a mile along the river and was completed in 1842, providing power to a number of industries until it was abandoned in 1925. In 1849, a log and stone dam was constructed across the width of the river in an attempt to expand the canal for navigation. The canal project was a failure, but the horseshoe-shaped dam near Sixth Street remained until after 1878 (Figure 2.0-2) (Biolchini 2019; Robinson, et al. 2020).

Figure 2.0-1: Map of Grand Rapids in 1830 Showing the Rapids through the City (North is to the right) (GRPL)

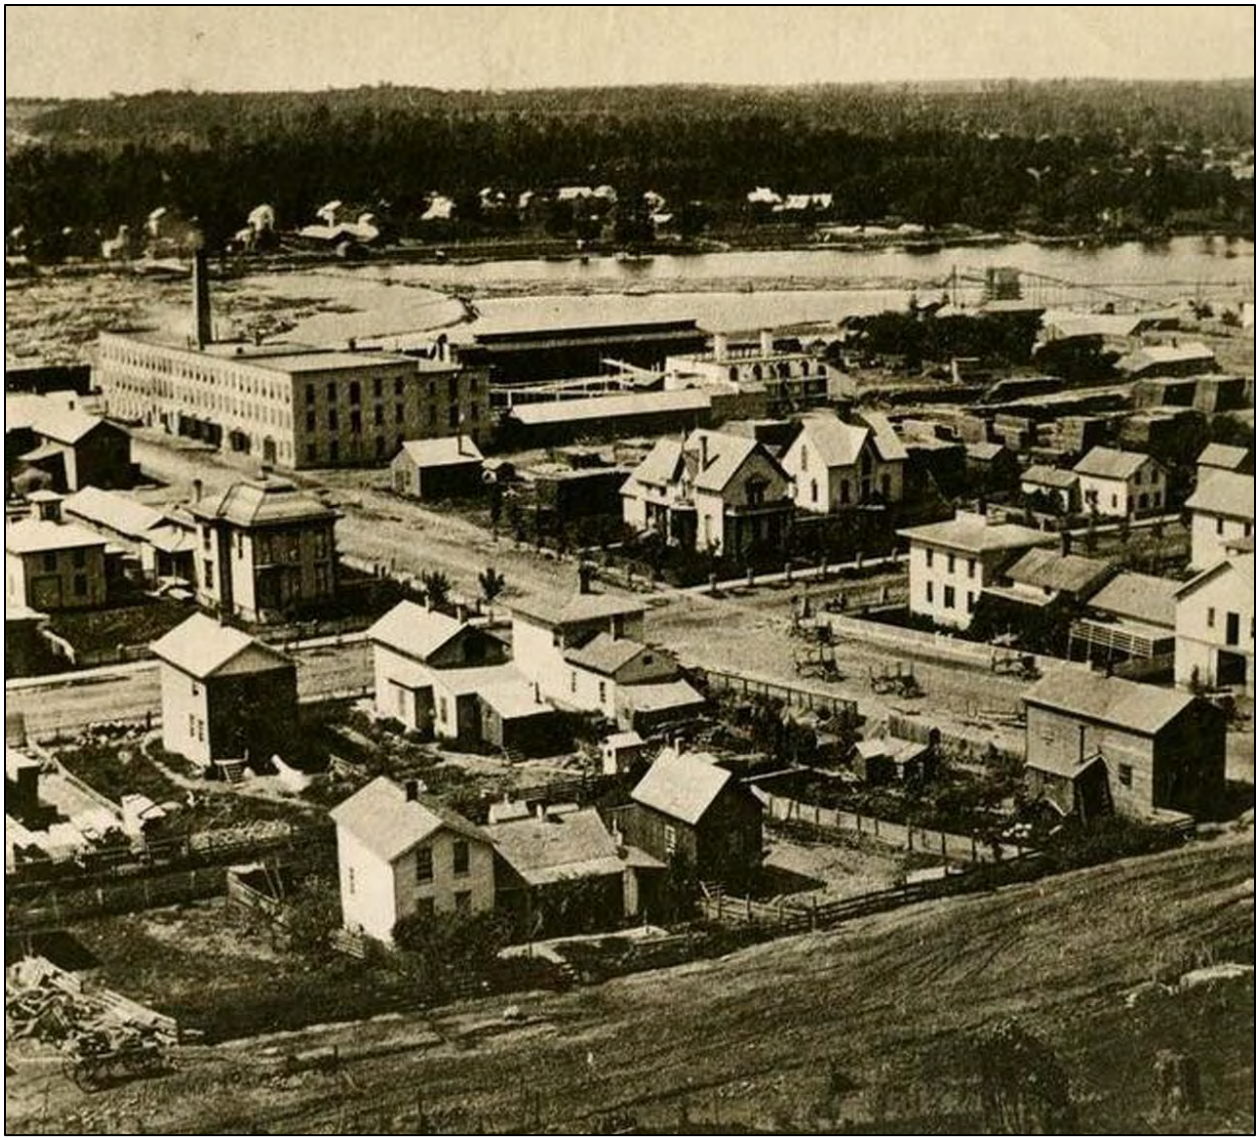

Figure 2.0-2: View of Grand Rapids in 1865 with the 1849 Horseshoe Dam in the Background (GRPL)

In 1866, the West Side Water Power Association began construction on the West Side Canal. Through an agreement with the East Side Water Power Company, the water rights would be split between the two companies, and a new, more permanent timber crib dam would be constructed across the river at Fourth Street that would serve both canals. This was known as the water power dam, or Fourth Street Dam (Figure 2.0-3). It was located a few blocks south of the earlier horseshoe dam, which remained in place until at least 1878 but was gone by 1888 (GRCARC 1873, 2019; Sanborn Map Company 1888). The Fourth Street Dam was later known as the Sixth Street Dam (Robinson et al. 2020).

In the early twentieth century, Grand Rapids experienced a series of disastrous floods. The first of these in 1904 damaged a 150-foot section of the Fourth Street Dam. At that time, it was suggested that a concrete dam replace the 1866 timber crib dam, although it appears that the dam was simply repaired (*Grand Rapids Herald* 1904). The city hired Lyman E. Cooley, an engineer from Chicago, to make recommendations regarding flood control and improving water power. Cooley proposed in 1904 that flood

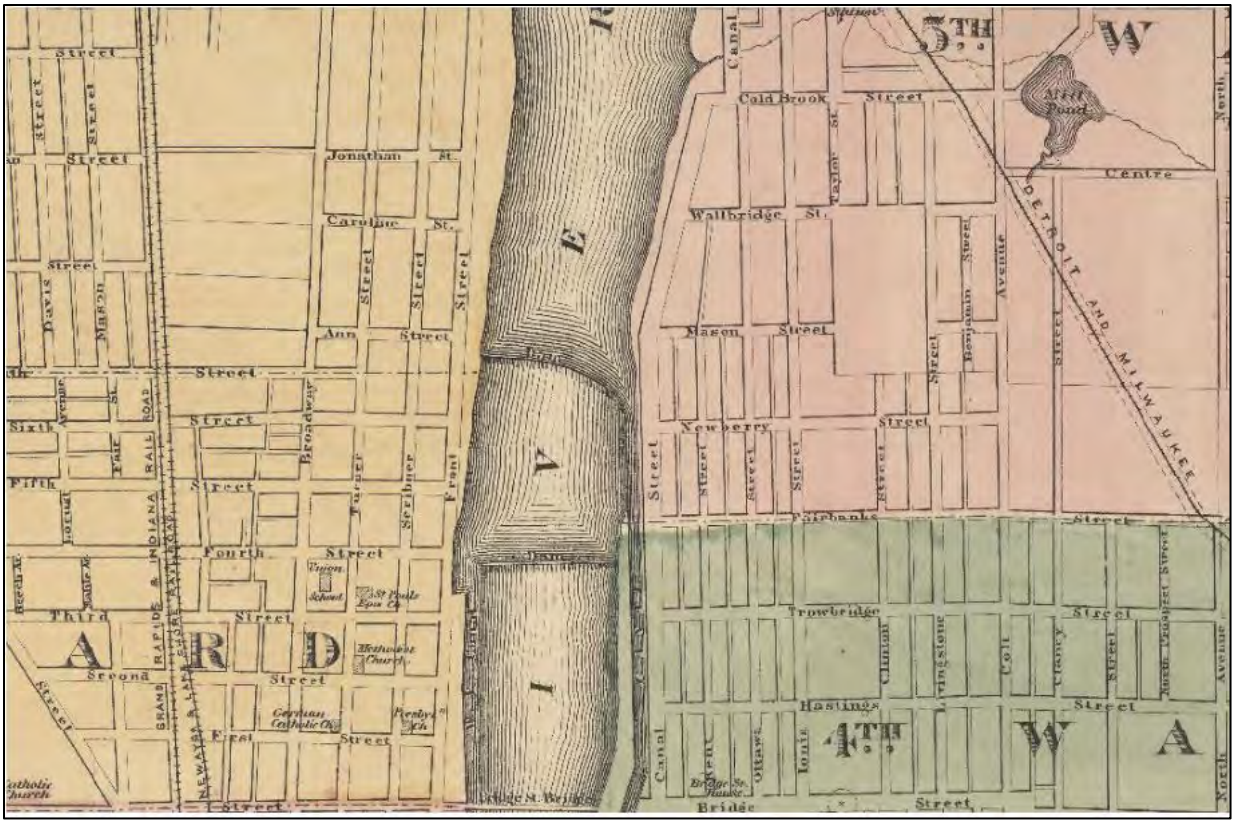

Figure 2.0-3: Map of Grand Rapids in 1873 Showing the 1866 Fourth Street Dam, the 1849 Horseshoe Dam, and the East and West Side Canals (GRCARC)

walls be constructed through the city, and work on these was begun soon after (Figure 2.0-4; Lydens 1966:122). In 1909, Cooley proposed that a new dam be constructed 300 feet north of Bridge Street. This dam was apparently not constructed (Biolchini 2019; Cooley 1909; Forist and Gleisner 2015).

In 1915, another major flood took out a 100-foot section of the western part of the Fourth Street Dam. Plans were proposed for the repair of the dam, with both a timber crib replacement and an upgrade to concrete being considered. The design of the concrete section is nearly identical to the plans later used for the Beautification Dams downstream. It appears from later plans that the damaged section was replaced with concrete, and the remaining timber crib section was replaced in 1926 when the beautification project was undertaken (GRCARC 2019).

The idea of a series of low-head dams on the Grand River in order to maintain water in the river bed and prevent the accumulation of trash and brush in the river was proposed by city planner Harland Bartholomew, whose firm was hired by the Grand Rapids Planning Department in the early 1920s to develop a master plan for the city (GRPL 2017). The diversion of water for the East and West Side Canals and city water works had resulted in the river often lacking a constant flow, resulting in the accumulation of trash and brush in the riverbed (Figure 2.0-5). The low-head dams would maintain the flow of the river and would “add greatly to the appearance and provide ample water surface for boating,” according to Bartholomew (Bartholomew 1925; Biolchini 2019; GRPM ca. 1926). An appropriation was approved for the beautification project in March 1926, but it was not until May 1927 that a bid of $24,112 was accepted from a Grand Rapids firm for the construction, with an expected completion date of

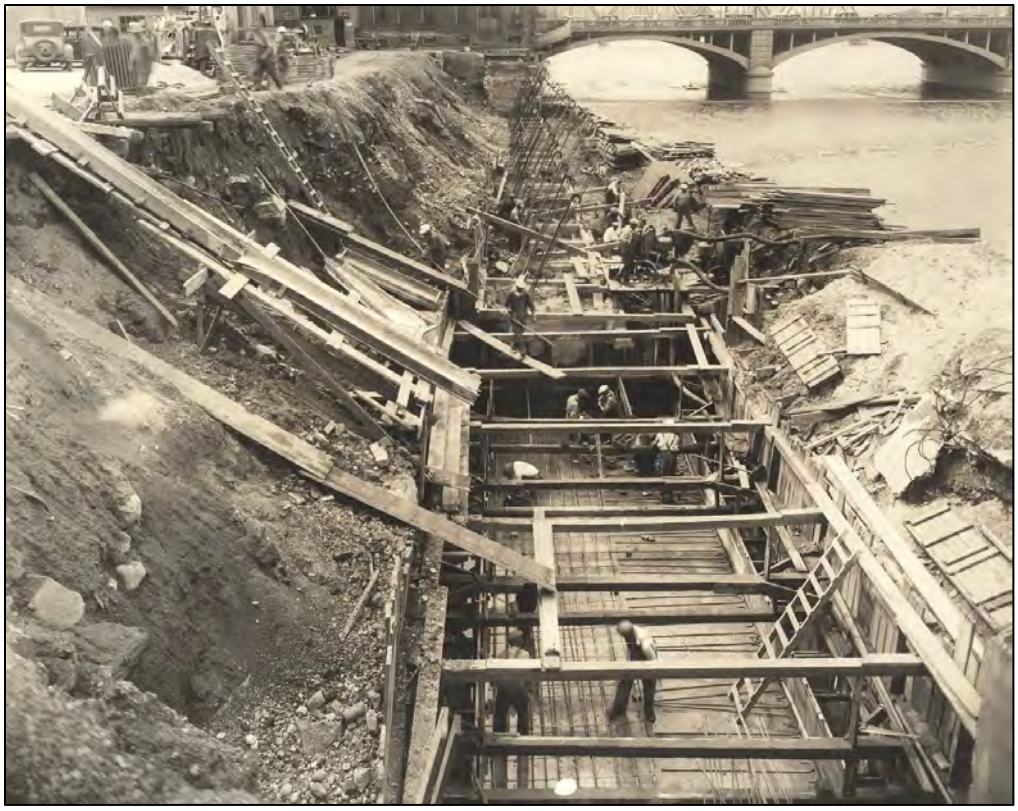

Figure 2.0-4: Construction of Flood Walls on the East Side of the River above the Pearl Street Bridge (GRCARC)

Figure 2.0-5: View of Downtown and the River Showing Brush Growing in the Riverbed Downstream of the Fourth Street Dam (GRPM)

January 1, 1928. The *Grand Rapids Press* praised the city for approving the plan, which would help the river "take on some of the beauty which existed before drought and the west side canal removed all liquid attractions" (*Grand Rapids Press* 1927a, 1927b).

The dams were constructed by diverting water using a coffer dam, leaving the riverbed dry (Figure 2.0-6) (*Grand Rapids Herald* 1927). They were completed by January 2, 1928, when a report of the Engineers' Office noted that it had overseen the placement of the dams at a cost of $37,000. In April 1928, the mayor remarked that the dams had "improved the appearance of the river 100 percent." In July 1928, the *Grand Rapids Press* remarked, "By expenditure on a series of carefully placed dams Grand Rapids has succeeded, without increasing its flood hazard in restoring some of the beauty of Grand river between the main dam at Fourth street and a point two or three hundred feet north of Pearl Street bridge" (*Grand Rapids Press* 1928a, 1928b).

The dams have remained in place to the present, with no known significant changes. The purposes of the dam construction project were well realized, as the water level was maintained, and public and private development became more focused on the river in the twentieth century. Numerous parks and public and private attractions have been established on both sides of the river, including the Gerald R. Ford Presidential Museum, Grand Rapids Public Museum, the Civic Auditorium (now part of the DeVos Place Convention Center), Ah-Nab-Awen Park, and Sixth Street Park.

Details related to the conception, design and construction of the Beautification Dams, as well as their place within the context of city planning in general and the work of Harland Bartholomew in particular, are discussed in greater detail in Section 4.

3. METHODS

3.1 Survey Methods

The current investigation was prompted by a request from the MI SHPO for additional information about the four low-head dams and their historical context to assist in a determination of eligibility. In a comment letter dated December 17, 2020, MI SHPO requested survey information about the nature and condition of the dams and a discussion of their potential NRHP eligibility within a proper historical context.

Because of accessibility issues due to the COVID-19 pandemic and the fact that the dams are currently covered by water, ERM architectural historians undertook a remote survey of the properties based on historical plans and historical and current photographs from a variety of sources including the GRCARC, GRWW, GRPL, Google Earth, and previous site visits. The photographs were used to record the structures' overall appearance and details. Topographic maps and aerial photographs were used to record the relationship of the structures to each other and the surrounding landscape features and infrastructure.

A Michigan State Architectural Properties Identification Form was completed as part of the recordation process, which is attached in Appendix A.

3.2 Documentary Research

In order to assess the significance of the dams, ERM collected information from knowledgeable experts in local history, city planning, and historical public works. ERM conducted online research to identify historic themes, events, and patterns important in the development of local, regional, and national significance. Local government records and information provided by knowledgeable local organizations also were examined to establish a context for the development of the water control systems in Grand Rapids, as well as specific details relating to the system as built and as it exists today. Documents, maps, and photographs were collected from the GRCARC, the GRPM, the GRPL, and the GRHC.

3.3 NRHP and Effects Evaluation

The four dams were evaluated with respect to their eligibility for listing on the NRHP using published guidance from the National Park Service. According to 36 CFR 60.4 (Andrus and Shrimpton 2002), cultural resources eligible for listing on the NRHP are defined as buildings, structures, objects, sites, and districts that have "integrity" and that meet one or more of the criteria outlined below. Criterion D is typically relevant to archaeological sites. Historic resources are generally evaluated in relation to Criteria A, B, and C. Criterion C is typically applicable to architectural resources but also may be relevant in the case of resources that are associated with landscape architecture (like cemeteries or battlefields) or engineering (like dams, bridges, railroads, and mines).

- Criterion A (Event). Association with one or more events that have made a significant contribution to the broad patterns of national, state, or local history
- Criterion B (Person). Association with the lives of persons significant in the past
- Criterion C (Design/Construction). Embodiment of distinctive characteristics of a type, period, or method of construction; or representation of the work of a master; or possession of high artistic values; or representation of a significant and distinguishable entity whose components may lack individual distinction
- Criterion D (Information Potential). Properties that yield, or are likely to yield, information important in prehistory or history. Criterion D is most often (but not exclusively) associated with archaeological resources. To be considered eligible under Criterion D, sites must be associated with specific or

general patterns in the development of the region. Therefore, sites become significant when they are seen within the larger framework of local or regional development.

"Integrity" is perhaps the paramount qualification of NRHP eligibility, and can be related to any or all of the following (Andrus and Shrimpton 2002):

- Location: the place where the historic property (or properties) was/were constructed or where the historic event(s) occurred
- Design: the combination of elements that create the form, plan, space, structure, and style of a property (or properties)
- Setting: the physical environment of the historic property (or properties)
- Materials: the physical elements that were combined to create the property (or properties) during the associated period of significance
- Workmanship: the physical evidence of the crafts of a particular culture or people during any given period in history or prehistory
- Feeling: the property's (or properties') expression of the aesthetic or historic sense of the period of significance
- Association: the direct link between the important historic event(s) or person(s) and the historic property (or properties).

The four dams were evaluated in relation to these criteria and attributes, and then the criteria of adverse effect were applied for the proposed undertaking in accordance with ACHP regulations at 36 CFR 800.5. Specifically,

> An adverse effect is found when an undertaking may alter, directly or indirectly, any of the characteristics of a historic property that qualify the property for inclusion in the National Register in a manner that would diminish the integrity of the property's location, design, setting, materials, workmanship, feeling, or association. Consideration shall be given to all qualifying characteristics of a historic property, including those that may have been identified subsequent to the original evaluation of the property's eligibility for the National Register. Adverse effects may include reasonably foreseeable effects caused by the undertaking that may occur later in time, be farther removed in distance or be cumulative.

4. SURVEY RESULTS

This section presents the findings of the historic architectural investigation carried out for the Project. One resource, consisting of four low-head dams in the Grand River at Grand Rapids, known as Beautification Dams, was evaluated as part of the Section 106 review for the Project. The dams would be removed as part of the Project, and thus would be subject to direct effects from the Project.

4.1 Previous Investigations

A literature review of previously recorded resources determined that the Beautification Dams had not been previously recorded as historic resources. An Architectural Properties Identification Form was completed as part of the current investigations (Appendix A).

4.2 Current Survey Findings

The Beautification Dams consist of four low-head concrete dams ranging from 1.5 to 3 feet in height and approximately 425 to 440 feet in length, located in the Grand River between the Interstate 196 Bridge and the Pearl Street Bridge. The four dams together constitute the evaluated resource, and are collectively referred to as the Beautification Dams in the Grand River. They are recommended eligible for the NRHP and are summarized in Table 4.2-1. A view of each dam is shown in Figures 4.2-1 through 4.2-4.

Table 4.2-1: Summary of Beautification Dams in the Grand River

Number	Location	Length*	Height†
Dam #1	135–155 feet north of the center of the Bridge Street Bridge	437 feet	3 feet
Dam #2	148–175 feet south of the center of the Bridge Street Bridge	440 feet	1.5 feet
Dam #3	336–373 feet north of the center of the Gillette Pedestrian Bridge (Interurban Bridge)	440 feet	2 feet
Dam #4	85 feet north of the center of the Pearl Street Bridge	425 feet	1.5 feet

* Estimated length based on aerial photographs

4.2.1 Beautification Dams History

Low-head or low-stage dams typically run the width of a river or stream and allow the water flow to pass over all or most of its length. They can be as high as 15 feet, but are more commonly just a few feet in height. These types of dams are common throughout the United States and are usually constructed to raise the water level for civic, industrial, or agricultural use. They also enhance recreational opportunities. Many low-head dams were constructed across the U.S. in the eighteenth and nineteenth centuries to power gristmills and small industries (Tschantz and Wright 2011:8).

The use of low-head dams for beautification and recreation, rather than commercial and industrial uses, coincided with the emergence of city planning as a professional pursuit in the early twentieth century, and a shift in public attitudes toward the environment and the revitalization of urban areas through public improvement projects and regulatory policy (Hill 2000:153). Harland Bartholomew was a prominent city planner from the 1920s to the 1980s, known for advocating for zoning laws and creating the concept of the “City Efficient.” His firm, Harland Bartholomew & Associates (HB&A) developed more than 500 city plans and more than 300 zoning proposals for cities in the U.S. and internationally (Barone 2018:438).

Bartholomew began working on a plan for Grand Rapids as early as 1921 (GRPL 2017). His plan for Grand Rapids was based on similar principles to those he applied in other cities, both large and small. The plans were based on zoning, a concept that was being recognized by city leaders as the most efficient way to maintain property values and grow their cities in a controlled manner. Bartholomew’s zoning classes were based on variations on three factors: use, building height, and lot size. Industrial uses were zoned to the outskirts of the city, along rail lines and waterways, while the downtown area was designated for commercial use. Planning firms worked with city planning commissions to develop a plan that the commission could promote to city officials, civic groups, and business leaders. The planning commissions also worked to build public support for the plans. The goal was to get buy-in from a variety of interests in the city by highlighting the economic advantages that would accrue from a comprehensive zoning plan. In Grand Rapids, the City Planning Commission presented their early planning work at a municipal fair called “City Show” in 1920 (Moskowitz 1998:308–309).

Bartholomew produced a number of documents for the City of Grand Rapids between 1921 and 1927. His overall vision was presented to the public in 1924 through the *Grand Rapids Press* (1924a), which published a rendering of the “Future Grand Rapids” produced by Bartholomew (Figure 4.2-5). The Grand River occupied the prominent spot in the oblique aerial view and was flanked by a tree-lined esplanade on the east bank and a park with trees, open spaces, and walkways on the west bank. The bridge at the bottom of the drawing is the Bridge Street Bridge, with the next two bridges being the interurban rail bridge (Gillette Pedestrian Bridge) and the Pearl Street Bridge. No dams are evident in the view, but the river is full from bank to bank, with no obstructions. Eventually, the esplanade along the river was constructed in the form of the Riveredge Trail, and parks were established along the west side of the river, as envisioned in the plan. The changes proposed in the plan, including a “beautiful river front,” were praised by the paper as “outstanding” (Grand River Press 1924b).

Bartholomew’s City Plan for Grand Rapids included a section on riverfront improvement (Bartholomew 1925:100–103). He stated that the river was the city’s “raison d’etre,” but had fallen into insignificance in the commercial age. However, Bartholomew maintained that opportunities for development were available, and that the city should purchase as much of the riverfront property as possible. The flood walls in place along portions of the river were seen as a positive influence that would permit linear parks adjacent to the river. He recommended the construction of additional walls and the reclaiming land adjacent to the east side of the river that was occupied by the East Side Canal and constructing a road alongside the river. This would separate the buildings from the riverside docks and encourage more aesthetic architecture. The improvements would not interfere with the commercial or industrial activities of

the city, because the river no longer had value to those interests. The plan for the river was plainly laid out, including improving the appearance below the existing 6th Street dam:

> Grand Rapids must complete its flood wall as a protective measure. It would seem that this work would offer the best opportunity to carry out a more thorough riverfront improvement program. Not only should the banks be improved by the use of wall, terraces, small parks and plazas, but the appearance of the river below the dam should be improved. During the dry seasons certain stretches of the rapids have the appearance of an abandoned stone quarry overgrown with weeds and littered with tin cans, crates and rubbish. Several low-stage dams could be constructed at intervals which would maintain water constantly in the river. This would add greatly to the appearance and provide ample water surface for boating [Bartholomew 1925:102].

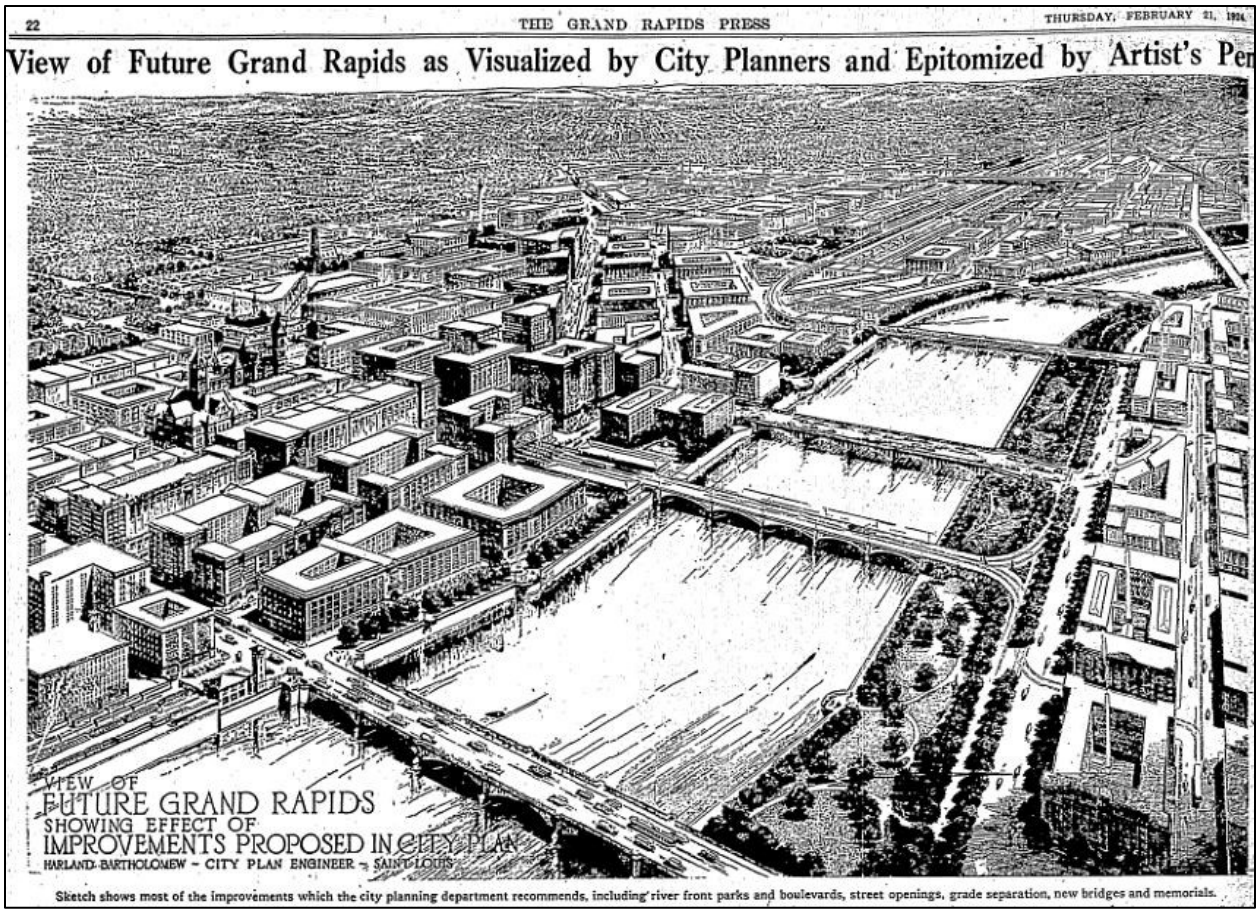

Figure 4.2-5: Artist Rendition of Harland Bartholomew's City Plan (1924)

In October 1925, the city reached an agreement with the Consumers Power Company (the former West Side Water Power Association) and the East Side Power Company to purchase the rights to the East Side Canal, which would be closed to form a sewer and a riverside park. The city had held an option on the rights to the canal for some time, and it appears that the acquisition of the property was part of the effort to carry out the plans for beautification of the river. The agreement stipulated that the city "reserved perpetual right to sufficient water for all city purposes, and that "sufficient water must be kept running over

the large dam to keep a series of smaller dams filled the year around" (*Grand Rapids Press* 1925). The story in the *Grand Rapids Press* stated that the city would keep the river clean, and "To this end it has secured the necessary options for construction of three dams, one just north of Bridge-st., one just south of Bridge-st., and third just north of Pearl-st., calculated to hold enough water to hide the ugly bottom, now strewn with all manner of debris and overgrown with weeds." According to the article, the "pretentious program of beautification, as sketched by Harland Bartholomew of St. Louis, city planning expert responsible for Grand Rapids' zoning ordinance, now approaches a step nearer realization."

The value of improving the river both economically and aesthetically was not lost on observers, even in the planning stages. The *Grand Rapids Press* noted of the plan in 1925 that, "Advantage will be taken of the open sloping west bank, which now is a mass of weeds, and a modest program of landscaping and care is expected to do wonders." The acquisition of the canal land allowed for a reorganized street plan and the availability of valuable land. "When this wilderness of rubbish, old iron and decrepit buildings has been cleared away the increased value of the property, according to the analysis of [assistant to the city's consulting engineer] Mr. Tenlloor, will have justified the trouble, and the city will be rid of perhaps its greatest fire menace" (*Grand Rapids Press* 1925).

The original plan apparently included five dams, but only four were constructed due to water rights of the last user of the West Side Canal for a water wheel (*Grand Rapids Press* 1927a, 1928b). The city appropriated $7,500 in March of 1926 for "…beautification of Grand River through the erection of dams intended to create a greater depth of water inside the city limits" (*Grand Rapids Press* 1926). However, it was not until May of 1927 that a bid was accepted for the project. The $24,000 bid of Peninsular Construction Company of Grand Rapids was over the city's estimate for the work, but was less than the only other bid received. The plans at that time were for the dams to be constructed of concrete and approximately 470 feet long. The dams were to be located 100 feet north of Bridge Street, 36 feet south of Bridge Street, at Brumrich Street, 50 feet north of Pearl Street, and 35 feet south of Pearl Street (*Grand Rapids Press* 1927a). The locations given approximate the final placements, which are detailed in Table 4.2-1.

Profile plans of the dams are shown in Figure 4.2-6 (GRCARC ca. 1927). It is not clear if the dams were built to these exact specifications, as no as-built drawings have been located. The profiles indicate that Dam #1 would have a height of 3 feet, Dam #2 and Dam #4 would be 1.5 feet high, and Dam #3 and Dam #5 would each be 2 feet high. Dam #5 was eventually dropped from the plan. A profile map of the river made in 1928 indicates that the actual dams were lower (GRCARC 1928). Current elevations taken across the dams show irregular heights across the width of the dams and only about a 1–1.5-foot drop between them. This may be due to erosion of the tops of the dam as a result of water scouring. The profiles in Figure 4.2-6 show a typical low-head concrete dam shape that has a slightly sloping upstream face with a beveled cap and a ramp-like downstream face to break the fall of the water. Each dam would have a flap or drain valve at the base. Figure 4.2-7 shows the profile of the dams after construction, which is consistent with the plans. The valve appears to have been constructed as a gated opening rather than an outlet in the base of the dam, as can be seen in Figure 4.2-8.

Work on the coffer dam to divert the river during construction began by July 1927 (*Grand Rapids Herald* 1927). As noted above, the dams were completed on schedule by January 1, 1928, although the $37,000 cost was considerably more than the $24,000 bid. Figure 4.2-9 shows Dam #1 after construction, looking north, with the Sixth Street Dam in the background.

Figure 4.2-9: Dam #1 after Construction, 1927, with Water Flowing in the River Bed (GRCARC)

4.2.2 Beautification Dams: Architectural Description and Evaluation

The Beautification Dams in the Grand River are four low-head, concrete dams that run the width of the river in downtown Grand Rapids. They vary in height from 1.5 to 3 feet, and in length from approximately 425 feet to 440 feet. They are anchored in bedrock to a depth of approximately 1 foot. Historical drawings and photographs indicate that a gated opening was located in each dam, but the nature and location of these openings in the current dams is not clear due to the dams being obscured by water. The dams have the same basic profile as shown in Figures 4.2-6 and 4.2-7. The form and construction technique is typical of low-head dams constructed throughout the United States during the period.

NRHP Evaluation: ERM recommends that the Beautification Dams in Grand River are potentially eligible for the NRHP under Criterion A for their association with events important to the history of Grand Rapids. The dams reflect efforts in the early twentieth century to improve the city through planning, zoning, and public works projects. The result was a shift in the orientation of the downtown area to embrace the river as an attraction for enjoyment and recreation. Parks and trails were established along the banks, and new buildings were constructed with an emphasis on attractive architecture that encouraged public use of the surrounding spaces. ERM recommends that the dams are also significant under Criterion B for their association with Harland Bartholomew, one of the most influential city planners of the twentieth century.

Beginning in St. Louis in 1916, Bartholomew and his firm developed plans for hundreds of cities, influencing zoning decisions and promoting urban renewal and beautification. Bartholomew's plan for Grand Rapids specifically called for the installation of the dams, which consequently influenced the development of the downtown area in the way in which he intended. Although the Beautification Dams retain sufficient architectural integrity to convey the resources' historical significance, their design is utilitarian and common to contemporary structures across the country. As a result, they do not represent exceptional design or engineering and do not constitute an outstanding example of architecture associated with historic water control features. Therefore, ERM recommends the Beautification Dams in Grand River are not potentially eligible for the NRHP under Criterion C. For similar reasons, ERM recommends that the dams are not likely to yield information important to history and are thus not potentially eligible under Criterion D.

Assessment of Effects: The function of the Beautification Dams would not be retained as a result of their removal, although the Project is intended to restore the beauty of the original rapids that once characterized the river. The placid, quiet waters created by the dams would be replaced by faster moving water that would create a different atmosphere than that which characterized the river between 1927 and the present. Although the goal of the Project, in part, is similar to that of the 1925 Bartholomew plan in making the river attractive for expanded recreation and use, the nature of the experience for those using the river space would be different from that intended by Bartholomew. Therefore, it is ERM's opinion that the proposed removal of the dams would compromise the character-defining features of the dams that make them historically significant, and the action would constitute an adverse effect.

5. CONCLUSION AND RECOMMENDATIONS

ERM conducted an evaluation of the NRHP eligibility of four low-head dams in the Grand River in Grand Rapids, which would be affected by the Grand Rapids Whitewater Project. With the support of the City of Grand Rapids and GRWW, ERM prepared this report evaluating whether the beautification dams constructed along the Grand River in the early twentieth century are potentially eligible for the NRHP, and if so, whether removal of the dams as part of the Project would result in adverse effects to these cultural resources. The findings of the current study are intended to support the Section 106 review of the proposed undertaking, which is subject to funding by the NRCS.

Based on the information gathered and presented here, ERM recommends that the four low-head dams, referred to as the Beautification Dams in Grand River, are potentially eligible for the NRHP. The dams meet the requirements for listing under Criterion A for their role in the emergence of city planning and the development of the riverfront as a focal point of downtown development in Grand Rapids, and under Criterion B for their association with city planner Harland Bartholomew, whose ideas on city beautification influenced the development of Grand Rapids during the twentieth century. Although the Beautification Dams retain sufficient architectural integrity to convey their historical significance, their design is utilitarian and common to contemporary structures across the country, and is not likely to yield information important to history. Therefore, ERM recommends that the Beautification Dams are not potentially eligible for the NRHP under Criteria C and D.

The function of the Beautification Dams to maintain water levels across the width of the Grand River would not be retained as a result of their removal. Although the goal of the Project, in part, is similar to that of the 1925 Bartholomew plan in making the river attractive for expanded recreation and use, the nature of the experience for those using the river space would be different from that intended by Bartholomew. Therefore, it is ERM's opinion that the proposed removal of the dams would compromise the character-defining features of the dams that make them historically significant, and the action constitutes an adverse effect. The Project plan as currently proposed requires removal of all of the dams and does not allow for avoidance or minimization of adverse effects. It is ERM's recommendation that, should MI SHPO concur with this assessment, a plan be developed to mitigate the adverse effects of the Project.

For SHPO Use Only	SHPO Concurrence?: Y / N	Date:

Narrative Architectural Description

Provide a detailed description of the property, including all character-defining features and any accessory resources. This is required for all properties.

The Beautification Dams in the Grand River are four low-head, concrete dams that run the width of the river in downtown Grand Rapids. They vary in height from 3 feet to 1.5 feet, and in length from approximately 425 feet to 440 feet. They are anchored in bedrock to a depth of approximately 1 foot. The only feature of the dams is an opening, presumably for flow and debris control. The dams have the same basic profile. The form and construction technique is typical of low-head dams constructed throughout the United States during the period.

History of the Resource

Provide information on previous owners, land use(s), and construction and alteration dates in a narrative format. This is required for all intensive level surveys, NRPQs, and nominations, and recommended for other identification efforts.

(see Figures at end of form)

Low-head or low-stage dams typically run the width of a river or stream and allow the water flow to pass over all or most of its length. They can be as high as 15 feet, but are more commonly just a few feet in height. These types of dams are common throughout the United States and are usually constructed to raise the water level for civic, industrial, or agricultural use. They also enhance recreational opportunities. Many low-head dams were constructed across the U.S. in the eighteenth and nineteenth centuries to power gristmills and small industries (Tschantz and Wright 2011:8).

The use of low-head dams for beautification and recreation, rather than commercial and industrial uses in the early twentieth century coincided with the emergence of city planning as a professional pursuit, and a shift in public attitudes toward the environment and the revitalization of urban areas through public improvement projects and regulatory policy (Hill 2000:153). Harland Bartholomew was a prominent city planner from the 1920s to the 1980s, known for advocating for zoning laws and creating the concept of the “City Efficient.” His firm, Harland Bartholomew & Associates (HB&A) developed more than 500 city plans and more than 300 zoning proposals for cities in the U.S. and internationally, making it likely the largest city planning firm in the country (Barone 2018:438).

Bartholomew began working on a plan for Grand Rapids as early as 1921 (GRPL 2017). His plan for Grand Rapids was based on similar principles to those he applied in other cities, both large and small. The plans were based on zoning, a concept that was being recognized by city leaders as the most efficient way to maintain property values and grow their cities in a controlled manner. Bartholomew’s zoning classes were based on variations on three factors: use, building height, and lot size. Industrial uses were zoned to the outskirts of the city, along rail lines and waterways, while the downtown area was designated for commercial use. Planning firms worked with city planning commissions to develop a plan that the commission could sell to city officials, civic groups, and business leaders. The planning commissions also worked to build public support for the plans. The goal was to get buy-in from a variety of interests in the city by highlighting the economic advantages that would accrue from a comprehensive zoning plan. In Grand Rapids, the City Planning Commission presented their early planning work at a municipal fair called “City Show” in 1920 (Moskowitz 1998:308–309).

Bartholomew produced a number of documents for the City of Grand Rapids between 1921 and 1927. His overall vision was presented to the public in 1924 through the *Grand Rapids Press* (1924a), which published a rendering of the “Future Grand Rapids” produced by Bartholomew (Figure 1). The Grand River occupied the prominent spot in the oblique aerial view and was flanked by a tree-lined esplanade on the east bank and a park with trees, open spaces, and walkways on the west bank. The bridge at the bottom of the drawing is the Bridge Street Bridge, with the next two bridges being the interurban rail bridge (Gillette Pedestrian Bridge) and the Pearl Street Bridge. No dams are evident in the view, but the river is full from bank to bank, with no obstructions. Eventually, the esplanade

along the river was constructed in the form of the Riveredge Trail, and parks were established along the west side of the river, as envisioned in the plan. The changes proposed in the plan, including a "beautiful river front," were praised by the paper as "outstanding" (Grand River Press 1924b)

Bartholomew's City Plan for Grand Rapids included a section on riverfront improvement (Bartholomew 1925:100–103). He stated that the river was the city's "raison d'etre," but had fallen into insignificance in the commercial age. However, Bartholomew maintained that opportunities for development were available, and that the city should purchase as much of the riverfront property as possible. The flood walls in place along the river were seen as a positive influence that would permit linear parks adjacent to the river. He recommended reclaiming land adjacent to the east side of the river that was occupied by the East Side Canal and constructing a road alongside the river. This would separate the buildings from the riverside docks and encourage more aesthetic architecture. The improvements would not interfere with the commercial or industrial activities of the city, because the river no longer had value to those interests. The plan for the river was plainly laid out:

> Grand Rapids must complete its flood wall as a protective measure. It would seem that this work would offer the best opportunity to carry out a more thorough riverfront improvement program. Not only should the banks be improved by the use of wall, terraces, small parks and plazas, but the appearance of the river below the dam should be improved. During the dry seasons certain stretches of the rapids have the appearance of an abandoned stone quarry overgrown with weeds and littered with tin cans, crates and rubbish. Several low-stage dams could be constructed at intervals which would maintain water constantly in the river. This would add greatly to the appearance and provide ample water surface for boating. (Bartholomew 1925:102)

In October 1925, the city reached an agreement with the Consumers Power Company (the former West Side Water Power Association) and the East Side Power Company to purchase the rights to the East Side Canal, which would be closed to form a sewer and a riverside park. The city had held an option on the rights to the canal for some time, and it appears that the acquisition of the property was part of the effort to carry out the plans for beautification of the river. The agreement stipulated that the city "reserved perpetual right to sufficient water for all city purposes,"…and that "sufficient water must be kept running over the large dam to keep a series of smaller dams filled the year around" (*Grand Rapids Press* 1925). The story in the *Grand Rapids Press* stated that the city would keep river clean, and "To this end it has secured the necessary options for construction of three dams, one just north of Bridge-st., one just south of Bridge-st., and third just north of Pearl-st., calculated to hold enough water to hide the ugly bottom, now strewn with all manner of debris and overgrown with weeds." According to the article, the "pretentious program of beautification, as sketched by Harland Bartholomew of St. Louis, city planning expert responsible for Grand Rapids' zoning ordinance, now approaches a step nearer realization."

The value of improving the river, both economically and aesthetically was not lost on observers, even in the planning stages. The *Grand Rapids Press* noted of the plan in 1925 that, "Advantage will be taken of the open sloping west bank, which now is a mass of weeds, and a modest program of landscaping and care is expected to do wonders." The acquisition of the canal land allowed for a reorganized street plan and the availability of valuable land. "When this wilderness of rubbish, old iron and decrepit buildings has been cleared away the increased value of the property, according to the analysis of [assistant to the city's consulting engineer] Mr. Tenlloor, will have justified the trouble, and the city will be rid of perhaps its greatest fire menace" (*Grand Rapids Press* 1925).

The original plan apparently included five dams, but only four were constructed due to water rights of the last user of the West Side Canal for a water wheel (*Grand Rapids Press* 1927a, 1928b). The city appropriated $7,500 in March of 1926 for "…beautification of Grand River through the erection of dams intended to create a greater depth of water inside the city limits" (Grand Rapids Press 1926). However, it was not until May of 1927 that a bid was accepted for the project. The $24,000 bid of Peninsular Construction Company of Grand Rapids was over the city's estimate for the work, but was less than the only other bid received. The plans at that time were for the dams to be constructed of concrete and approximately 470 feet long. The dams were to be located 100 feet north of Bridge Street, 36 feet south of Bridge Street, at Brumrich Street, 50 feet north of Pearl Street, and 35 feet south of Pearl Street (*Grand Rapids Press* 1927a).

Profiles plans of the dams are shown in Figure 2 (GRCARC ca. 1927). It is not clear if the dams were built to these

exact specifications, as no as-built drawings have been located. The profiles indicate that Dam #1 would have a height of 3 feet, Dam #2 and Dam #4 would be 1.5 feet high, and Dam #3 and Dam #5 would each be 2 feet high. Dam #5 was eventually dropped from the plan. A profile map of the river made in 1928 indicates that the actual dams were lower (GRCARC 1928). Current elevations taken across the dams show irregular heights across the width of the dams and only about a 1–1.5-foot drop between them. This may be due to erosion of the tops of the dam as a result of water scouring. The profiles in Figure 2 show a typical low-head concrete dam shape that has a slightly sloping upstream face with a beveled cap and a ramp-like downstream face to break the fall of the water. Each dam would have a flap or drain valve at the base. Figure 3 shows the profile of the dams after construction, which is consistent with the plans. The valve appears to have been constructed as a gated opening rather than an outlet in the base of the dam, as can be seen in Figure 4.

Work on the coffer dam to divert the river during construction began by July 1927 (*Grand Rapids Herald* 1927). As noted above, the dams were completed on schedule by January 1, 1928, although the $37,000 cost was considerably more than the $24,000 bid. Figure 5 shows Dam #1 after construction, looking north, with the Sixth Street Dam in the background.

Statement of Significance/Recommendation of Eligibility

Provide a detailed explanation of the property's eligibility for the National Register. Include an evaluation under at least one of the four National Register Criteria and one Area of Significance. Include a discussion of the seven aspects of integrity, and make a recommendation about eligibility. This is required for all properties.

The Beautification Dams retain integrity of location, as they have not moved from their original location. In addition, the associated bridges and the river have remained unchanged, and most of the buildings surrounding the dams are original to the construction of the dams, which means the dams still retain integrity of setting. The Beautification Dams do retain their design and material integrity as no alterations to the utilitarian structures are known. Furthermore, the dams retain integrity of workmanship and association as a structure that conveys the craftsmanship of a utilitarian design tied to water control and public works improvement projects. Finally, the Beautification Dams retain integrity of feeling when viewed as a whole, with the river and surrounding bridges. For these reasons, ERM recommends that the Beautification Dams in Grand River are potentially eligible for the NRHP under Criterion A for their association with events important to the history of Grand Rapids. The dams reflect efforts in the early twentieth century to improve the city through planning, zoning, and public works projects. The result was a shift in the orientation of the downtown area to embrace the river as an attraction for enjoyment and recreation. Parks and trails were established along the banks, and new buildings were constructed with an emphasis on attractive architecture that encouraged public use of the surrounding spaces. ERM recommends that the dams are also significant under Criterion B for their association with Harland Bartholomew, one of the most influential city planners of the twentieth century. Beginning in St. Louis in 1916, Bartholomew and his firm developed plans for hundreds of cities, influencing zoning decisions and promoting urban renewal and beautification. Bartholomew's plan for Grand Rapids specifically called for the installation of the dams, which consequently influenced the development of the downtown area in the way in which he intended. Although the Beautification Dams retain sufficient architectural integrity to convey the resources' historical significance, their design is utilitarian and common to contemporary structures across the country. As a result, they do not represent exceptional design or engineering and do not constitute an outstanding example of architecture associated with historic water control features. Therefore, ERM recommends the Beautification Dams in Grand River are not potentially eligible for the NRHP under Criterion C. For similar reasons, ERM recommends that the dams are not likely to yield information important to history and are thus not potentially eligible under Criterion D.

APPENDIX B RESUMES

Jeffrey L. Holland

Historian

Mr. Holland has over 30 years of experience on Cultural Resources Management projects throughout the eastern United States, the Midwest, and Texas. He has conducted historical research and documentation for National Register properties and districts, HABS/HAER recordation, Assessments of Effects reports, and cultural resources survey, testing, and data recovery projects. He has also authored popular histories for major industrial facilities and summaries of archaeological projects for public education. Mr. Holland's specialties include slavery, African American history, nineteenth century agriculture, the Civil War, and the history of military installations, utilities, and infrastructure in the twentieth century.

Experience: 30+ years' experience in Section 106, NEPA, and Historic Preservation Planning for government, energy, and industrial sectors

Key Projects at ERM

Energy Client, Pipeline Project, 2015–2019
Conducted cultural resource investigations as part of the permitting of a 600-mile natural gas pipeline in three states. Prepared historical contexts, conducted research on properties, assessed effects of project on resources, prepared mitigation plans for NRHP-eligible properties. Federal Energy Regulatory Commission issued Programmatic Agreement approving implementation of mitigative measures to complete compliance with Section 106 of the National Historic Preservation Act.

Energy Client, Wind Energy Project, 2019–2020
Prepared a Cumulative Visual Effects Assessment for a proposed off-shore wind energy installation of 800-megawatts in the waters of Rhode Island and Massachusetts. The analysis incorporated 17 lease areas and 761 wind generating turbines from the proposed project and reasonable foreseeable future projects. The assessment focused on three historic properties, including a Traditional Cultural Property and a National Historic Landmark.

Energy Client, Wind Energy Project, 2017–2019
Developed context and assessed historic significance for resources in three county area of northeast Pennsylvania that might be affected by a series of proposed wind turbines sites. The context addressed thematic resource types of primary significance in the region including coal industry related sites, railroads, and agricultural properties.

Energy Client, NRHP Evaluation of LNG Terminal, 2019
Developed context and assessed historical significance of an LNG terminal in Alaska completed in 1969 that was the first to export LNG from the United States. The research addressed the process involved in liquefying natural gas and changes to the plant over time. The plant was recommended as eligible for the NRHP.

Energy Client, NRHP Evaluation of Abandoned Pipeline, 2018
Served as author of reports for four western states assessing the historical significance of a 700-mile former oil pipeline converted to natural gas that was slated for abandonment. The assessment was conducted in accordance with a Notice of Exemption issued by the Advisory Council on Historic Preservation regarding abandoned historic natural gas pipelines.

Manufacturing Client, NRHP Evaluation of Historic Orchard Property, 2018
Conducted historical research and produced historical context for historic apple orchard and other historic properties in Jefferson County, West Virginia. Assessed significance of properties and potential direct and visual effects of a fiber manufacturing facility.

Energy Client, Wind Energy Project, 2016–2017
Developed context and assessed historic significance for resources in four county area of northeast West Virginia that might be affected by a series of proposed wind turbines sites. The context addressed a number of resource types including historic coaling and lumber communities, railroads, and industrial sites. Assessed architectural resources for NRHP eligibility under Criteria A and B through local history sources, deed research, and genealogy. Prepared inventory forms for data entry.

Key Projects Prior to Joining ERM

Energy Client, NRHP Documentation, 2014
Researched the ownership history and development of the William Evans farmhouse and associated buildings using county records, historical maps, census returns, and other primary and secondary sources as part of a Memorandum of Agreement to mitigate the effects of a transmission line with a permanent archival record of the property

Government Agency, Nuclear Power Program History, 2013
Conducted historical research using documents from the agency's corporate libraries, records in the National Archives, contemporary newspaper articles, and secondary sources on the nuclear power industry to produce a fully-referenced, illustrated history of what was for many years the nation's largest nuclear power program. The agency commissioned this historical overview of its nuclear power program to provide a concise reference for the agency.

Government Agency, HABS Documentation, 2012
Examined project records and historic photographs, along with other primary and secondary sources to establish the history of the former project offices of the Falcon Dam Project on the Rio Grande, constructed in 1951.

Government Agency, NRHP Assessment, Levees and Water Control Features, 2010–2011
Researched the records of the U.S. Boundary and Waters Commission and the Bureau of Reclamation to assess the significance of two levees constructed on the Rio Grande to control flooding. The levees interfaced with irrigation systems constructed prior to the levees, which also had historic features.

Government Agency, Oral History Documentation of Federal Housing Project, 2009
Conducted historical research on two housing projects slated for demolition using records at the local historical societies and libraries. Current residents of the developments were interviewed about their experiences in public housing. The documentation was part of a recordation of the two facilities intended to produce a comprehensive history of the public housing prior to the sale of the properties by the city.

Energy Client, Pipeline Project, 2008
Produced statewide contexts for five states, as well as more specific histories for dozens of counties and parishes along a 507-mile natural gas transmission pipeline in the southeast U.S. Historical research was also conducted on identified architectural resources to aid the assessment of their NRHP significance. The project was conducted on a short time schedule.

Military Agency, Air Force Facility History, 2006
Served as Historian and Author for the production of a pictorial history of Air Force Plant 6, an aircraft assembly plant operated by Bell Aircraft Company during World War II and later by Lockheed Aeronautics Company and its successors. The book is a fully-illustrated, perfect-bound history of the plant intended for a general audience and was distributed to libraries, government agencies, and other interested organizations.

Government Agency, Cultural Resources Survey of Redevelopment Property, 2006
Researched agency records and photographs on site and at the National Archives Southeast Region Branch in Atlanta, as well as local facilities to document the history and historic significance of a portion of the agency's reservation. The site included numerous industrial properties related to weapons manufacture in World War I, New Deal agricultural programs, and hydroelectric power. The assessment of the facilities was later used to develop an adaptive reuse plan for the property.

Government Agency, Archaeological Data Recovery in Historic District, 2006
Served as a Historian for this investigation of two blocks of a commercial and residential street in a historically black neighborhood of Savannah, Georgia. Using Sanborn Fire Insurance maps, city directories, and a variety of historical sources, documented neighborhood development, racial and social composition, and landscape characteristics over a period of approximately 100 years. The information was applied to the archaeological evidence from the excavation of features related to domestic and business activities on the street during the early twentieth century. A popular pamphlet on the results of the investigation was also produced.

Government Agency, Historical Research for NRHP Historic District Nomination, 2005
Conducted background research on the history of town in West Georgia, the evolution of the built environment within the district, and the construction date of the buildings, as part of a survey of 60+ properties for this historic downtown historic district. The information was used for an NRHP nomination submitted to the Georgia SHPO, and the district was listed in 2007.

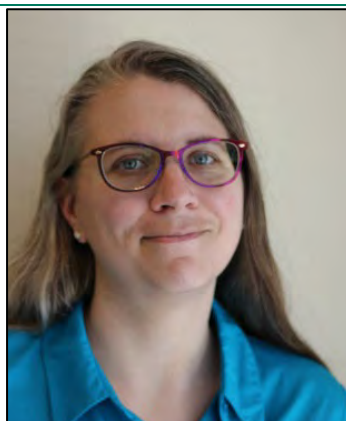
Energy Client, NRHP Assessment of Hydroelectric Power System, 2004
This project involved a review of historical documents related to the design and construction of 11 dams and powerhouses along two major rivers in North and South Carolina. Published histories, company documents, contemporary accounts were consulted, and similar large-scale power and flood-control projects in the Southeast and in the United States were studied to assess the significance of a series pf projects that spanned two states and included multiple facilities along an entire river system.

Military Agency, Context and NRHP Assessment of Korean War and Cold War Structures, 2003
Conducted background research to develop historic contexts to aid in the interpretation and assessment of BASOPS structures from the Korean War and Cold War periods at Fort Bliss and Briggs Army Airfield, Texas. The assessment of the facilities required the application of NRHP guidelines for properties of exceptional significance but less than 50 years old.

Emily Tucker-Laird

Senior Architectural Historian and Archaeologist

Ms. Tucker-Laird is Secretary of the Interior Qualified as an architectural historian and archaeologist. Emily is based in ERM's Duluth Georgia office, and attached to the cultural resources field services group. Emily has extensive experience working as a Principal Investigator. Her projects have included intra and interstate pipelines, electrical transmission lines, wind projects, solar projects, microwave towers, and treatment plans. In addition to fieldwork, Emily has experience supervising and coordinating for complex projects, and developing treatment plans for historic property concerns. Emily's has consulted with a wide range of state and federal agencies, as well as local stakeholders and interested parties.



Experience: 15 years of experience in the field of Cultural Resource Management

Key Projects

Energy Client, Wind Project, 2016
Architectural historian 2016 for a 72-turbine wind project in Grant and Tucker County West Virginia. Key tasks included field survey and reporting, and analysis of visual simulations. Project met the requirements of the West Virginia Public Service Commission, and Section 106.

Energy Client, Pipeline Project, 2015-present
600-mile-long natural gas pipeline extending from West Virginia to North Carolina. Architectural Historian and Principal Investigator for historic architecture survey and assessment of effects and Historic Architecture Task Manager responsible for overseeing treatment plans to mitigate project effects. Task Manager for FCC tasks. Responsibilities also include consultations with the FERC, SHPO, and consulting parties.

Energy Client, Transmission Line Project, 2017
Six transmission line alternatives in Fairfax County, Virginia. Cultural resource specialist who prepared sections of the routing study, SCC application, and pre-application analysis, and conducted the technical review for the cultural resource investigations conducted for a proposed line to be sited in northern Virginia.

Energy Client, Pipeline Project, 2016
Architectural Historian for a 96-mile natural gas pipeline in Calcasieu, Jefferson Davis, Acadia, and Evangeline parishes. Completed architectural survey to meet the requirements of the FERC and LASHPO.

Telecommunications Client – Nationwide 2014-2015
Architectural Historian and Archaeologist for a nationwide NEPA Program Management Team serving a major national telecommunications carrier. Provide QA/QC oversight on cultural resources submittals and client deliverables. Tasks include assuring that all compliance submittals conform to regulatory requirements as well as meeting client standards, and assuring that required documentation of compliance is included in all client deliverables.

Key Projects before Joining ERM

Energy Projects, 2012
Muscle Shoals Reservation, Alabama: Architectural Historian for the HABS Level II documentation of selected resources of the Tennessee Valley Authority Muscle Shoals Reservation. The architectural survey included a detailed survey of both the interior and exterior of 20 resources. Final products included a photographic record, historical context of each resource, and architectural descriptions.

City Planning Project, 2010
Georgetown, SC Historic District Survey: One of a team of Architectural Historians recording 900 resources within the National Register-listed historic district. Final products included a comprehensive historic district inventory, maps which identified building by period of construction and contributing status, South Carolina Department of Archives and History Intensive-level historic structure forms and photographs, and a report.

Macon Cemetery Preservation Corporation, 2007
Cemetery Preservation Plan in Georgia: Architectural Historian for a conditions assessment of the 13-acre Linwood Cemetery. Containing over 4,000 burials. Identified the extent of interments, overall conditions across the cemetery, and specific graves and markers requiring repair and stabilization. The product of the work was an assessment of the cemetery's condition and a preservation plan.

Energy Client, Lateral Pipeline Project, 2013-2015
75-mile crude oil pipeline in Illinois and Indiana: Principal Investigator for historic structures, Field Director and Crew Coordinator for the project. Managed several crews, and subcontractors, met with the land office to determine what was available for survey, and acted as the health and safety officer.

Description

A comprehensive survey of the pipe penetrations and backflow prevention measures for the Grand River Flood Protection System (GRFPS) was completed. The reaches, shown in Figures 1 through 10, are along the Grand River in Grand Rapids and Walker, Michigan and consist of the following:

East Side of Grand River

- Reach E1 – Knapp Street downstream to Leonard Street.
- Reach E2 – Leonard Street downstream to Interstate Route 196 (I-196).
- Reach E3 – Gillett Pedestrian Bridge downstream to U.S. Route 131 (US 131).
- Reach E4 – US 131 downstream to 50% distance to the Water Resource Recovery Facility (WRRF).
- Reach E5 – WRRF perimeter levee

West Side of Grand River

- Reach W1 – U.S. Route 131 ramp crossing of railroad track in the City of Walker downstream to Indian Mill Creek and then up Indian Mill Creek along the north bank for approximately 2,400 feet to the second railroad bridge.
- Reach W2 – Down Indian Mill Creek along the south bank from second railroad bridge crossing for approximately 2,400 feet to the confluence with the Grand River and then downstream to I-196.
- Reach W3 – I-196 downstream to Fulton Street.
- Reach W4 – Fulton Street downstream to the Butterworth Landfill.

This survey included the following:

- Review of floodwall and levee construction plans.
- Review of highway drainage construction plans provided by the Michigan Department of Transportation (MDOT).
- Visual inspection of the riverside face of the flood protection system to document the location of outfalls and backflow prevention devices installed on the floodwalls and ends of individual pipes and to determine if the outfalls were active or abandoned.
- Inspection of backflow prevention devices installed in upstream manholes (including flap gates, bolt-down manhole castings, slide gates, and bulkheads).
- Discussions with private property owners and inspections of storm water drainage pipes from these properties.

According to 44 CFR 65.10(b)(2), “All openings must be provided with closure devices that are structural parts of the system during operation and design according to sound engineering practice”. Under the provisions of FEMA’s *Analysis and Mapping Procedures for Non-Accredited Levee Systems*, dated July 2013, the City is seeking Freeboard Deficient Reach status for the GRFPS. For Freeboard Deficient Reach status, the following conditions must be met:

- The flood protection floodwalls and embankments (levees) must be above the Base Flood Elevation (BFE) defined as the 100-year return interval flood elevation.
- There must be closure structures/devices on any penetrations through and any openings in the floodwall and earth embankments (levees) to prevent backflow of water into the protected areas. The closures structures/devices must provide protection to a level above the BFE.

- An Operations and Maintenance Plan covering the effective reaches must meet the standards of 44CFR65.10(c).
- The structural design of floodwalls and levees within the effective reaches must meet the design standards for closures in 44 CFR 65.10(b)(2).

Inspection

The pipe penetrations, flap gates, bolt-down manhole lids, and sluice gates within each reach were located and visually inspected in the period 2014 - 2015. Figure 11 shows the outfall locations that received improvements to backflow prevention measures as a result of the inspections. All of the active pipe penetrations with outfalls below the BFE have flap gates, bolt-down manhole lids, or sluice gates as the primary means of backflow protection. The Wealthy Street, Market Avenue, Front-Scribner, Caledonia Street and Palmer Street Storm Water Pump Stations have flap gates on their outlet conduits to prevent backflow into the wet wells. Inactive pipe penetrations have all been plugged. The inactive pipe penetrations have not been included in the tables at the end of this report.

During the inspection, several flap gates were observed to be damaged and not in working order. In addition, several floodwall penetrations with outfalls below the BFE did not have flap gates. The City installed flap gates on the active pipe penetrations, repaired the damaged flap gates, and plugged the inactive pipe penetrations under "Grand River Floodwall Contract No. 1 (Backflow Prevention)" in 2016.

Pipe Penetrations

Reach E1

Within Reach E1, 20 active outfalls were identified along the Grand River of which 2 are for upland sewers with no inlets below the BFE and have bolt-down manhole castings below the BFE, 15 had flap gates, 1 had both a flap gate and inlets above the BFE with bolt-down manhole castings along the upland sewer, 1 was for a roof drain with inlets above the BFE, and 1 was controlled by a pressure relief valve. For the pipes designated as having inlets above the BFE in Reach E1, all meet the freeboard requirements of 44 CFR 65.10(b)(1)(i).

All of the active pipe penetrations below the BFE, except for the roof drain that discharges to outfall 62, have primary backflow devices (bolt-down manhole lids, sluice gates, or flap gates). The flap gates are mounted on the surface of the floodwalls, embankment headwalls, inside manholes, or on the ends of the pipes. Table 1 provides a summary of the GRFPS outfalls below the BFE in Reach E1, and the outfall locations are shown on Figure 2. Note the stationing used in Table 1 (and subsequent tables) is consistent with the river stationing used in the HEC-RAS water surface profile model of the Grand River approved by FEMA for Grand Rapids. The stationing represents feet from the mouth of the Grand River at Lake Michigan.

Reach E2

Within Reach E2, 10 active outfalls were identified along the Grand River. For the 10 active pipe penetrations, 2 had inlets above the BFE, 6 had flap gates, 1 was for an upland sewer with no inlets below the BFE and with bolt-down manhole lids below the BFE, and 1 had inlets above the BFE and a flap gate. For the pipes designated as having inlets above the BFE in Reach E2, all meet the freeboard requirements of 44 CFR 65.10(b)(1)(i).

All of the active pipe penetrations below the BFE have primary backflow devices (flap gates) or inlets above the BFE with bolt-down manhole castings along the upland sewers. Five of the flap gates are installed in manholes upstream from the river and 1 is mounted on the floodwall. Table 2 provides a summary of the GRFPS outfalls below the BFE in Reach E2, and the outfall locations are shown on Figure 3.

Reach E3

Within Reach E3, 16 active outfalls were identified along the Grand River. For the 16 active pipe penetrations, 6 had inlets above the BFE, 1 had both a flap gate and inlets above the BFE, and 9 had flap gates. Table 3 provides a summary of the GRFPS outfalls below the BFE in Reach E3, and the outfall locations are shown on Figure 4.

In Reach E3 outfalls 21B, 21C, 22, 22A, and 31A meets the requirements of 44 CFR 65.10(b)(1)(i) and outfalls 21A and 29A meet the requirements for Freeboard Deficient Reach status. For the pipes in Reach E3 that do not meet the freeboard requirements, additional closure measures may be needed to meet full accreditation requirements per 44 CFR 65.10(b)(1)(i) and 44 CFR 65.10(b)(2).

Reach E4

Within Reach E4, 12 active outfalls were identified along the Grand River. For the 12 active pipe penetrations, 5 had inlets above the BFE, 7 had flap gates. Table 4 provides a summary of the GRFPS outfalls below the BFE in Reach E4, and the outfall locations are shown on Figure 5.

In Reach E4 there are 5 pipes with inlets above the BFE with 4 (outfalls 13, 14, 18A, and 19) that meet the requirements of 44 CFR 65.10(b)(1)(i) and 1 (outfall 21-A) that meet the requirements for Freeboard Deficient Reach status. For the pipes in Reach E4 that do not meet the freeboard requirements, additional closure measures may be needed to meet full accreditation requirements per 44 CFR 65.10(b)(1)(i) and 44 CFR 65.10(b)(2).

Reach E5

Reach E5 consists of the ring levee that encircles the WRRF. Within Reach E5, 6 active outfalls were identified through the levee sections along the Grand River. Two of the active pipe penetrations had inlets above the BFE with sluice gate closures within the WRRF. The remaining 4 levee penetrations are for storm and sanitary sewers that extend from the CSX property on the south side of the WRRF. These 4 pipes are controlled using manually operated gate valves operated from the crest of the levee. Table 5 provides a summary of the GRFPS outfalls below the BFE in Reach E5, and the outfall locations are shown on Figure 6. Both of the outfalls from the WRRF meet the requirements of 44 CFR 65.10(b)(1)(i).

Reach W1

Within Reach W1, 16 active pipe penetrations were identified through the levee along the Grand River, including 12 in the City of Walker north of the Grand Rapids boundary, and 6 along the left (north) bank of Indian Mill Creek. Along the Grand River, 5 of the active outfalls had inlets above the BFE, 4 of the outfalls were in the floodplain and were protected by outfalls further along the drainage path, and 7 had flap gates. The Indian Mill Creek outfalls included 3 with flap gates, 2 with inlets above the BFE, and 1 had no backflow protection. During the base flood in the Grand River, water would backflow up this outfall without backflow protection (outfall 141) resulting in flooding of a truck well with no flooding of adjacent areas.Table 6 provides a summary of the GRFPS outfalls below the BFE in Reach W1, and the outfall locations are shown on Figure 7.

For the outfalls with inlet invert elevations above the BFE, 3 of the outfalls along the Grand River (outfalls 133B, 134, and134A) and 1 along Indian Mill Creek (outfall 136-C) meet the requirements of 44 CFR 65.10(b)(1)(i). Outfalls 135 and135B2 along the Grand River and outfall 139 along Indian Mill Creek have inlet invert elevations above the BFE and meet the requirements for Freeboard Deficient Reach status. For the pipes in Reach W1 that do not meet the freeboard requirements, additional closure measures may be needed to meet full accreditation requirements per 44 CFR 65.10(b)(1)(i) and 44 CFR 65.10(b)(2).

Reach W2

Within Reach W2, 27 active pipe penetrations were identified through the levee/floodwall along the Grand River and 1 along the south bank of Indian Mill Creek.

For the 27 active pipe penetrations along the Grand River, 6 had inlets above the BFE, 18 had flap gates, 2 were manually closed using inflatable plugs (see Appendix 2) per the GRFPS Emergency Action Plan, and 1 had its inlet in the floodplain where backwater would be contained to the immediate area. The 1 active outfall along the right (south) bank of Indian Mill Creek was protected by a flap gate. Table 7 provides a summary of the GRFPS outfalls below the BFE in Reach W2, and the outfall locations are shown on Figure 8.

In Reach W2, the 5 outfalls with inlets above the BFE include 4 outfalls (outalls 109A, 109B, 110A, and 111) that meet the requirements of 44 CFR 65.10(b)(1)(i) and 1 outfall (outfall 123) that meets the requirements for Freeboard Deficient Reach status. For the pipe in Reach W2 that does not meet the freeboard requirements, additional closure measures may be needed to meet full accreditation requirements per 44 CFR 65.10(b)(1)(i) and 44 CFR 65.10(b)(2).

Reach W3

Within Reach W3, 14 active outfalls along the Grand River were identified including 8 outfalls with inlets above the BFE, 2 outfalls protected by flap gates, and 4 outfalls without backflow protection because their inlets were in the floodplain. Table 8 provides a summary of the GRFPS outfalls below the BFE in Reach W3, and the outfall locations are shown on Figure 9.

For the outfalls with inlets above the BFE in Reach W3, 5 outfalls are in natural ground with the top of bank elevation above the BFE (outfalls 105A, 105B, 105C, 107, and 107C) and 2 outfalls (outfalls 99A and 100) are for roof drains. These outfalls meet the requirements of 44 CFR 65.10(b)(1)(i). The remaining outfall with an inlet above the BFE (outfall 97) meets the requirements for Freeboard Deficient Reach status. For the pipe in Reach W3 that does not meet the freeboard requirements, additional closure measures may be needed to meet full accreditation requirements per 44 CFR 65.10(b)(1)(i) and 44 CFR 65.10(b)(2).

Reach W4

Within Reach W4, 20 active outfalls along the Grand River were identified including 4 with inlets above the BFE, 1 with a duckbill valve, 11 with flap gates, 2 protected by flap gates downstream of their outfalls, 1 with a manual sluice gate, and 1 that was manually plugged. The manually plugged outfall (outfall 83D) is included as one of the "action items" in Table 4 of the GRFPS Emergency Action Plan. Table 9 provides a summary of the GRFPS outfalls below the BFE in Reach W4, and the outfall locations are shown on Figure 10.

For the outfalls with inlets above the BFE in Reach W4, 3 outfalls (outfalls 83C, 86-A and 87) are for roof drains and meet the requirements of 44 CFR 65.10(b)(1)(i). The remaining outfall with an inlet above the BFE (outfall 81-A) meets the requirements for Freeboard Deficient Reach status. For the pipe in Reach W3 that does not meet the freeboard requirements, additional closure measures may be needed to meet full accreditation requirements per 44 CFR 65.10(b)(1)(i) and 44 CFR 65.10(b)(2).

Bridge Approach Closures

There are 14 bridges over the Grand River within Reaches E1 to E4 and no bridges in Reach E5. The same 14 bridges occur in Reaches W1 to W4 plus 1 additional bridge in Reach W3 and 3 additional bridges over Indian Mill Creek in Reaches W1 and W2. The minimum elevation for each bridge roadway approach on the east and west banks of the Grand River and the north and south banks of Indian Mill Creek were evaluated to determine if a closure structure is needed to meet the closure requirements of 44 CFR 65.10(b)(2) and the freeboard requirements of 44 CFR 65.10(b)(1)(i). Tables 10 and 11 summarize the minimum bridge roadway approach elevations with respect to the BFE.

Seven of the 14 east bridge roadway approaches and 7 of the 15 west bridge roadway approaches were less than 3 feet above the BFE. Six of these bridges (6th Street, Fulton Street, Blue Pedestrian, Pearl Street, Gillett Pedestrian, and Wealthy Street) had east and west bridge approaches that were above the BFE. The west approach of the CSX Railroad Bridge upstream of Wealthy Street was less than the BFE. Table 4 in the GRFPS Emergency Action Plan stipulates that a fabricated temporary closure be installed at the west approach to the CSX Railroad Bridge upstream of Wealthy Street to close the opening in the flood protection system. Drawings of the closure are included in Appendix 3 of this report.

The bridges with roadway approaches above the BFE but less than 3 feet above the BFE meet the requirements for a freeboard deficient reach, but not full FEMA accreditation. For full accreditation, closure structures will be required for the east and west side of these bridges to meet the closure requirements of 44 CFR 65.10(b)(2) and the freeboard requirements of 44 CFR 65.10(b)(1)(i). All of the remaining bridges over the Grand River and the 2 bridges over Indian Mill Creek have roadway approach elevations greater that 3 feet, which meet the requirements of 44 CFR 65.10(b)(2) and the freeboard requirements of 44 CFR 65.10(b)(1)(i) for full accreditation.

Sidewalk Closures

One temporary closure is required for a sidewalk penetrating through the flood control berm at Fishladder Park on the west side of the river at station 2159+21. The aluminum closure was special fabricated and is 9’ 8” wide by 5’ 3” tall with a mid-span support and ten 4’ 10” aluminum flood logs. Construction plans for the closure structure are included in Appendix 1. The closure is stored in the Front and Scribner Stormwater Pump Station maintenance building located 180 feet to the south. The closure meets the requirements for freeboard deficient certification.

Outfalls with Inlets Above BFE

Several outfalls along the GRFPP do not have flap gates, sluice gates or duckbill valves to prevent backflow during floods. These outfalls are located on storm water drainage pipes that have inlets above the BFE and bolt-down manhole lids on any manholes between the river and the inlets. Materials Testing Consultants, Inc. (MTC) prepared a revised geotechnical analysis to evaluate floodwall stability and possible soil heave behind the floodwall that could result from seepage at joints or points of damage in their report “*Revised Geotechnical Report, Grand River Floodwall and Embankment Stability, Grand Rapids, Michigan*” dated March 2018, which is included in the stability and settlement analysis section of the GRFPP levee certification documents. The results of this analysis indicate that this type outfall will not cause any floodwall instability or result in soil heave that would cause interior flooding.

* Stations and BFE's are referenced to the confluence of Indian Mill Creek with the Grand River.

Conclusions

Primary closures for the GRFPS consist of backflow prevention devices on the pipe penetrations through the levee and floodwall sections. The primary backflow prevention devices consist of flap gates on the pipe outfalls or in upstream manholes, duckbill valves, pressure release valves, sluice gates, and bolt-down manhole lids that result in water backing up in some pipes such that the inlet invert elevations are above the BFE. The outlet conduits and pump discharge pipes for the five storm water pump stations in the GRFPS have flap gates installed.

The closures on the pipe penetrations through the levee, floodwall, and natural ground sections of the GRFPS provide protection from the 100-year flood, which is consistent with the requirements for Freeboard Deficient Reach status.

However, some of the pipe penetrations with inlet invert elevations above the BFE do not provide sufficient freeboard to meet the requirements of 44 CFR 65.10(b)(1)(i). The inlets for these pipes may need to be raised, additional bolt-down manhole lids installed, or new flap gates installed to meet the freeboard requirements for full accreditation of the reaches.

There are 14 bridges across the Grand River in Reaches E1 to E5 and 17 bridges in Reaches W1 to W4 including two bridges over Indian Mill Creek in the backwater from the Grand River.

The lowest roadway elevations at the east and west ends of each bridge over the Grand River, except for the west end of the CSX Railroad Bridge upstream of Wealthy Street, are above the BFE consistent with the requirements for Freeboard Deficient Reach status. The GRFPS Emergency Action Plan has provisions to install a fabricated temporary closure on the westside of the CSX Railroad Bridge upstream of Wealthy Street to provide protection to above the BFE. See Appendix 3 for closure drawings.

If at a future date the City decides to pursue full levee accreditation with respect to the closure and freeboard requirements of 44 CFR 65.10(b)(2) and (1)(i) for bridges, the following should be noted:

- The Wealthy Street Bridge, Fulton Street Bridge, Blue Pedestrian Bridge, Pearl Street Bridge, and Gillett Pedestrian Bridge all have minimum approach roadway elevations less than 4 feet above the BFE. Therefore, these bridges may need to have closure structures installed on the east and west ends of each bridge to meet the freeboard requirements for full accreditation.
- The CSX Railroad Bridge upstream of Wealthy Street has a west approach elevation less than the BFE and will need permanent closure structures on both ends to meet the freeboard requirements for full accreditation.

TITLE: Improvements to Grand River

DATE: 10.13.16

AS-BUILT
6/2017

GENERAL NOTES IBC:

1. The structural design of these removable flood panels has been designed for hydrostatic flood loads with water pressures corresponding to maximum water height as depicted in the enclosed drawings plus hydrodynamic pressure. Free board of 1 foot in ht. is added to the system height of each opening in accordance with the documents listed below in notes 2,3 and 5.
2. It shall be determined, on a job by job basis, the required Panel height and flow speed for the design of Removable Flood Panels, based on FEMA's criteria (See Note #3) as well as per ASCE 24–05 Standard. Installation and construction of these Flood Panels for use within flood hazard areas shall be in accordance with the American Society of Civil Engineers Flood Resistant Design and Construction Standard SEI/ASCE 24–05.
3. Design criteria has been based on the 2012 Edition of the International Building Code, the corresponding provisions of ASCE 24–05, FEMA flood proofing non–residential structures manual FEMA 102, FEMA P–936 dated July, 2013 and FEMA Technical Bulletin 3–93. Design flood loads have been determined in accordance with ASCE 7–10. Design wind loads have been determined in accordance with ASCE 7–10 for 130 mph Basic Wind Speed for category 2 building.
4. Flood Panels shall not be installed within areas where ice flows or ice jams occur.
5. In order to certify flood elevation, Flood Panel design have tested by an independent testing lab for water infiltration in accordance with FEMA 102 manual for flood proofing of non–residential structures, specifications Section 8, Page 70.
6. Flood Panel installer to use gaskets and approved sealants following all the recommendations and specifications of the manufacturers respectively.
7. Owner, General contractor or installer to verify all dimensions, wall and floor conditions at site before proceeding with the work, and shall notify this engineer if any discrepancy is found that would alter the structural design of these Flood Panels.
8. Existing slabs and walls adjacent to opening where Flood Panel is to be installed shall be given a surface treatment by means of water proof sealer before flood Panel is installed. Surface must be smooth, square, plumb and level.
9. Existing slabs and walls adjacent to openings where Flood Panels are to be installed shall be structurally designed by engineer of record, to sustain the same hydrostatic, hydrodynamic and impact pressures that correspond to maximum water elevation above finished floor at top of Panel , based on criteria mentioned on Note #3.
10. Drop–in anchors embedded into concrete for removable support installation shall be covered with a cap or similar device to protect their inside hold from dust, so that machine screws can easily be installed at time of flood warning. Concrete anchors by others.
11. Separation of Panel to window/door shall be measured from back of Panel to window/door including any knob, handle, or protruding device, and shall be 2" minimum.
12. All aluminum extrusions to be 6063–T6 alloy, and 6005–T5 alloy.
13. All sheet metal screws shall be as manufactured by ITW/Buildex "TEK Screws", and to be made of non–corrosive material.
14. All bolts to be galvanized steel ASTM A–307 designation or 304 Series Stainless Steel.
15. All gaskets installed shall be neoprene per drawings.
16. All welding to conform to the American Welding Society AWS D1.2. 1998 Regulations. Use certified welders. Use ER–5356 Electrodes.
17. The engineer, Architecture Metals Ltd. or Flood Panel LLC. is not responsible for construction safety at site which is the owner, general contractor or installer's responsibility. Flood Panel Manufacturer to be responsible for providing the tenant with shop drawings and proper instructions for the installation of these Flood Panels.
18. Surfaces against which the sealing gasket presses must be built "paper–smooth" to prevent excessive water extrusion, beyond that allowed by requirements. All surfaces must be plumb, square and level.
19. To receive a warranty for the flood barriers provided by Flood Panel LLC as depicted in this set of drawings, the following information must be provided by the building owner to Flood Panel LLC:

To receive credit for flood proofing, a completed Flood proofing Certificate for Non–Residential Structures is required for non–residential and business buildings in the Regular Program communities, located in zones A1–A30, AE, AR, AR Dual, AO, AH, and A with BFE.

In order to ensure compliance and provide reasonable assurance that due diligence had been applied in designing and constructing flood proofing measures, the following information must be provided with the completed Flood proofing Certificate:

1. Photographs of shields, gates, barriers, or components designed to provide flood proofing protection to the structure installed and deployed on the building.
2. Written certification that the barrier system was inspected during and after initial installation and is installed per the drawings, engineering and instructions provided by the manufacturer.
3. Written certification that the envelope of the structure is watertight with walls substantially impermeable to the passage of water required under 44 Code of Federal Regulations (44 CFR 60.3 (c)(3))
4. A comprehensive Maintenance Plan for the entire structure to include but not limited to:
   - Exterior envelope of the structure
   - All penetrations to the exterior of the structure
   - All shields, gates, barriers, or components designed to provide flood proofing protection to the structure
   - All seals or gaskets for shields, gates, barriers, or components
   - Location of all shields, gates, barriers, and components as well as all associated hardware, and any
   - Materials or specialized tools necessary to seal the structure.

U.S. DEPARTMENT OF HOMELAND SECURITY
FEDERAL EMERGENCY MANAGEMENT AGENCY
National Flood Insurance Program
NFIP Flood proofing

19. Responsibility for filing the building "Flood Proofing Certificate" is the responsibility of the owner's architect and/or engineer and not of Architecture Metals Ltd. or Flood Panel LLC.

Inflatable Plug Manufacturer's Literature

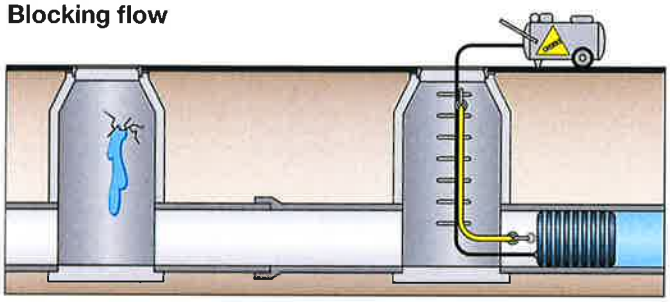
Test Ball® Plugs – Underground

Cherne's Original Single Size and Multi-Size Test Ball Plugs are our most economical pneumatic plugs for blocking flow to do maintenance in sanitary and storm sewer systems. These plugs may also be used as a back plug for sewer air tests.

All of the single-size and multi-size Test Ball plugs have eyebolts for attaching a rope or clevis for lifting and lowering the plug. And each plug also has a removable Schrader valve for easy replacement or substitution with a quick disconnect fitting.

Made from natural rubber, these plugs are tough, tear-resistant and will work on any type of pipe, including out-of-round pipe.

Blocking flow



Single Size Original Test Balls

Part Number	Nominal Size	Usage Range	Maximum Back Pressure		Inflation Pressure	Product Weight	Deflated Length	Deflated Diameter	Inflation Thread	Chain / Eye bolts
041386	8" (200 mm)	7"-8.25" (178-210 mm)	17 psi (1,2 bar)	40 ft. (12 M)	25 psi (1,7 bar)	3.4 lbs (1.6 kg)	10.25" (257 mm)	6.75" (172 mm)	1/4" (1)	3/8" (1)
041394	10" (250 mm)	9"-10.25" (229-260 mm)	17 psi (1,2 bar)	40 ft. (12 M)	25 psi (1,7 bar)	5.6 lbs (2.5 kg)	11.75" (298 mm)	8.75" (221 mm)	1/4" (1)	3/8" (1)
041408	12" (300 mm)	10.5"-12.25" (267-311 mm)	17 psi (1,2 bar)	40 ft. (12 M)	25 psi (1,7 bar)	10.9 lbs (5 kg)	13.75" (351 mm)	10.25" (262 mm)	1/4" (1)	3/8" (1)
041416	15-16" (375-400 mm)	14" - 16.25" (356-413 mm)	13 psi (0,9 bar)	30 ft. (9,1 M)	25 psi (1,7 bar)	29.5 lbs (13.4 kg)	19.75" (502 mm)	13.75" (346 mm)	1/4" (1)	3/8" (2)

Multi-Size Original Test Balls

Part Number	Nominal Size	Usage Range	Maximum Back Pressure		Inflation Pressure	Product Weight	Deflated Length	Deflated Diameter	Inflation Thread	Chain / Eye bolts
275048	4" - 6" (100-150 mm)	3.75"-6.25" (92-159 mm)	17 psi (1,2 bar)	40 ft. (12 M)	30 psi (2,1 bar)	2 lbs (0.91 kg)	9.8" (250 mm)	3.5" (85 mm)	1/8" (1)	1/4" (1)
275058	6" - 8" (150-200 mm)	5.25"-8.25" (135-210 mm)	17 psi (1,2 bar)	40 ft. (12 M)	30 psi (2,1 bar)	3.5 lbs (1.6 kg)	14" (356 mm)	5" (127 mm)	1/4" (1)	3/8" (1)
275088	8" - 12" (200-300 mm)	7"-12.25" (178-311 mm)	11 psi (0,75 bar)	25 ft. (8 M)	20 psi (1,4 bar)	6.63 lbs (3 kg)	16" (406 mm)	6.75" (171 mm)	1/4" (1)	3/8" (1)
275128	12" - 18" (300-450 mm)	10.75"-18.25" (273-464 mm)	11 psi (0,75 bar)	25 ft. (8 M)	25 psi (1,7 bar)	22.4 lbs (10.2 kg)	24" (610 mm)	10.5" (267 mm)	1/4" (1)	3/8" (1)

Always block plugs when conducting air tests.

Engineers | Architects | Scientists | Constructors

44 CFR 65.10 (b) (3) Tab

(3) *Embankment protection.* Engineering analyses must be submitted that demonstrate that no appreciable erosion of the levee embankment can be expected during the base flood, as a result of either currents or waves, and that anticipated erosion will not result in failure of the levee embankment or foundation directly or indirectly through reduction of the seepage path and subsequent instability. The factors to be addressed in such analyses include, but are not limited to: Expected flow velocities (especially in constricted areas); expected wind and wave action; ice loading; impact of debris; slope protection techniques; duration of flooding at various stages and velocities; embankment and foundation materials; levee alignment, bends, and transitions; and levee side slopes.

1.0 Introduction

The Grand River Flood Protection System (GRFPS), shown in Figure 1, is along the Grand River in Grand Rapids, Michigan and consists of the following:

- Approximately 22,760 feet of earthen embankment levee including 12,670 feet along the left (east) bank and 10,090 feet along the right (west) bank;
- Approximately 7,560 feet of ring dike around the Grand Rapids Wastewater Treatment Plant;
- Approximately 16,210 feet of counterfort, gravity, and cantilevered reinforced concrete floodwall including 6,620 feet along the left (east) bank and 9,950 feet along the right (west) bank;
- 136 pipe penetrations through the levee, floodwall, and natural bank sections with flap gate closures, rubber duck-billed valves, sluice gates, or bolt-down manhole covers for backflow prevention; and
- 6 storm water pumping stations.

The GRFPS was designed and constructed by the City of Grand Rapids (City) to meet the level of the 100-year return interval flood. The most recent construction of the flood prevention works was completed in 2017. The City flood maps are being converted to digital flood insurance rate maps (DFIRM) as a result of Federal Emergency Management Agency's (FEMA) Flood Map Modernization Program (FMMP). The GRFPS is subject to the levee certification requirements of 44 CFR 65.10; however, the City is currently seeking freeboard deficient reach status for all reaches, except Reach E5, as provided by the Federal Emergency Management Agency's (FEMA) Analysis and Mapping Procedures for Non-Accredited Levee Systems, dated July 2013. The City is seeking full accreditation for Reach E5.

The provisions of 44 CFR 65.10 include 7 requirements necessary to certify a flood protection project including an engineering analysis to evaluate the flood protection works for erosion during the 100-year flood. In terms of the GRFPS, the structures that would be subject to erosion during the 100-year flood would be the natural stream banks and earth embankment levees, all of which face the Grand River. Approximately 7,220 feet of stream bank and levee embankments are protected by riprap embankment protection from the levee embankment or stream bank toe to various elevations depending on location. This report summarizes the analysis performed by Fishbeck, to evaluate the adequacy of the GRFPS levee embankment and stream bank protection to prevent erosion caused by the Grand River in Grand Rapids, Michigan during the 100-year flood.

2.0 Background

The GRFPS was designed and constructed by the City in the period 1907 to 2017. The earth embankment levees were largely constructed atop existing ground along the river's edge and have varying slopes and crest widths. The concrete retaining walls are of the counterfort, gravity, and cantilever types.

As part of the Levee Analysis and Mapping Procedures (LAMP) agreed to by the City and FEMA, FEMA divided the GRFPS into reaches for evaluation. The reaches shown in Figure 1 are along the Grand River in Grand Rapids, Michigan and consist of the following:

East Side of Grand River

- Reach E1 – Knapp Street downstream to Leonard Street.
- Reach E2 – Leonard Street downstream to Interstate Route 196 (I-196)
- Reach E3 – Gillett Pedestrian Bridge downstream to U.S. Route 131 (US 131)
- Reach E4 – US 131 downstream to 50% distance to the Water Resource Recovery Facility (WRRF)
- Reach E5 – WRRF Boundary

West Side of Grand River

- Reach W1 – North city boundary downstream to Indian Mill Creek and along the north bank of Indian Mill Creek for approximately 2,400 feet
- Reach W2 – Lower 2,400 feet of the south bank of Indian Mill Creek and then downstream along the Grand River to I-196
- Reach W3 – I-196 downstream to Fulton Street
- Reach W4 – Fulton Street downstream to the Butterworth Landfill

Viewed in the downstream direction, the left (east) bank flood protection measures begin in Reach E1 with a former earthen railroad embankment, including a hiking/biking trail on its crest, that starts at Knapp Street and extends 5,150 feet along the river in the downstream stream direction to natural topography above the 100-year flood upstream of Leonard Street. The natural topography section extends past Leonard Street for a distance of 1,660 feet in the downstream direction into Reach E2. At this point, a levee embankment section begins and extends downstream 3,360 feet to a 380-foot long section of concrete floodwall that ends just south of the eastbound Interstate 196 (I-196) Bridge (downstream limit of Reach E2). A 1,880-foot long section of natural topography above the 100-year flood elevation begins just south of the eastbound I-196 bridge and continues in the downstream direction to the Gillett Pedestrian Bridge. This section of the east bank of the Grand River is not included in the FEMA designated reaches. Reach E3 begins at the Gillett Pedestrian Bridge with an approximately 100-foot long section of concrete plaza structure and then a 1,430-foot long section of concrete floodwall that extends in the downstream direction past the Fulton Street Bridge. The concrete floodwall ends at a 600-foot long section of natural topography above the 100-year flood elevation that extends to U.S. Route 131 (downstream end of Reach E3).

Reach E4 begins on the downstream side of U.S. Route 131 with an earthen levee embankment section that extends about 750 feet downstream along the river to a concrete floodwall section. The flood wall section extends about 1,070 feet to a 380-foot long section of earth embankment levee that ends at the Wealthy Street Bridge. From the Wealthy Street Bridge, a 3,540-foot long section of concrete floodwall extends in the downstream direction to the downstream end of Reach E4 at a section of natural ground above the 100-year flood elevation. Reach E5 consists of an earthen ring dike around the City Water Resources Recovery Facility (WRRF).

Flood protection works on the right (west) bank begin in Reach W1 with natural stream bank that extends from the City of Walker 3,500 feet in the downstream direction to the mouth of Indian Mill Creek. The natural stream

bank is lined with the earth embankment for U.S. Route 131. The natural stream bank in Reach W1 also wraps from the west bank along the Grand River to the north bank of Indian Mill Creek for a distance of about 2,400 feet to account for backwater from the Grand River. The natural stream bank along Indian Mill Creek is above the 100-year flood elevation for the Grand River. Reach W2 begins approximately 2,400 feet upstream of the Grand River along Indian Mill Creek with natural stream bank above the 100-year flood elevation for the Grand River. The natural stream bank extends to the railroad bridge at the confluence with the Grand River. From the railroad bridge there is an 890-foot long section of earthen levee embankment along the Grand River that ends at a concrete floodwall section south of the end of Richmond Street. The concrete floodwall section extends in the downstream direction for about 6,150 feet to the concrete fish ladder structure adjacent to the 4th Street Dam. Downstream of the fish ladder, there is a 2,070-foot long section of natural stream bank. This section extends past the I-196 Bridges (downstream end of Reach W2) into Reach W3 ending at the downstream side of the Michigan Street Bridge. From the downstream side of the Michigan Street Bridge, approximately 2,830 feet of earthen embankment levee with various configurations was constructed downstream to the Fulton Street Bridge (downstream end of Reach W3. Reach W4 begins at the downstream side of the Fulton Street Bridge with a concrete floodwall that follows the river bank in the downstream direction for 3,320 feet to the downstream side of the Wealthy Street Bridge. At this point, an approximately 2,870-foot long earth embankment levee section begins and extends to a point downstream of the Wealthy Street Storm Water Pump Station. The final section of the GRFPS in Reach W4 consists of an approximately 120-foot long embankment across the West End Ditch that spans between natural topography above the 100-year flood on both sides of the ditch.

The levee and floodwall sections have various configurations because they were constructed at different times for the City. Figure 2 illustrates typical levee embankment, stream bank, and floodwall cross-sections for the GRFPS. Plate 1 provides the location of each of the types of levee embankment, stream bank, and floodwall sections shown in Figure 2.

Riprap stone was placed on critical areas of the levee and natural stream banks to protect against erosion due to stream water velocity and impact by debris and floating ice (see photographs, Attachment 1). The provision of 44 CFR 65.10 do not identify the method to be used to analyze the adequacy of the riprap embankment protection; therefore, the riprap design guidance provided by the USACE Engineer Manuals EM 1110-2-1913, *Design and Construction of Levees,* and EM 1110-2-1601, *Hydraulic Design of Flood Control Channels*, and the specifications provided in the Michigan Department of Transportation (MDOT) *Standard Specifications for Construction* and the Michigan Department of Environmental Quality (MDEQ) *Guidebook of Best Management Practices for Michigan Watersheds* were used.

3.0 Levee Embankment

The earth embankment levee sections of the GRFPS have several different configurations including the following:

- Low earth berms consisting of compacted clay soils constructed atop natural stream banks. Some of these earth berms are located at the top of the stream bank slope while others are set back from the top of the stream bank slopes. In some cases, the earth berms are located behind a concrete retaining wall at the edge of the water.
- Railroad embankments constructed along the river's edge. The tracks atop these embankments have been removed and portions of the crest have been converted into hiking/biking trails.
- Roadway embankments for I-196 and U.S. Route 131. These embankments are set back from the river's edge.

The portion of the GRFPS that is exposed to the direct currents of the Grand River during flood events depends on the magnitude of the flood. For the 100-year flood, the entire length of the GRFPS is exposed to the direct currents of the stream. For the portion of the project that consists of levee embankment, riprap protection was placed on the stream-facing levee embankment slope at the following locations. Note that the stationing refers to the centerline of the mouth of Plaster Creek at the Grand River, which was assumed to be Station 72+00. The HEC-RAS model cross-section numbers refer to the hydraulic model of the Grand River discussed in the next section of this report.

- Left (East) Bank Station 129+47 to Station 133+77 (HEC-RAS cross-sections 209175.5 to 209683.8) – Embankment toe and slope protection.
- Left (East) Bank Station 146+03 to Station 149+93 (HEC-RAS cross-sections 210918.9 to 211242.4) – Embankment toe and slope protection.
- Left (East) Bank Station 160+85 to Station 169+75 (HEC-RAS cross-sections 212334.2 to 213128.6) – Stream bank toe and slope and floodwall protection.
- Left (East) Bank Station 198+48 to Station 201+88 (HEC-RAS cross-sections 216028.2 to 216378.8) – Stream bank and embankment toe and slope protection.
- Right (West) Bank Station 157+91 to Station 196+81 (HEC-RAS cross-sections 211918.1 to 215862.7) – Embankment toe and slope protection.
- Right (West) Bank Station 258+49 to Station 267+29 (HEC-RAS cross-sections 222516.4 to 222724.2) – Embankment toe and slope protection.

3.1 Grand River Flood Flow Velocities

The riprap protection on the levee embankments and stream banks exposed to the flow of the Grand River must be capable of withstanding the flow velocity during flood events up to and including the 100-year flood as well as forces resulting from floating ice and debris impact. The flow velocities along the levee face during the 100-year flood were determined using the current Grand River hydraulic model developed for the Federal Emergency Management Agency (FEMA) for the City of Grand Rapids Flood Insurance Study (FIS) using the HEC-RAS River Analysis System computer program. The HEC-RAS model was obtained directly from FEMA and run for the 100-year flood discharge (50,000 cfs) using a program option that determined the flow velocity distribution in the main channel and overbank areas of the river. The river reach in the HEC-RAS model that includes the flood-protection works for the City extends from river cross-section 198117.8 downstream to cross-section 244283.5 upstream (note that the river cross-sections on the Grand River are measured in feet in the upstream direction from the mouth at Lake Michigan). The HEC-RAS model results are included in Attachment 2 to this report and show that the maximum flow velocity along the left (east) bank of the Grand River for the 100-year flood was 7.96 feet per second at cross-section 216034.2 just upstream of the dam at the 6th Street Bridge Park. The maximum flow velocity along the right (west) bank was 7.95 feet per second at cross-section 208814.4 located immediately downstream of the Wealthy Street Bridge. Each section of the stream banks on both sides of

the river were evaluated for stream velocity and compared to the type of stream bank protection currently in place including concrete flood walls; concrete retaining walls with natural stream bank slopes above the wall and with and without earth berms; full-height natural stream banks; embankment slopes protected by riprap; and vegetated embankment slopes not protected by riprap. The distinction is made in this report between natural stream banks where no man-made flood protection measures have been constructed and erosion damage would not endanger the flood protection system and embankment sections where earth berms have been constructed on the natural stream bank and erosion damage could result in flooding behind the embankment.

Several government agencies have published guidelines for vegetative stream bank stabilization, including:

- *Illinois Urban Manual* published by the Association of Illinois Soil and Water Conservation Districts
- *Virginia Erosion & Sediment Control Handbook,* Standard & Specification 3.22, published by the Virginia Department of Conservation and Recreation
- *Approaches to the Design of Biotechnical Streambank Stabilization* published by the Joint Transportation Research Program, Purdue University

These guidelines indicate that vegetative stream bank protection is generally effective up to a stream velocity of about 5 feet per second. However, Table 3.22-A in the *Virginia Erosion & Sediment Control Handbook* also notes that where the frequency of bankfull flow is less than 1 time per year, vegetated streambank stabilization can have a maximum allowable velocity of 6 feet per second. Table 2 in *Approaches to the Design of Biotechnical Streambank Stabilization* indicates that moderate to dense vegetation (turf) can have permissible velocities from 4 to 8 feet per second. For Grand Rapids, the earth berms that are set back from the top of natural stream bank slopes are vegetated and not exposed to stream velocities greater than 5 feet per second, except for an area of streambank near the Water Resource Recovery Facility (WRRF) (streambank Type 10) between stream cross-section nos. 201740.0 and 203398.8 on the left (east) bank and just downstream of the first railroad bridge between cross-section nos. 205904.0 and 206315.8 on the right (west) bank (see Table 1). In these areas, the streambanks are heavily vegetated and almost impenetrable for inspection. Based on a site inspection on the left bank just upstream of the WRRF and site observations of the right bank, the vegetation consisted of the following tree, brush, and vine species with thickly intertwined roots:

- Boxelder (*Acer negundo*)
- Silver maple (*Acer saccharinum*)
- Eurasian honeysuckle (*Lonicera* spp.)
- Northern catalpa (*Catalpa speciose*)
- Common buckthorn (*Rhamnus cathartica*)
- Virginia creeper (*Parthenocissus quinquefolia*)

As further confirmation of the stability of the Type 10 streambanks, including those where the stream velocity along the bank exceeds 5 feet per second for the 100-year flood, FTC&H reviewed U.S. Geological Survey (USGS) topographic maps for changes to the location of the stream banks. No apparent changes were detected on maps that were issued by the USGS in 1914, 1958, 1962, 1967, 1969, 1972, 1980, 1981, 1984, 1996, 2011, and 2014. Lastly, for the reach to Type 10 streambanks along the left (east) bank of the river, FTC&H researched historic records for reports of streambank collapse and damage to Market Street between the WRRF and the first railroad bridge, but did not find any reports indicating problems with stream bank stability in this area.

The HEC-RAS model of the Grand River was run with an option allowing the stream channel and overbank areas to be divided into vertical sections for evaluation of stream velocity. For this study, the stream channel and left and right overbank areas were divided into 10 sections each. The results of the HEC-RAS analysis are provided in

Appendix 2. A summary of the flow velocities at the left (east) and right (west) stream banks is provided in Table 1.

* The cross-section number refers to the feet upstream of the confluence of the Grand River with Lake Michigan

** Velocity computations were not conducted by HEC-RAS for bridges using "multiple openings" option.

In Table 1, high stream velocities along the stream bank are frequently found beneath the bridges crossing the Grand River. The stream banks underneath the bridges are protected by concrete bridge abutments and do not require additional stream bank protection beyond that provided in the bridge design. The areas of most concern from a stream velocity and erosion standpoint are embankment sections where earth berms have been constructed atop natural stream banks at the river's edge (river edge Type 10, see Figure 2). Table 1 indicates that the embankment areas of the Grand River stream bank that are exposed to high water velocities during a 100-year flood and subject to erosion that could cause flooding are found at the following locations:

Left (East) Bank

- Cross-section 210918.9 to cross-section 211242.4 D – U.S. Route 131 Bridge downstream face to approximately 100 feet downstream of the bridge.
- Cross-section 216832.0 to cross-section 217611.5 – Approximately 20 feet downstream of the Newberry Street / 6th Street Bridge to about 775 feet upstream of the bridge.
- Cross-section 219837.8 to cross-section 221221.6 – Beginning about 580 feet upstream of the Leonard Street Bridge and extending about 850 feet along the embankment in the upstream direction.

Right (West) Bank

- Cross-section 212980.5 – Approximately 240 feet of stream bank immediately downstream of the Pearl Street Bridge.

The left (east) bank area of concern downstream of the U.S. Route 131 Bridge and the right (west) bank area downstream of the Pearl Street Bridge currently have riprap protection, which will be evaluated below. Although the areas along the left (east) bank upstream of the Newberry Street/6th Street Bridge and upstream of the Leonard Street Bridge are exposed to high velocity water, the banks are either lined with concrete retaining walls or dense vegetation and have not experienced any noticeable erosion during past flood events. The City will monitor these areas for possible problems in the future and will install riprap bank protection if necessary.

3.2 Grand River Levee Embankment Protection

Where riprap stream bank and embankment protection is provided in the as-built construction plans for GRFPS, it is specified as "heavy riprap" or just "riprap and broken masonry". Visual inspection of the riprap indicated that the riprap protection along the Grand River appears to conform to the MDOT *Standard Specifications for*

Construction, Section 916, Erosion and Sedimentation Control Materials. In the MDOT specifications, two sizes of riprap are identified as follows:

- Plain Riprap – natural stone and broken concrete with footprint dimensions ranging from 8 inches to 16 inches and an in-place thickness of at least 8 inches. Contractors may use smaller pieces to fill spaces between the larger pieces for better slope protection.
- Heavy Riprap – natural stone and broken concrete with a smallest footprint dimension of 16 inches, a maximum to minimum dimension ration of no greater than 3:1, and an in-place thickness of at least 8 inches.

The MDOT specifications do not indicate any stone size gradation, stone specific weight, stone durability requirements, bedding material requirements, and/or maximum slope requirements. The as-built plans for riprap covered slopes along the Grand River indicate that the existing riprap was either placed on prepared (i.e. graded and raked) slopes or atop geotextile filter fabric laid on prepared slopes. It should be noted that Michigan quarries sell riprap rock (generally limestone or dolomite) to contractors based on the two sizes in the MDOT specifications.

The evaluation of the adequacy of riprap protection depends on the resistance of individual riprap stones to displacement by water velocities. The calculations used to determine riprap adequacy rely on the riprap stone gradation and the properties of the riprap stone. Although the MDOT specifications do not provide guidance on riprap stone gradation and material characteristics, the MDEQ *Guidebook of Best Management Practices for Michigan Watersheds* provides guidance on riprap stream bank protection design. For this study, it was assumed that the MDEQ guidebook design parameters were used for the riprap stream bank protection used for the GRFPS.

Assuming that the MDOT riprap specifications conform to the MDEQ guidebook design parameters, an assumed riprap gradation was developed in which the MDOT riprap footprint dimension was designated to be the median riprap size (D_{50}). The D100 size (i.e. 100% of the riprap stone was finer by weight) was assumed to be 1.5 times the D_{50} particle size in accordance with the MDEQ guidelines. The particle size for MDOT cobblestone (3 inches to 12 inches) was assumed to be the D_{30} size (i.e. 30% of the riprap stone was finer by weight), and the particle size for MDOT coarse aggregate (¾ inch to 3 inches) was assumed to be the D_5 size (i.e.5% of the riprap stone was finer by weight). The assumed riprap gradations for the MDOT riprap types are listed in Table 2 and illustrated in Figure 3.

Table 2
Assumed Riprap Gradation Based on
MDOT Specifications and MDEQ Guidelines

Percent Lighter by Weight (%)	Weight of Stones (lbs)	
	Plain Riprap	Heavy Riprap
100	450	4,167
50	150	1,250
30	15	83
5	4	15

3.3 Riprap Evaluation

The USACE provides design guidance for levees including embankment protection in their Engineer Manual (EM) 1110-2-1913, *Design and Construction of Levees*, and EM 1110-2-1601, *Hydraulic Design of Flood Control Channels*. According to EM 1110-2-1601, Section 3.7, the riprap stone size should be determined using the following equation:

$$D_{30} = S_f \, C_S \, C_V \, C_T \, d \left[\left(\frac{\gamma_w}{\gamma_s - \gamma_w} \right)^{1/2} \frac{V}{\sqrt{K_1 \, g \, d}} \right]^{2.5} \quad (1)$$

Where: D_{30} = riprap size of which 30 percent is finer by weight, length

S_f = safety factor, assumed to be 1.5 to account for ice and debris impact

C_S = stability coefficient for incipient failure (see calculation below)

C_V = vertical velocity distribution coefficient

= 1.0 for straight channels

= 1.283 – 0.2 log (R/W), outside of bends for (R/W) ≤ 26, or = 1.0 if (R/W) > 26

where: R = centerline radius of bend in the main channel

W = water-surface width of bend in the main channel

C_T = thickness coefficient (see calculation below)

d = local depth of flow, ft (see calculation below)

γ_w = unit weight of water

= 62.4 lb/ft^3

γ_s = unit weight of riprap stone

= 165 lb/ft^3 (assumed limestone)

V = local depth-averaged velocity

= maximum velocity for each riprap protected section of stream bank and embankment from HEC-RAS results in Table 1

K_1 = side slope correction factor (see calculation below)

g = gravitational constant

= 32.16 ft/s^2

3.3.1 Stream Bank and Embankment Riprap Evaluation

The Grand River stream banks and embankments have partial or full height riprap protection in the areas identified in Item 3.0 that were constructed at different times by different contractors and now make up a portion of the GRFPS. For the analysis of the riprap adequacy, it was assumed that all of the riprap was full height on the embankment or stream bank slope. The following paragraphs discuss the determination of the variables used in Equation 1 for the full height riprap section evaluation.

C_S, Stability Coefficient Calculation

The values of the stability coefficient for incipient failure, C_S, tabulated in EM 1110-2-1601 are only applicable when D_{85}/D_{15} = 1.7 to 5.2 where D_{85} and D_{15} are the riprap stone sizes for which 85% and 15% of the diameters are smaller, respectively. For plain riprap, referring to Figure 3, the riprap stone weight for which 85% of the individual stones weigh less (W_{85}) was approximately 330 lbs, while the riprap stone weight for which 15% of the individual stones weigh less (W_{15}) was about 6.5 lbs. For heavy riprap, the D_{85} and D_{15} stone weights were approximately 2,800 pounds and 28 pounds, respectively.

The equivalent stone diameters for the W_{85} and W_{15} stone weights, D_{85} and D_{15} respectively, were calculated using the following equation from EM 1110-2-1601, Section 3-2:

$$D_{\%} = \left(\frac{6\,W_{\%}}{\pi\,\gamma_s}\right)^{1/3} \qquad (2)$$

For the D_{85} riprap stone size:

$$D_{85} = \left(\frac{6\,W_{85}}{\pi\,\gamma_s}\right)^{1/3} = \left(\frac{6\,W_{85}}{\pi\,(165)}\right)^{1/3}$$
$$= 1.56\ ft.plain\ riprap$$
$$= 3.19\ ft.heavy\ riprap$$

For the D_{15} riprap stone size:

$$D_{15} = \left(\frac{6\,W_{15}}{\pi\,\gamma_s}\right)^{1/3} = \left(\frac{6\,W_{85}}{\pi\,(165)}\right)^{1/3}$$
$$= 0.42\ ft.plain\ riprap$$
$$= 0.69\ ft.heavy\ riprap$$

Therefore:

$$\left(\frac{D_{85}}{D_{15}}\right)_{Plain} = \frac{1.56}{0.42} = 3.71 \qquad \left(\frac{D_{85}}{D_{15}}\right)_{Heavy} = \frac{3.19}{0.69} = 4.62$$

As calculated above, the ratios of D_{85}/D_{15} ratios for the as-built riprap are in the acceptable range for the stability coefficient for incipient failure. Therefore, because the D_{85}/D_{15} ratios were within the required range, the value of C_S = 0.30 for angular rock was used.

C_V, Vertical Velocity Distribution Coefficient

The Grand River is relatively straight through Grand Rapids except for a westward bend downstream of Fulton Street and a southward bend downstream of the southern I-196 crossing. There is no appreciable riprap protection at either of the bend locations. Therefore, the value of C_V was selected for straight channels:

$$C_V = 1.00$$

C_T, Thickness Coefficient Calculation

The thickness coefficient, C_T, is determined based on either the D_{100} or the D_{50} riprap stone diameter. From Figure 3, the W_{50} riprap stone weight was found to be 150 lbs for plain riprap and 1,250 lbs for heavy riprap while the W_{100} riprap stone weight was 450 lbs and 4,167 lbs, respectively. Using Equation 2 above, the D_{50} and D_{100} riprap stone sizes were calculated as follows:

$$D_{50} = \left(\frac{6\,W_{50}}{\pi\,\gamma_s}\right)^{1/3} = \left(\frac{6\,W_{50}}{\pi\ (165)}\right)^{1/3} = 1.20\ ft. and\ 2.44\ ft.$$

$$D_{50} = \left(\frac{6\,W_{100}}{\pi\,\gamma_s}\right)^{1/3} = \left(\frac{6\,W_{100}}{\pi\ (165)}\right)^{1/3} = 1.73\ ft. and\ 3.64\ ft.$$

According to EM 1110-2-1601, the value of C_T is based on a riprap layer thickness of either 1.0 D_{100}(max) or 1.5 D_{50}(max), whichever is greater. Thus, for the range of D_{50} and D_{100} riprap stone sizes:

$$1.0\ D_{100} = 1.73\ ft. and\ 3.64\ ft.$$

or

$$1.5\ D_{50} = 1.80\ ft. and\ 3.66\ ft.$$

According to the MDOT specifications, both plain and heavy riprap should have a minimum in-place thickness of 8 inches; however, according to the as-built plans, the riprap layer thickness was typically 16 inches. Thus, the ratio N of the actual riprap layer thickness to the maximum layer thickness provided by either 1.0 D_{100} or 1.5 D_{50} was:

$$N = \frac{Actual\ Riprap\ Layer\ Thickness}{1.5\ D_{50}} = \frac{1.33}{1.80} = 0.74\ for\ plain\ riprap$$

$$N = \frac{1.33}{3.66} = 0.36\ for\ heavy\ riprap$$

From Plate B-40 in Appendix B of EM 1110-2-1601 and assuming a value of D_{85}/D_{15} = 3.71 for MDOT plain riprap, a value of N = 0.74 was off the chart and the value of C_T was assumed to be that for a value of N=1.0 yielding C_T = 1.0. For MDOT heavy riprap with D_{85}/D_{15} = 4.62, the value of N = 0.36 was also off the chart; therefore, the same assumption was made, and the value of C_T = 1.0.

d, Local Depth of Flow Calculation

The areas of the Grand River with stream bank or embankment riprap are fairly steep with estimated slopes of 2H:1V. The depth of flow varies along the riprap protected stream banks and embankments.

In accordance with EM 1110-2-1601, the local depth of flow, d, is to be determined at a point 20% of the slope length from the toe of levee embankment slope. Referring to Figure 4, the angle for a 2H:1V slope is 26.57°.

From trigonometry, sin = b/c , from which c = b/sin is derived. A point 20% of the slope length from the toe of levee is illustrated by the length c' = 0.20 c. The height of the point 20% of the slope length from the toe of the levee measured from the bottom of the riprap protection is given by b' = c' sin (26.57°). Therefore, the local depth of flow was calculated as follows:

$$c = \frac{b}{\sin(26.57°)}$$

$$c' = 0.20\, c$$

$$b' = c' \sin(26.57°)$$

$$d = b - b'$$

For each of the riprap protected stream bank and embankment areas identified in Item 3.0, the local depth of flow, d, was calculated using the above equations and the average depth of flow along the protected stream banks and embankments from the HEC-RAS model results (Appendix 2). The results are shown in Table 3.

Table 3
Local Depth of Flow for Grand River
Riprap Protected Stream Banks and Embankments
Grand Rapids, Michigan

Riprap Protected Stream Reach	Average Depth of Flow, b (feet)	Local Depth of Flow, d (feet)
Left (East) Bank		
Station 129+47 to Station 133+77	23.10	18.48
Station 146+03 to Station 149+93	25.09	20.07

Station 395+79 to Station 399+79	15.98	12.78

K1, Side Slope Correction Factor Calculation

The side slope correction factor, K1, was calculated using the following equation from EM 1110-2-1601:

$$K_1 = \sqrt{1 - \frac{sin^2\theta}{sin^2\emptyset}} \quad (3)$$

where: θ = angle of side slope with horizontal (previously calculated to be 26.57°)

$\emptyset$ = angle of repose of riprap material (normally 40°)

Inserting the values of θ and $\emptyset$ in Equation 3 yields a value of $K_1 = 0.72$.

D30, Riprap Size Calculation

Inserting all of the values determined above in Equation 1 yields the D30 riprap sizes presented in Table 4:

Table 4
Summary of Calculations for D30 Particle Size
Riprap Embankment Protection
Grand River, Grand Rapids, Michigan

Station 395+79 to Station 399+79	1.5	0.30	1.00	1.0	12.78	62.4	165.0	3.92	0.72	32.16	0.08

From Table 1 and Figure 3, the D30 weight of the individual stones for MDOT specification plain and heavy riprap as developed using the MDEQ guidelines is 15 lbs and 83 lbs, respectively. Using Equation 2, the estimated stone diameters were calculated as follows:

$$D_{30} = \left(\frac{6\,W_{30}}{\pi\,\gamma_s}\right)^{1/3} = \left(\frac{6\,W_{30}}{\pi\,(165)}\right)^{1/3}$$

$$= 0.56\ ft.plain\ riprap$$

$$= 0.99\ ft.heavy\ riprap$$

The D_{30} sizes of the MDOT specification plain and heavy riprap, as developed based on the MDEQ BMP guidelines, exceeds the sizes required for the riprap stream bank and embankment protection locations along the Grand River listed in Table 4. Therefore, the existing riprap on the GRFPS embankment is adequate for the velocities expected during the 100-year flood.

4.0 Conclusions

The GRFPS has riprap stream bank and embankment protection at several locations along the Grand River to prevent erosion of the stream banks and embankment levee slopes and to prevent damage due to ice and debris impact. The gradation of the stones used for the riprap was developed using the MDOT *Standard Specifications for Construction* and the MDEQ *Guidebook of Best Management Practices for Michigan Watersheds* and confirmed by visual inspection of the riprap layers as well as a review of as-built plans for the project. The available riprap design information was sufficient to evaluate the adequacy of the riprap layer for the conditions resulting from a 100-year flood on the Grand River. The riprap stone size analysis presented in this report indicates that the existing riprap adequately protects the GRFPS from the river velocities and ice and debris impact resulting from a 100-year flood.

There are also sections of the stream bank and embankment sections along the Grand River in Grand Rapids that are not protected by floodwalls or riprap. An evaluation of stream velocities along the banks for a 100-year flood indicated only two areas where stream velocities were considered high enough to present a possible erosion hazard. In these areas, dense stream bank vegetation and concrete retaining walls have protected the stream banks from erosion during past flood events. The City will monitor these areas during future flood events and provide riprap protection, if necessary, to prevent erosion.

44 CFR 65.10(b) (1) (i) Tab

(1) *Freeboard.* (i) Riverine levees must provide a minimum freeboard of three feet above the water-surface level of the base flood. An additional one foot above the minimum is required within 100 feet in either side of structures (such as bridges) riverward of the levee or wherever the flow is constricted. An additional one-half foot above the minimum at the upstream end of the levee, tapering to not less than the minimum at the downstream end of the levee, is also required.

P.E. Signature: Peter W. Soltys

Non Applicable: See Below

P.E. Name: Peter W. Soltys

P.E. License Number and State: 037935 Michigan

Reaches E1, E2, E3, E4, W1, W2, W3, and W4 are Freeboard Deficient Reaches in accordance with FEMA's *Analysis and Mapping Procedures for Non-Accredited Levee Systems* dated July 2013 with the top of flood protection elevation above the Base Flood Elevation.

Reach E5 meets the freeboard requirements of 44 CFR 65.10(b) (1) (i).

44 CFR 65.10(b) (1) (ii) Tab

(ii) Occasionally, exceptions to the minimum riverine freeboard requirement described in paragraph (b)(1)(i) of this section, may be approved. Appropriate engineering analyses demonstrating adequate protection with a lesser freeboard must be submitted to support a request for such an exception. The material presented must evaluate the uncertainty in the estimated base flood elevation profile and include, but not necessarily be limited to an assessment of statistical confidence limits of the 100-year discharge; changes in stage-discharge relationships; and the sources, potential, and magnitude of debris, sediment, and ice accumulation. It must be also shown that the levee will remain structurally stable during the base flood when such additional loading considerations are imposed. Under no circumstances will freeboard of less than two feet be accepted.

Non Applicable: Peter W. Soltys

P.E. Name: Peter W. Soltys

P.E. License Number and State: 037935 Michigan

44 CFR 65.10(b) (1) (iii) Tab

(iii) For coastal levees, the freeboard must be established at one foot above the height of the one percent wave or the maximum wave runup (whichever is greater) associated with the 100-year stillwater surge elevation at the site.

P.E. Signature: _____

Non Applicable: Peter W. Soltys

P.E. Name: Peter W. Soltys

P.E. License Number and State: 037935 Michigan

44 CFR 65.10 (b) (1) (iv)

(iv) Occasionally, exceptions to the minimum coastal levee freeboard requirement described in paragraph (b)(1)(iii) of this section, may be approved. Appropriate engineering analyses demonstrating adequate protection with a lesser freeboard must be submitted to support a request for such an exception. The material presented must evaluate the uncertainty in the estimated base flood loading conditions. Particular emphasis must be placed on the effects of wave attack and overtopping on the stability of the levee. Under no circumstances, however, will a freeboard of less than two feet above the 100-year stillwater surge elevation be accepted.

Introduction

This report provides the results of a freeboard evaluation of the Grand Rapids flood protection system (GRFPS) based on crest elevation surveys conducted by Fishbeck. The Federal Emergency Management Agency (FEMA) and the Cities of Grand Rapids and Walker agreed to the division of the GRFPS into the reaches shown in Figure 1 for purposes of evaluation per the requirements of 44 CFR 65.10. In terms of the freeboard requirements of 44 CFR 65.10 (b)(1)(i), only the reach along the east bank of the Grand River at the Water Resource Recovery Facility (WRRF) identified as Reach E5 meets the sound reach freeboard requirements. However, all of the other reaches discussed below provide protection from the 100-year flood elevation with varying levels of freeboard. For these reaches, Grand Rapids and Walker are seeking Freeboard Deficient Reach certification.

Description

The reaches of the Grand River Flood Protection System (GRFPS), shown in Figure 1, are along the Grand River and Indian Mill Creek in Grand Rapids, Michigan and consist of the following:

- Reach E1 – Knapp Street downstream to Leonard Street.
  - 5,260 feet of natural ground topped by former railroad embankment.
  - 630 feet of natural ground.
- Reach E2 – Leonard Street downstream to Interstate Route 196 (I-196)
  - 3,520 feet of earth embankment inland from river edge retaining wall.
  - 560 feet of floodwall and concrete bridge abutments.
  - 750 feet of natural ground
- Reach E3 – Gillett Pedestrian Bridge downstream to US 131.
  - 1,215 feet of floodwall and concrete bridge abutments between Fulton and Bridge Streets
  - 1,280 feet of natural ground much of which is above high river edge retaining walls
- Reach E4 – US 131 to the end of the floodwall 2,880 feet downstream of Wealthy Street
  - 790 feet of earth embankment
  - 4,250 feet of floodwall and concrete bridge abutments.
- Reach E5 – Ring levee around the Water Resources Recovery Facility (WRRF)
  - 7,630 feet of earth embankment levee.
- Reach W1 – City Boundary downstream to Indian Mill Creek including left (north) bank of Indian Mill Creek from Grand River to second upstream railroad crossing.
  - 6,150 feet of natural ground along the Grand River and Indian Mill Creek
  - 3,060 feet of floodwall along the Grand River and Indian Mill Creek
- Reach W2 – Confluence of Indian Mill Creek to I-196 including right (south) bank of Indian Mill Creek from Grand River to second upstream railroad crossing.
  - 6,130 feet of floodwall and concrete bridge abutments along the Grand River and Indian Mill Creek
  - 3,655 feet of earth embankment along the Grand River and Indian Mill Creek
  - 390 feet of natural ground along the Grand River

- Reach W3 – I-196 downstream to Fulton Street
  - 2,405 feet of earth embankment
  - 215 feet of concrete bridge abutment
  - 1,300 feet of natural ground
- Reach W4 – Fulton Street downstream to the West End Ditch
  - 1,970 feet of earth embankment
  - 3,970 feet of floodwall and concrete bridge abutments

The reaches of the GRFPS contain natural ground, earth embankments, railroad embankments, bridge abutments, and floodwalls that were constructed and/or maintained by Grand Rapids and Walker to meet or exceed the level of the base 100-year return interval flood.

100-Year Water Surface Profile

The original Flood Insurance Rate Map (FIRM) for the City of Grand Rapids (City) was dated November 5, 1982 and Flood Boundary Floodway Map (FBFM) was dated January 17, 1979. The 100-year flood and floodway boundaries were developed from a river model prepared using U.S. Geological Survey (USGS) computer programs E431 *Computer Applications for Step-Backwater and Floodway Analyses* and J635 *Step-Backwater and Floodway Analyses*. The elevations in the USGS model were referenced to the National Geodetic Vertical Datum of 1929 (NGVD29). In 2008 FEMA introduced a new model of the Grand River from the downstream Kent County boundary to the upstream City boundary using the U.S. Army Corps of Engineers (USACE) HEC-RAS River Analysis System program. This model included all the former river cross-sections from the original USGS Grand River model plus additional surveyed cross-sections, and referenced the elevation data to the North American Vertical Datum of 1988 (NAVD88). The conversion of the NGVD29 datum to the NAVD88 datum used the following equation:

$$\text{NAVD88} = \text{NGVD29} - 0.45 \text{ feet}$$

In discussions between FEMA, the City and Fishbeck following release of the 2008 HEC-RAS model, it was agreed that the model should be extended to Lake Michigan by including previously developed HEC-RAS models for the Grand River communities downstream of Kent County. The resulting Grand River HEC-RAS model was completed in 2010. Subsequent corrections to cross-section geometry were accepted by Fishbeck resulting in the HEC-RAS model dated July 2015. Finally, the 2009 change in the NAVD88 datum for western Michigan of -0.13 feet was incorporated into the model in December 2017. The December 2017 HEC-RAS model results for 100-year water surface profile are included in Appendix 1. The initial survey of the GRFPS crest elevation was performed by Fishbeck in the period 2008-2009. In subsequent years, Grand Rapids and Walker made improvements to the floodwalls, earth embankments, and road grades with the locations shown in Figure 2. In the period 2016-2017 the GRFPS was resurveyed to document the freeboard improvements. The survey point numbers and survey dates are identified in Tables 1 through 9.

Freeboard

Freeboard – Reaches E1, E2, E3, E4, W1, W2, W3, and W4

According to 44 CFR 65.10(b)(1)(i), the required freeboard (additional height above the regulatory flood elevation) for riverine levees must be 3-feet above the 100-year flood water surface elevation (Base Flood Elevation, BFE) with an additional 1-foot within 100-feet of a structure (e.g. bridge) and an additional 0.5-foot at the upstream end of the levee tapering to the minimum 3-feet of freeboard at the downstream end of the system.

Under the provisions of FEMA's Analysis and Mapping Procedures for Non-Accredited Levee Systems, dated January 2016, the City is seeking Freeboard Deficient Reach status for Reaches E1, E2, E3, E4, W1, W2, W3, and W4 of the GRFPS. For Freeboard Deficient Reach status, the following conditions must be met:

- The flood protection floodwalls and embankments (levees) and any closure structures within the effective reaches must be above the Base Flood Elevation (BFE) defined as the 100-year return interval flood elevation.
- An Operations and Maintenance Plan covering the effective reaches must meet the standards of 44CFR65.10(c).
- The structural design of floodwalls and levees within the effective reaches must meet the design standards for closures in 44CFR65.10(b)(2).

The 100-year flood elevations and GRFPS crest elevations for each reach are presented in Tables 1 through 4 and 6 through 9 and the resulting profiles are shown in Figures 3 through 6 and 8 through 11. Note that in Reach W2, the flood protection crest elevation at river station 216020.2 in Fish Ladder Park reflects the crest of the closure structure at this location (see Closure Analysis Report). A 10-foot-wide by 5-foot-tall closure structure will be installed during extreme floods. In Reach W4 the flood protection crest elevation at river station 209683.80 at the CSX bridge abutment reflects the crest of the closure structure at this location. A 40-foot-wide by 1.5-foot-tall closure structure will be installed during extreme floods.

Freeboard – Reach E5

The ring levee around the WRRF, Reach E5, meets the freeboard requirements for 44 CFR 65.10(b)(1)(i); therefore, the City is seeking full accreditation as a Sound Reach for this reach.

The crest elevations for the ring levee are presented in Table 5 and the 100-year flood and levee crest elevation profiles are shown in Figures 7A through 7D.

Conclusion

The crest elevations of the entire lengths of all reaches of the GRFPS are above the BFE except as noted above for Reach W2 and W4. Reaches E1, E2, E3, E4, W1, W2, W3, and W4 do not meet freeboard requirements for riverine levees provided in 44 CFR 65.10(b)(1)(i); however, these reaches all have flood protection above the BFE. At this time, the City is seeking Freeboard Deficient Reach certification for these reaches.

Reach E5 consists of the ring levee around the WRRF. This levee fully meets the requirements of 44 CFR 65.10(b)(1)(i); therefore, the City requests full accreditation as a Sound Reach for this levee.

Notes:
1. River stations in blue were determined by extending a line from a surveyed bank elevation perpendicular to the centerline of the Grand River. The centerline of the Grand River was stationed in the HEC-RAS model based on the distance in feet from the mouth at Lake Michigan.
2. All elevations in orange were interpolated from the HEC-RAS 100-year flood profile or the river bank surveyed point elevations.

Notes:

1. River stations in blue were determined by extending a line from a surveyed bank elevation perpendicular to the centerline of the Grand River. The centerline of the Grand River was stationed in the HEC-RAS model based on the distance in feet from the mouth at Lake Michigan.
2. All elevations in orange were interpolated from the HEC-RAS 100-year flood profile or the river bank surveyed point elevations.
