Notes:
1. River stations in blue were determined by extending a line from a surveyed bank elevation perpendicular to the centerline of the Grand River. The centerline of the Grand River was stationed in the HEC-RAS model based on the distance in feet from the mouth at Lake Michigan.
2. All elevations in orange were interpolated from the HEC-RAS 100-year flood profile or the river bank surveyed point elevations.

Notes:
1. River stations in blue were determined by extending a line from a surveyed bank elevation perpendicular to the centerline of the Grand River. The centerline of the Grand River was stationed in the HEC-RAS model based on the distance in feet from the mouth at Lake Michigan.
2. All elevations in orange were interpolated from the HEC-RAS 100-year flood profile or the river bank surveyed point elevations.

Notes:
1. River stations in blue were determined by extending a line from a surveyed bank elevation perpendicular to the centerline of the Grand River. The centerline of the Grand River was stationed in the HEC-RAS model based on the distance in feet from the mouth at Lake Michigan.
2. All elevations in orange were interpolated from the HEC-RAS 100-year flood profile or the river bank surveyed point elevations.

211912.72		YES - Contract No. 2 (2016)	610.15	612.05	----	Interpolated	0.01	1.88	583.58	610.17

Notes:
1. River stations in blue were determined by extending a line from a surveyed bank elevation perpendicular to the centerline of the Grand River. The centerline of the Grand River was stationed in the HEC-RAS model based on the distance in feet from the mouth at Lake Michigan.
2. All elevations in orange were interpolated from the HEC-RAS 100-year flood profile or the river bank surveyed point elevations.
3. Elevations in red indicate the need for a closure structure at a railroad bridge. The City is in negotiations with CSX Corporation to construct a closure structure by the end of June 2018 that will provide a minimum 100-year flood level of protection. Until the closure structure in constructed, temporary closure methods, such as a sandbag wall, will be used.

Appendix 1

100-Year Water Surface Profile HEC-RAS Results

44 CFR 65.10 (b) (4) Tab

(4) *Embankment and foundation stability.*
Engineering analyses that evaluate levee embankment stability must be submitted. The analyses provided shall evaluate expected seepage during loading conditions associated with the base flood and shall demonstrate that seepage into or through the levee foundation and embankment will not jeopardize embankment or foundation stability. An alternative analysis demonstrating that the levee is designed and constructed for stability against loading conditions for Case IV as defined in the U.S. Army Corps of Engineers (COE) manual, ''Design and Construction of Levees'' (EM 1110–2–1913, Chapter 6, Section II), may be used. The factors that shall be addressed in the analyses include: Depth of flooding, duration of flooding, embankment geometry and length of seepage path at critical locations, embankment and foundation materials, embankment compaction, penetrations, other design factors affecting seepage (such as drainage layers), and other design factors affecting embankment and foundation stability (such as berms).

44 CFR 65.10 (b) (5) Tab

(5) *Settlement.* Engineering analyses must be submitted that assess the potential and magnitude of future losses of freeboard as a result of levee settlement and demonstrate that freeboard will be maintained within the minimum standards set forth in paragraph (b)(1) of this section. This analysis must address embankment loads, compressibility of embankment soils, compressibility of foundation soils, age of the levee system, and construction compaction methods. In addition, detailed settlement analysis using procedures such as those described in the COE manual, ''Soil Mechanics Design— Settlement Analysis'' (EM 1100–2–1904) must be submitted.

Attention: Mr. James E. Smalligan, P.E.
Senior Vice President

Reference: Embankment and Foundation Stability and Settlement Analysis Report
Grand River Floodwall and Embankment Stability
Grand Rapids, Michigan

Dear Mr. Smalligan:

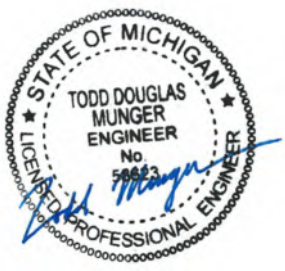
We have completed geotechnical engineering services related to the stability evaluation of the existing floodwalls and embankments in the City of Grand Rapids. Results of the study are presented in the attached report. This report supersedes our report dated March 16, 2018 and addresses comments in the FEMA Completeness Check and Comment letter dated May 3, 2019.

There are no significant indications of global or structural instability, excessive projected settlement or seepage of the existing floodwalls and embankments. Stability evaluations confirm acceptable factors of safety.

We appreciate this opportunity to provide engineering services to you. Please contact our office should you have any questions or require further assistance.

Sincerely,

MATERIALS TESTING CONSULTANTS, INC.



Todd D. Munger, P.E.

EMBANKMENT AND FOUNDATION STABILITY AND SETTLEMENT ANALYSIS REPORT GRAND RIVER FLOODWALL AND EMBANKMENT STABILITY GRAND RAPIDS, MICHIGAN

1.0 INTRODUCTION

The City of Grand Rapids (City) has retained Fishbeck, Thompson, Carr & Huber, Inc. (FTCH) to undertake an assessment of the flood protection system along the Grand River as required by Federal Regulation (44CFR65.10). FTCH has retained Materials Testing Consultants, Inc. (MTC) to perform specific stability evaluations as required by the referenced Federal Regulation. Descriptions of the study methods and results are provided herein for the flood protection system. This work has been performed as described in our proposal dated June 12, 2012. This report supersedes our report dated March 16, 2018 and addresses comments in the FEMA Completeness Check and Comment letter dated May 3, 2019.

The scope of this study, in-general, includes the following:

- Task 1 - Information gathering and review of available existing information. Review available historic information including soil test boring logs, reports and as-built floodwall drawings. Conduct a walkover survey of the floodwalls and embankments to identify indications of global and structural instability.
- Task 2 - Perform foundation stability analyses as required by Paragraph 65.10.b.4 and settlement analyses as required by Paragraph 65.10.b.5 of the referenced Federal Regulation.
- Task 3 - Preparation of this report.

Presented herein are descriptions of background information pertaining to the study, the investigation methodology, investigation results, and conclusions. The Appendices contain boring location plans, boring logs and laboratory test data (Appendix A), engineering evaluations (Appendix B) and historic water level data (Appendix C).

1.1 Background

The Grand River flood protection system was constructed through numerous initiatives dating back to the late 1800's. Since that time and extending into the first two decades of the 1900's, a majority of the existing flood protection was constructed. Numerous modifications and improvements have been made on both private and public properties since the original construction. Flood protection within the system is comprised of both floodwalls and embankments. Floodwalls include gravity walls, cantilever walls, counterfort walls, hybrid walls containing properties of several wall types in addition to an integral floodwall-trunk sewer. A majority of the floodwalls were constructed using concrete, however, several of the gravity walls utilized stone and mortar construction methods as was popular in the late 1800's and early 1900's.

On October 6, 1989, Wade-Trim Associates submitted a report to the City entitled *The Grand River Floodwall/Embankment Study* providing a summary of the flood protection with respect to the 100-year flood elevation, the degree of scour based on wall probing, the structural condition of the floodwalls, outlets requiring back-flow control, areas where permanent or temporary pump facilities were needed as well as freeboard recommendations. In July 1995, FTCH submitted a report to the City entitled *The Grand River Floodwall & Embankment Improvements Implementation Plan* which presented alternatives and recommendations for flood protection improvements based on a review of the 1989 Wade-Trim study and a supplemental field investigation performed by FTCH considering 1982 FEMA 100-year flood elevations. Necessary increases in floodwall and embankment heights were discussed in the FTCH report in addition to recommendations corresponding to maintenance of existing floodwalls and storm water management. Maintenance and improvements to the Grand River flood protection system occurred in the following years based on recommendations in the 1995 FTCH report.

Development of the 2010 FEMA base flood model and subsequent 2015 FEMA base flood model for the Grand River in Grand Rapids has resulted in a general increase in the FEMA Base Flood Elevation (BFE) within the City limits. As a result of the increase, several areas of existing flood protection were deemed to no longer meet freeboard requirements per the referenced Federal Regulation. Certification of the Grand River flood protection system within the City of Grand Rapids based on "freeboard deficient" criteria has prompted the current study.

FTCH performed a comprehensive survey of the pipe penetrations and backflow prevention measures within the Grand River flood protection system and have divided the system into a series of reaches located both west and east of the Grand River which require some level of flood protection (embankment or floodwall) to protect upland areas below the base flood elevation. The reaches are shown on the attached Study Area Location Plan, Figure No. 1 and are summarized below:

East Side of Grand River

- Reach E1 – Knapp Street downstream to Leonard Street
- Reach E2 – Leonard Street downstream to Interstate Route 196 (I-196)
- Reach E3 – Gillett Pedestrian Bridge downstream to U.S. Route 131 (US 131)
- Reach E4 – US 131 downstream to 50% distance to the Water Resource Recovery Facility (WRRF)
- Reach E5 – WRRF Boundary

West Side of Grand River

- Reach W1 – U.S. Route 131 ramp crossing of railroad track in the City of Walker downstream to Indian Mill Creek and then up Indian Mill Creek along the north bank for approximately 2,400 feet to the second railroad bridge
- Reach W2 – Down Indian Mill Creek along the south bank from second railroad bridge crossing for approximately 2,400 feet to the confluence with the Grand River and then downstream to I-196
- Reach W3 – I-196 downstream to Fulton Street
- Reach W4 – Fulton Street downstream to the Butterworth Landfill

2.0 INVESTIGATION METHODOLOGY

2.1 Compilation and Review of Existing Information

Compilation and review of available existing information and conditions included researching our archive files and reviewing the provided existing floodwall and embankment drawings. Relevant boring logs, piezometer data and geotechnical reports were assembled and reviewed for projects performed within the study area. In total, over 600 logs from soil borings performed within the City limits adjacent to the Grand River, Plaster Creek and Indian Mill Creek were reviewed dating back to 1969. Location plans of the borings are included as Figures A-1 through A-14 in Appendix A as well as boring logs specific to stability analysis sections within each reach. We also reviewed drawings of the floodwall system, dating from 1909 to 1998, from City archives provided by FTCH as well as drawings pertaining to recent flood protection improvements prepared by FTCH in 2016.

2.2 Walkover Survey

Upon review of the available existing information, a walkover survey was conducted of the flood protection system to identify flood protection systems and representative sections for stability analyses and apparent indications of structural or global instability. The walkover survey was conducted by Mr. Steven M. Elliott, P.E. and Mr. Todd D. Munger, P.E. of MTC between October 23, 2012 and November 8, 2012. Our walkover survey did not include an assessment of internal structural stability, such as concrete strengths or size and spacing of reinforcing steel. Modifications to the flood protection system were designed by FTCH to address areas with protection below the base flood elevation as well as O&M issues. These modifications are reflected in the 2016 flood protection improvement drawings.

2.3 Subsurface Conditions

During the development of the area in the late 1800's and early 1900's, placement of available miscellaneous material was common to raise low-lying riverbank levels, to create additional property for development as well as flood protection for nearby residences and businesses, defining what is now the current river boundary. A majority of the existing riverbanks are therefore composed of miscellaneous fill material extending to depths up to 20 or 30 ft.

The miscellaneous fill material is composed of a primarily granular soil with occasional cohesive soil, boulder and cobble, organic material (topsoil, peat and wood), building debris, cinders, brick and the like. Directly adjacent to and within the river channel, granular glacial outwash and post-glacial alluvium are present below the miscellaneous fill material below which relatively shallow bedrock is present as previously discussed. Native cohesive soil is also encountered adjacent to and within the river channel most often in the form of highly weathered shale above more competent shale and gypsum. The bedrock is typically highly weathered near the top of rock with frequent fractures which transitions to more competent (massive) rock with depth.

Six supplemental conventional soil test borings (Borings B-1 through B-6, MTC Project No. 111266) were performed along with one hand auger boring (Boring B-5HA) within Reaches E1, W1, W2 and W4. In addition, 22 supplemental soil test borings (B-1 through B-22, MTC Project No. 111266.2) were completed around the perimeter of the embankment protecting the WRRF within Reach E5. These borings were completed where historical subsurface data was lacking and supplemental subsurface information was required. Flood protection improvements, including modifications described in Section 3.2, were completed following the completion of supplemental borings, however, the soil boring information utilized, and associated analyses are appropriately representative of the existing condition of the flood protection system.

A select number of representative samples collected from the borings were subjected to laboratory testing to approximate or confirm the engineering properties of the soil. Laboratory testing performed included the following:

- ASTM D 422 "Test Method for Particle-Size Analysis of Soils"
- ASTM D 4318 "Test Method for Liquid Limit, Plastic Limit and Plasticity Index of Soils"
- ASTM D 2216 "Method for Laboratory Determination of Water (Moisture) Content of Soil, Rock, and Soil-Aggregate Mixtures"
- ASTM D 1140 "Test Method for Material in Soils Finer than the No. 200 (75-µm) Sieve"
- ASTM D 2974 "Test Methods for Moisture, Ash, and Organic Matter of Peat and Other Organic Soils"
- ASTM D 3080 "Test Method for Direct Shear Test of Soils Under Consolidated Drained Conditions"
- USACE Method EM 1110-IV-1906 “Falling-Head Permeability Test with Permeameter Cylinder”

Index testing including particle size analysis, Atterberg Limits, moisture content and organic matter content were performed on a select number of samples to revise the field classification (ASTM D 2488) to the more refined ASTM D 2487 Standard Practice Classification of Soils for Engineering Purposes where appropriate. A summary of the laboratory test results and the individual laboratory test reports are provided in Appendix A.

2.4 Stability Analyses

The stability of the flood protection system was evaluated through the selection of representative embankment and floodwall sections within each reach with well documented geometries. With stability analysis sections selected, FTCH surveyed floodwall and embankment geometries at each section and provided the collected information to MTC including the 2015 BFE. Analyzed cross-sections represent existing conditions as described herein. The following table provides a summary of the location and flood protection type at stability evaluation sections.

Table 2.4.1 - Embankment and Floodwall Stability Section Summary

Embankment and foundation stability analyses are required by Paragraph 65.10.b.4 of the referenced Federal Regulation. Specifically, the regulation requires seepage analyses and stability

evaluations during loading cases associated with the base flood. U.S. Army Corps of Engineers (COE) Manual "Design and Construction of Levees" (EM 1110-2-1913), Chapter 6, Section 2 is referenced by the regulation which provides required factors of safety associated with the loading cases under consideration. The loading cases and the corresponding required factors of safety are provided in Table 2.4.2.

Table 2.4.2 - Levee Stability Criteria (EM 1110-2-1913)

Case	Loading Description	Required Factor of Safety
Case I	Existing Condition	1.3
Case II	Sudden Drawdown	1.0 to 1.2
Case III	Steady State Seepage (BFE)	1.4
Case IV	Earthquake	> 1.0

For the Case I loading, effective stress parameters were utilized for both granular and cohesive soils while for Case II, III and IV loading, total stress parameters were used for cohesive soil to reflect the shear strength of the soil under short-term loading conditions.

In consideration of the presence of both embankment protection as well as floodwall protection within the flood protection system, the U.S. Army Corps of Engineers (COE) Manual "Retaining and Flood Walls" (EM 1110-2-2502) was reviewed for inland floodwall stability criteria. Required factors of safety and minimum eccentricities associated with four loading cases are provided in Table 4-2 of the manual and are summarized below in Table 2.4.3.

Table 2.4.3 - Inland Floodwall Stability Criteria (EM 1110-2-2502)

Case	Loading Description	Sliding and Global FS	Minimum Base Area in Compression, % (soil)	Minimum Base Area in Compression, % (rock)	Bearing Capacity FS
Case I1	Design Flood	1.50	100	75	3.0
Case I2	Water to top of wall	1.33	75	50	2.0
Case I3	Earthquake	1.10	Resultant within base	Resultant within base	>1.0
Case I4	Construction	1.33	75	50	2.0

Embankment and Floodwall Global Slope Stability

Global slope stability was evaluated considering failure towards the river for each of the four loading cases stipulated in EM 1110-2-1913 for both embankments and floodwalls. Slope failure away from the river (landside) was also evaluated considering steady state seepage conditions during the base flood and was found to not control given the relatively high landside elevation with respect to the top of flood protection.

Computer software SLIDE 6.0 was utilized to perform limit equilibrium slope stability analyses at the section locations. The Modified Bishop Method was utilized to compute the factor of safety against global slope stability failure for the four loading cases considered.

Earthquake Load Case

ER 1110-2-1806 is referenced by EM 1110-2-1913 for earthquake design and evaluation. Although no specific factor of safety is provided in the reference regarding earthquake loading, the reference states that the project "team is responsible for establishing the earthquake engineering requirements for the project, planning and executing the seismological and engineering investigations, and evaluating the results." The reference also describes that detailed site explorations, site-specific ground motion studies, and structural analyses are not necessary for projects located in Zones 0 and 1 and that preliminary values of the ground motions obtained from published seismic zone maps may be used to determine if seismic loading controls the design and to set the scope of any proposed site-specific studies. The study area is in Zone 0 with a very low risk for seismic activity and, therefore, it is considered that a detailed site exploration and determination of site-specific ground motions will not be necessary and a pseudostatic analysis will be sufficient.

The pseudostatic method is an inertial analysis method originally applied by Terzaghi (1950) where the cyclic nature of the earthquake is ignored, and the earthquake loading is applied as an additional static force acting through the centroid of the mass under consideration. The horizontal pseudostatic force (F_h) acts to decrease stability while the vertical pseudostatic force (F_v) typically has less impact on stability and is frequently neglected. The horizontal pseudostatic force acting upon the mass is equal to the product of the total weight of the mass (W) and the horizontal

pseudostatic coefficient (k_h) where k_h is equal to the maximum horizontal acceleration (a_{max}) divided by the acceleration due to gravity (g).

Per Kramer (*Geotechnical Earthquake Engineering*, Prentice Hall, 1996), psuedostatic coefficients used in practice generally correspond to acceleration values well below a_{max} because the body of mass is typically not rigid, and the peak acceleration occurs only for a very short time period. Kramer references a study performed by Hynes-Griffin and Franklin (1984) which concluded that earth dams with pseudostatic factors of safety greater than 1.0 using $k_h = 0.5a_{max}/g$ should not develop "dangerously large" deformations.

Conservatively, the peak ground acceleration (PGA) can be selected for a_{max} if the maximum horizontal acceleration is unknown. United States Geological Survey (USGS) 2008 Earthquake Hazard Maps of the Central/Eastern United States were used to select a PGA for the study area corresponding to an earthquake with a 10 percent probability of exceedance in 50 years (CEUS PGA 10%/50 years, 2008). A PGA of 2% g (0.02g) was selected. The PGA associated with 2 percent probability of exceedance in 50 years in the study area is also very near 2% g. The pseudostatic coefficient was then computed as follows:

$$k_h = 0.5 \times \frac{a_{max}}{g} = 0.5 \times \frac{0.02g}{g} = 0.01 .$$

Therefore, significant deformations are not anticipated when using a horizontal pseudostatic coefficient of 0.01 and where static stability safety factors are greater than 1.0.

Floodwall External Stability

With respect to floodwall stability, sudden drawdown is expected to represent the most critical load case due to the potential instability created by unbalanced hydrostatic pressure behind the floodwall, however, EM 1110-2-2502 makes no reference to the specific evaluation of a sudden drawdown load case for inland floodwalls. Due to the stabilizing effect of the hydrostatic pressure acting on the waterside of the floodwall during the design flood and the inconsequential impact of earthquake loading considering a factor of safety of 1.0 or greater is estimated, the suggested floodwall stability analysis procedure was modified to analyze the stability associated with the following load cases: (1) existing condition and (2) sudden drawdown.

As no specific "existing condition" or "sudden drawdown" analysis criteria are provided for floodwalls, floodwall stability was evaluated based on the criteria summarized below in Table 2.4-4, incorporating stability components of both EM 1110-2-1913 and EM 1110-2-2502.

Table 2.4.4 - Modified Inland Floodwall Stability Criteria

Case	Loading Description	Sliding and Global FS	Minimum Base Area in Compression (soil), Percent	Minimum Base Area in Compression (rock), Percent	Bearing Capacity FS
Case I	Existing Condition	1.3	75	50	2.0
Case II	Sudden Drawdown	1.0	Resultant within base	Resultant within base	>1.0

Sudden Drawdown

Per EM 1110-2-1913, sudden drawdown represents an analysis condition whereby a prolonged flood stage saturates at least a major part of the upstream embankment (or floodwall backfill) and then falls faster than the soil can drain, resulting in full-height unbalanced water head conditions which occur instantaneously without consideration of expected drawdown rates. Federal Regulation (44CFR65.10) states levee embankment stability analyses must be submitted based on ***expected*** seepage during loading conditions associated with the base flood. Based on historic water level measurements and observations during drawdown events, we conclude, as described herein, it is unrealistic to apply full-height sudden drawdown parameters when evaluating floodwall stability as this condition is not applicable to the Grand River flood protection system.

In order to estimate expected drawdown rates and the corresponding expected drawdown loading condition upon embankments and floodwalls, Grand River level data was collected and reviewed against landside groundwater level data collected from piezometers installed behind floodwalls as well as within flood protection embankments. Piezometer locations are summarized in Table 2.4.5.

Table 2.4.5 - Historical Piezometer Location Summary

Project/Event	Year	Purpose
Convention Center	2000	Monitor groundwater immediately behind floodwall
Plaza Towers	2013	Monitor groundwater during 2013 Grand River flood event
GVSU Eberhard	2017	Monitor groundwater levels within embankment protection

Piezometer locations are provided in Figure C-1 located within Appendix C. Figures C-2, C-3 and C-4 (Appendix C) provide a graphical representation of landside groundwater and Grand River water levels as a function of time and provide insight into the groundwater behavior adjacent to the river during river flood and drawdown events. Of particulate importance, Figure C-3 includes data collected during the 2013 Grand River flood event where the river crested at a historic high of 21.85 ft (el 607.55) in downtown Grand Rapids.

Each high river event was prompted by significant regional precipitation resulting in prolonged high river levels with the peak river crest followed immediately by negligible regional precipitation resulting in drawdown. River level data confirms that instantaneous drawdown does not occur within the system but, rather, river levels decrease at a maximum drawdown rate of 1 to 2 ft per day when considering weather conditions which would facilitate maximum drawdown. Piezometer data concludes landside groundwater elevations immediately behind floodwalls and within embankments closely follow adjacent Grand River water levels. Landside groundwater levels were found to react to river level drawdown almost immediately with groundwater elevations measured to be within approximately 1 to 3 ft of adjacent river levels at each measurement interval.

Considering the similarity in subsurface conditions and associated drainage properties throughout the system and historical water level data presented, we conclude full-height sudden drawdown loading conditions are not applicable to the Grand River flood protection system as expected seepage during river drawdown results in a “controlled” drawdown rate with a maximum head differential of 3 ft. As a result, a more appropriate “controlled” drawdown condition was evaluated whereby a maximum allowable head differential was calculated for each floodwall section required to maintain a stable condition and compared to the expected maximum head differential of 3 ft to confirm minimum stability requirements.

Steady State Seepage – Embankments, Floodwalls

Steady state seepage was analyzed during the base flood event at each section with the exception of floodwalls bearing upon or within bedrock where excessive seepage is not expected. At locations where seepage faces were predicted to form on the landside of the flood protection, the critical hydraulic gradient (i_{cr}) was analyzed to evaluate the likelihood of piping or heave. Computer software SLIDE 6.0 was utilized to perform finite element steady state seepage analyses (where appropriate) at the section locations. Steady state seepage analyses were performed for the base flood which evaluated the steady state groundwater surface behind the floodwall or embankment, the hydraulic gradient and the presence of potential seepage faces where applicable.

Steady State Seepage – Outfalls

Per Paragraph 65.10.b.2 of the referenced Federal Regulation, "all outfalls must be provided with closure devices that are structural parts of the system during operation and design according to sound engineering practice." In the City of Grand Rapids flood protection system, all outfalls with inlets below the base flood elevation have backflow prevention (closure devices) in the form of flap gates, valves, duckbills or sluice gates, most of which are mounted to a floodwall or headwall on the riverside of the flood protection. Headwalls have wing walls designed to protect flap gates from ice damage that has commonly been experienced in the past. When it is not feasible to construct a headwall, backflow prevention is provided in manhole structures on the landside of the flood protection. This has proven to be an effective measure against ice damage while allowing for more efficient inspection and maintenance.

It has been the City's practice to not install backflow prevention (closure devices) on outfalls with inlets above the BFE. These outfalls serve either upland areas above the BFE, roof drains or have inlets only on the riverside of the levee. Prior to 1980, it was standard practice to grout sealed pipe joints to prevent leakage. Since 1980, rubber O-ring gasketed joints have been used. The flood protection at these outfall locations are either floodwalls or broad earthen embankments with a protected landside ground surface less than 4 ft below the BFE. No instability related to seepage from these pipes has been reported in the past.

To demonstrate potential seepage associated with outfalls which do not contain riverside closure devices will not jeopardize the stability of the flood protection system, four steady state seepage

outfall analysis locations were evaluated (Outfalls 29, 48, 56 and 112). Analysis locations were originally numbered by FTCH and were selected to evaluate large diameter pipes which do not contain modern rubber gasketed joints with limited ground cover relative to the adjacent BFE. FTCH provided cross sections and pipe diameters to assist in the development of each seepage model. A total water head equal to the adjacent river BFE was considered within each pipe extending from the outlet to landward of the flood protection (embankment or floodwall) to model a pipe hydraulically connected to the river. Although a structurally sound pipe with intact joints is not expected to result in excessive seepage forces, the risk of instability was evaluated by modeling a failure at the pipe crown consisting of a 6-inch wide opening and the corresponding exit hydraulic gradient at the ground surface adjacent to the flood protection system was analyzed using SLIDE 6.0 software. The risk of instability (piping or heave) was evaluated by comparing the estimated exit hydraulic gradient (i) to the critical hydraulic gradient (i_{cr}). A summary of analysis locations is provided in Table 2.4.6.

Table 2.4.6 - Outfall Steady State Seepage Analysis Section Summary

Reach	Section	Pipe Type	Flood Protection Type
E1	Outfall 56	48-inch RCP Storm Sewer (1936)	Embankment
W2	Outfall 112	42-inch RCP Storm Sewer (1963)	Floodwall
E2	Outfall 48	54-inch RCP Storm Sewer (1962)	Embankment / Floodwall
E3	Outfall 29	60-inch RCP Storm Sewer (1991)	Embankment

Settlement

Settlement analyses are required by Paragraph 65.10.b.5 of the referenced Federal Regulation. Specifically, the regulation requires an assessment of the potential and magnitude of future losses of freeboard as a result of settlement based on guidance referenced in COE Manual "Engineering and Design – Settlement Analysis" (EM 1110-1-1904).

At each stability evaluation section, settlement and the potential impact due to loss of freeboard was evaluated considering total settlement (immediate settlement, primary consolidation, secondary consolidation and decomposition of organic material where applicable) based on the subsurface conditions encountered in adjacent soil borings or supplemental borings which can be found in Appendix A for reference. Immediate settlement in granular soil was estimated utilizing

the Hough Method while consolidation settlement in cohesive soil was estimated utilizing one-dimensional consolidation theory. Cohesive soil was conservatively considered to be normally consolidated. Where organic soil was encountered, settlement associated with secondary consolidation and decomposition of organic material was estimated considering a 100-year design life. The load increase considered at each stability evaluation section is summarized in Table 2.4.7 and is based on information contained in provided flood protection improvement drawings provided by FTCH and described in Section 3.2

Table 2.4.7 – Settlement Analysis Summary

Reach	Section	Flood Protection Type	Recent Flood Protection Improvements	Proposed Load Increase (psf)
E1	E1A	Embankment	None	0
	E1B	Embankment	None	0
E2	E2A	Embankment	None	0
	E2B	Embankment / Floodwall	Increase embankment height by 2 ft	240
E3	E3	Counterfort Floodwall	None	0
E4	E4	Floodwall and Trunk Sewer	None	0
E5	E5	Embankment	Increase embankment height by average of 1.5 ft	180
W1	W1	Cantilever Floodwall	None	0
W2	W2A	Embankment	None	0
	W2B	Gravity / Cantilever Floodwall	None	0
	W2C	Gravity Floodwall	None	0
W3	W3	Embankment	Increase embankment height by 1.5 ft	180
W4	W4A	Counterfort Floodwall	Increase top of floodwall by 1 ft	12
	W4B	Embankment	None	0

3.0 INVESTIGATION RESULTS

3.1 Walkover Survey

In general, no obvious signs of structural or global instability were identified during our walkover survey of the existing floodwalls and embankments. Based on observations during the survey, a brief description of observed flood protection within each reach is summarized in Table 3.1.1.

Table 3.1.1 - Reach Flood Protection Summary

Reach	Flood Protection
E1	Embankments along the east bank of the Grand River
E2	Combination of embankments north of the 6th Street Dam and a cantilever and gravity retaining wall south of the 6th Street Dam to immediately south of I-196
E3	Floodwalls including concrete cantilever and counterfort walls and gravity stone and mortar walls. A 300 ft length of the river's edge located immediately north of the Blue Bridge is protected by the west exterior concrete foundation and masonry building wall of 55 and 85 Campau Avenue NW.
E4	Embankments provide most the flood protection within the northern half of Reach E3 with the southern half protected by an integral floodwall and trunk sewer structure
E5	Embankments provide flood protection around the perimeter of the WRRF with respect to the adjacent Grand River and Plaster Creek with additional groundwater control provided by groundwater pumping within the WRRF property
W1	Embankments and concrete cantilever retaining walls
W2	Counterfort, gravity and cantilever retaining walls. The southern and northern extents of the reach are protected by embankments.
W3	Natural ground elevations as well as embankments
W4	A counterfort retaining wall provides flood protection within the northern half of the reach with the southern half protected by embankments.

3.2 Flood Protection Modifications

Following the walkover survey, flood protection modifications and improvements were designed and implemented by FTCH and the City to provide freeboard equal to or above the base flood elevation, repair aging infrastructure and install backflow prevention onto existing storm sewer penetrations. A summary of individual flood protection improvement contracts is provided:

- Improvements to berms at the Wastewater Treatment Plant
- Contract No. 1 – Backflow prevention improvements throughout flood protection system
- Contract No. 2 – Freeboard and Embankment Protection Improvements
  - Concrete retaining wall construction at 700 Wealthy Street, 624 Front Avenue, 2204 to 2280 Turner Avenue, 509 Wealthy Street, 201 Market and 647 Monroe Avenue

  - Sheet pile wall installation at 509 Wealthy Street
  - Increase embankment height up to approximately 2 ft at 647 Monroe Avenue and 1781 Broadway Avenue
  - Floodwall cap construction up to approximately 15-inches in height placed at 50 and 210 to 240 Front Street, 417 Watson Street, 449 Market and 201 Market
  - Storm sewer and flap gate installation at 1781 Broadway Avenue
- Contract No. 3 – Freeboard and embankment protection improvements at 58 and 220 Front Avenue and 272 Pearl Street including concrete retaining wall construction, reconstruction of Indian Mounds Park and increasing the embankment height by 1.5 ft at Ah Nab Awen Park.

In addition to the described flood protection modifications to satisfy freeboard deficient criteria, FTCH has updated the Grand Rapids Flood Protection System Emergency Action Plan containing provisions for strategic permanent closures during flood stage above the BFE. Although supplemental soil borings were performed prior to flood protection modifications, the soil boring information utilized, and associated analyses reflect the existing condition of the flood protection system as described herein.

3.3 Regional Geology

The *Map of the Surface Formations of the Southern Peninsula of Michigan*, published by the State of Michigan, indicates the site is in an area of glacial outwash. The Grand River valley is known to have been a major channel of glacial water flows. Near-surface soil conditions typically are found to be primarily granular with numerous cobbles and boulders. Several areas along the west and east riverbanks are known to have been low-lying areas prior to development of the area and have been filled with a variety of uncontrolled urban fill materials.

Relatively shallow bedrock is present below the Grand River within Grand Rapids which includes a limestone and sandstone cap of the Bayport Formation north of the Lyon Street alignment. Near the Lyon Street alignment, the Bayport Formation ends, and the underlying weathered shale and gypsum of the Michigan Formation continues south below overburden soil. Near Pearl Street and south where the Bayport Limestone is absent, the Michigan Formation Shale is approximately 10 to 30 ft below the riverbed.

3.4 Supplemental Test Borings

The subsurface conditions in the supplemental soil borings confirm the presence of miscellaneous fill material along floodwalls and within embankments overlying granular and cohesive soil and bedrock. The miscellaneous fill material typically consists of variable granular soil with occasional cinders, wood fragments, brick and topsoil-like material. The most commonly encountered granular soils included *poorly graded sand* (SP), *poorly graded sand with silt* (SP-SM), *poorly graded sand with clay* (SP-SM), *silty sand* (SM) and *clayey sand* (SC) while the most commonly encountered cohesive soil was *lean clay* (CL).

Reaches E1, W1, W2 and W3

Six conventional soil test borings, Borings B-1 through B-6 (MTC Project No. 111266), were performed behind floodwalls and near the top of embankments to obtain subsurface information at Sections W3, W2C, E1B, E1A, W2A and W1, respectively, where existing subsurface information was not available or was incomplete for stability analysis purposes. A hand auger boring (Boring B-5HA) was performed to evaluate the material near a railroad embankment (Section W2A) where drill rig access was not possible.

Borings B-1 through B-3 and B-6 were extended to refusal at depths varying from 13.5 to 25.1 ft on bedrock or possible boulder/cobble while Borings B-4 and B-5 were performed to a depth of 40 ft below existing grade. The very dense gravel and silt material encountered near the explored depth at Borings B-1 and B-4 may represent a stratum of highly weathered bedrock material overlying more competent bedrock.

At Boring B-3, approximately 5.5 ft of black loose *poorly graded sand* (SP), anticipated to be composed primarily of cinders, was encountered overlying approximately 7.5 ft of dark brown to black very loose *silty sand with gravel* (SM) topsoil. Bedrock was encountered at approximately 13 ft. The cinder material was likely placed as railroad embankment over the topsoil fill material prior to track placement.

Table 3.4.1 provides a summary of the subsurface conditions encountered at supplemental boring locations performed within Reaches E1, W1, W2 and W3.

Table 3.4.1 - Supplemental Soil Boring Summary

Boring No.	Stability Section No.	Ground Surface Elev. (ft)	Boring Depth (ft)	Groundwater Elev. (ft)	Fill Depth (ft)	Bedrock Elev. (ft)
B-1	W3	611.29	25.1	596.3	17	NA
B-2	W2C	611.73	14.1	606.2	11	598.7
B-3	E1B	614.73	13.5	606.8	13	601.7
B-4	E1A	618.42	40.0	604.4	12	NA
B-5	W2A	613.79	40.0	605.8	8	NA
B-5HA	W2A	NA	8.7	NA	NA	NA
B-6	W1	614.44	18.5	606.4	5.5	NA

Reach E5

Twenty-two conventional soil test borings, Borings B-1 through B-22 (MTC Project No. 111266.2) were performed along the perimeter of the embankment protecting Reach E5, encountering variable layers of uncontrolled fill overlying layers of native clay, silt and sand, in-turn overlying shale and gypsum bedrock. Intermediate strata of silt, peat, and gravel were occasionally encountered. The peat deposits were encountered in Borings B-18 and B-22 near the southeast corner of the property at a depth close to the normal water level of the Grand River and the original ground surface elevation of the site prior to development. Wood fragments and roots were noted in the fill. Wood (presumably a fallen tree beneath the fill) was found in Boring B-13 between the 12 and 15 ft depth.

Bedrock, varying from weathered shale to fragmented gypsum, was encountered at elevations between el 564 and el 589. Most borings had some samples with poor recovery, possibly due to the presence of coarse gravel or cobbles. Boring B-3 experienced auger refusal at 26.5 ft deep, in a gravel stratum. Boring B-4A, completed with a hand auger, was abandoned at 4.5 ft due to auger refusal, likely caused by cobbles. Boring B-8 experienced auger refusal at 5 ft and cobble was present in the auger cuttings at the point of refusal.

Groundwater was encountered between el 576 and el 595 ft. It should be noted that groundwater levels measured during drilling are influenced by the amount of pumping within the WRRF property, adjacent river and creek levels and other factors.

The described relative density of the granular soil is based on the SPT N-values while the estimated unconfined compressive strength of cohesive soil (provided in the logs) is based on calibrated penetrometer readings. The boring logs located in Appendix A should be reviewed for detailed soil descriptions as deviations from the provided descriptions do exist.

Groundwater levels measured during drilling are influenced by adjacent river and creek levels which vary with several factors. Water levels will vary with time.

3.5 Laboratory Test Results

Laboratory testing was performed on select soil samples to validate soil properties utilized in stability analyses. A summary of notable laboratory results is provided herein. A comprehensive summary of laboratory data is provided in Appendix A.

Reaches E1, W1, W2 and W3

Direct Shear Testing (ASTM D 3080) was performed on samples of granular fill material collected at Borings B-1, B-3 and B-4. Effective friction angles and effective cohesion through Direct Shear Testing ranged from approximately 44 to 51 degrees and 0.063 to 0.182 tsf.

Organic Content Testing (ASTM D 2974) confirmed the presence of organic material at Borings B-3 and B-4. The dark brown to black *silty sand with gravel* (SM) fill encountered at Boring B-3 was determined to have an organic content of 8.5 percent and likely represents an assortment of miscellaneous material including topsoil and granular soil which was used to fill the area. At Boring B-4, the gray *sandy organic clay* (OH) was determined to have an organic content of 9.4 percent and likely was once near or at the former ground surface prior to fill placement.

Reach E5

Permeability testing on 15 soil samples yielded hydraulic conductivities ranging from $1.1x10^{-5}$ to $1.2x10^{-2}$ cm/s. Direct Shear Testing on two samples of granular fill material collected from Borings B-12 and B-14 yielded effective friction angles and effective cohesion ranging from approximately 28.2 to 43.4 degrees and 0.176 to 0.375 tsf.

The laboratory effective friction angles were significantly higher than the effective friction angles utilized in our stability analyses. Effective cohesion within the granular fill material was not considered in our stability analyses.

3.6 Stability Analyses

Results of stability analyses are provided herein with comprehensive results for slope stability, floodwall stability, steady state seepage and settlement as well as geotechnical parameters considered organized by reach provided in Appendix B.

Global Slope Stability

A summary of estimated global slope stability factors of safety is provided in Table 3.6.1.

Table 3.6.1 - Global Slope Stability Summary

Reach	Section	Flood Protection Type	Global Factor of Safety			
			Case I Existing Condition	Case 2 Sudden Drawdown	Case 3 Steady State Seepage	Case 4 Earthquake
E1	E1A	Embankment	1.31	1.72	5.83	2.15
	E1B	Embankment	2.43	1.07	2.35	2.22
E2	E2A	Embankment	2.44	1.90	3.43	2.25
	E2B	Embankment / Floodwall	1.99	1.21	2.54	1.94
E3	E3	Counterfort Floodwall	1.79	1.09	2.42	1.76
E4	E4	Floodwall and Trunk Sewer	2.80	>10	>10	>10
E5	E5	Embankment	1.70	1.50	1.80	1.70
W1	W1	Cantilever Floodwall	2.15	1.00	3.44	2.08
W2	W2A	Embankment	2.76	1.75	2.72	2.63
	W2B	Gravity / Cantilever Floodwall	2.32	1.78	4.98	2.27
	W2C	Gravity Floodwall	2.54	2.03	5.33	2.48
W3	W3	Embankment	3.42	1.77	4.06	3.42
W4	W4A	Counterfort Floodwall	1.78	1.08	5.11	1.74
	W4B	Embankment	2.23	1.25	2.67	2.14

Global slope stability evaluations confirm acceptable factors of safety considering existing conditions, sudden drawdown, steady state seepage and earthquake loading cases. The minimum global factor of safety for sudden drawdown at Section W1 is equal to 1.00 which meets the minimum recommended factor of safety for existing levees per Table 6.1b of EM 1110-2-1913 and captures the most critical factor of safety for the existing conditions in Reach W1.

Floodwall External Stability

Results of floodwall external stability evaluations are provided below in Table 3.6.2.

Table 3.6.2 - Floodwall External Stability Summary

Reach	Section	Flood Protection Type	Load Case	Hydro. Head Diff. (ft)	Base Area In Comp. (%)	FS Bearing	FS Over-turning	FS Sliding
E2	E2B	Embankment and Cantilever Floodwall	EC	0.0	100	>3	5.10	2.68
			SD	8.0	Resultant within Base	>3	1.00	1.14
E3	E3	Counterfort Floodwall	EC	0.0	100	>3	5.91	2.16
			SD	14.0	64	>3	1.42	1.05
E4	E4	Floodwall and Trunk Sewer	EC	0.0	100	>3	3.02	2.00
			SD	6.7	100	>3	1.48	1.00
W1	W1	Cantilever Floodwall	EC	0.0	100	>3	17.88	9.05
			SD	5.5	100	>3	4.77	3.00
W2	W2B	Gravity / Cantilever Floodwall	EC	0.0	90	>3	6.35	2.44
			SD	7.5	Resultant within Base	>3	1.01	1.19
	W2C	Gravity Floodwall	EC	0.0	89	>3	1.57	2.06
			SD	3.0	Resultant within Base	>3	1.00	1.56
W4	W4A	Counterfort Floodwall	EC	0.0	100	>3	4.55	1.86
			SD	8.3	71	>3	1.61	1.00

Existing floodwalls meet stipulated factors of safety associated with slope stability (Table 3.6.1), bearing and sliding as well as the percent of base area in compression considering the existing condition (EC) load case.

The calculated maximum allowable head differential required to maintain a stable floodwall condition meets or exceeds the maximum measured head differential of 3 ft based on historic water level measurements with justification for a "controlled" drawdown rate analysis provided in Section 2.4. Existing floodwalls are judged to be stable with respect to sudden drawdown.

Steady State Seepage – Embankments, Floodwalls and Outfalls

Steady state seepage conclusions are provided in Table 3.6.3.

Table 3.6.3 - Steady State Seepage Summary

Reach	Section	Flood Protection Type	Seepage Analysis Performed	Seepage Faces Present on Landside of Protection	i / i_{cr}	Piping/ Heave Expected
E1	E1A	Embankment	Yes	Yes	0.12 / 0.84	No
	E1B	Embankment	Yes	No		No
	Outfall 56	Embankment	Yes	Yes	0.39 / 0.84	No
E2	E2A	Embankment	Yes	No		No
	E2B	Embankment / Floodwall	Floodwall Bears on Bedrock			No
	Outfall 48	Embankment / Floodwall	Yes	Yes	0.25 / 0.84	No
E3	E3	Counterfort Floodwall	Yes	No	0.50 / 0.84	No
	Outfall 29	Embankment	Yes	No		No
E4	E4	Floodwall and Trunk Sewer	Floodwall Bears on Bedrock			No
E5	E5	Embankment	Yes	Yes	0.15 / 0.84	No
W1	W1	Cantilever Floodwall	Yes	No		No
W2	W2A	Embankment	Yes	No		No
	W2B	Gravity / Cantilever Floodwall	Floodwall Bears on Bedrock			No
	W2C	Gravity Floodwall	Floodwall Bears on Bedrock			No
	Outfall 112	Gravity Floodwall	Yes	Yes	0.20 / 0.84	No
W3	W3	Embankment	Yes	Yes	0.17 / 0.84	No
W4	W4A	Counterfort Floodwall	Yes	No		No
	W4B	Embankment	Yes	No		No

Steady state seepage evaluations conclude piping and heave is not expected to occur as a result of excessive seepage forces. The seepage analyses performed are judged to be applicable to all pipe penetrations not equipped with flag gates and which have outlet elevations below the BFE and invert elevations above the BFE. Based on our understanding of the conditions as described, pipe penetrations within the system will not jeopardize the stability of the flood protection system.

Settlement

Table 3.6.4 provides a summary of the magnitude of future losses of freeboard as a result of settlement at each analysis section. A stress increase corresponding to flood protection improvements completed or planned in the future was utilized to evaluate the magnitude of future settlement (immediate settlement, primary consolidation, secondary consolidation and decomposition of organic material). A design life of 100 years was considered for secondary consolidation calculations.

Table 3.6.4 - Settlement Summary

Reach	Section	Flood Protection Type	Estimated Future Settlement (in)
E1	E1A	Embankment	2.9
	E1B	Embankment	4.1
E2	E2A	Embankment	0.0
	E2B	Embankment / Floodwall	0.7
E3	E3	Counterfort Floodwall	0.0
E4	E4	Floodwall and Trunk Sewer	1.5
E5	E5	Embankment	1.9
W1	W1	Cantilever Floodwall	0.0
W2	W2A	Embankment	0.0
	W2B	Gravity / Cantilever Floodwall	0.0
	W2C	Gravity Floodwall	0.0
W3	W3	Embankment	0.6
W4	W4A	Counterfort Floodwall	0.1
	W4B	Embankment	4.4

The soil borings utilized, and associated analyses reflect the existing conditions of the flood protection system. Although some future settlement of embankments and floodwalls is expected, our analyses conclude minimum freeboard requirements will be maintained.

Materials Testing Consultants, INC.

Boring Log Terminology

Soil Classification Systems:

ASTM D2487 Standard Classification of Soils for Engineering Purposes (Unified Soil Classification System)
ASTM D2488 Standard Practice for Description and Identifications of Soils (Visual-Manual Procedure)

Minor Component Quantifying Terms:

Trace (less than 5%); Few (5 to 10%); Little (15 to 25%); Some (30 to 45%); Mostly (50 to 100%)

Sample Types and Numbering:

S	SPT, split-barrel sample, ASTM D1586	**U**	Shelby tube sample, ASTM D1587
***S**	Other than 2" split barrel sample	**A**	Auger cuttings
L	SPT with liner, ASTM D1586	**R**	Rock core run
		G	Geoprobe liner

Grain Size:

Boulder	>12"
Cobble	12" to 3"
Coarse Gravel	3" to 0.75"
Fine Gravel	0.75" to No. 4
Coarse Sand	No. 4 to No. 10
Medium Sand	No. 10 to No. 40
Fine Sand	No. 40 to No. 200

Clay - Soil passing a No. 200 sieve that can be made to exhibit plasticity (putty-like properties) and exhibits considerable strength when air dry (ASTM D2487).
Silt - Soil passing a No. 200 sieve that is nonplastic or very slightly plastic and exhibits little or no strength when air dry (ASTM D2487).
Peat - A soil composed of decomposed vegetable tissue with organic odor, dark brown to black color, spongy consistency, and a fibrous to amorphous texture.

"Grades with" or "Grades without" may be used to describe soil when characteristics vary within a stratum.

Moisture Condition:. Dry (absence of visible moist.); Moist (damp but no visible water); Wet (visible free water)

Compactness (Coarse Grained Soils) and Consistency (Fine Grained Soils):

N-value	Relative Density	Compactness	N-value	Approx. Shear Strength, ksf	Consistency
0 - 4	0 - 20%	Very Loose	0 - 2	0.25	Very Soft
5 - 10	20 - 40%	Loose	3 - 4	0.25 - 0.5	Soft
11 - 30	40 - 70%	Med. Dense	5 - 8	0.5 - 1	Med. Stiff
31 - 50	70 - 90%	Dense	9 - 16	1 - 2	Stiff
>50	90 - 100%	Very Dense	17 - 32	2 - 4	Very Stiff
			>32	>4	Hard

Groundwater Observations:

During - indicates water level encountered during the boring
End - indicates water level immediately after drilling
Date and Depth - Measurements at indicated date

Water observations in pervious soils are considered reliable for the date. Water observations in impervious soils may not be accurate groundwater measurements unless records are made over several days time. Groundwater levels will fluctuate for both pervious and impervious soils.

Materials Testing Consultants, INC.

ASTM D2488 Soil Classification Chart - Coarse Grained Soil:

Primary Soil Type	Group Name and (Group Symbol)	Criteria
GRAVEL	Well-graded GRAVEL (GW) Poorly graded GRAVEL (GP)	<5% fines, <15% sand
	Well-graded GRAVEL with sand (GW) Poorly-graded GRAVEL with sand (GP)	<5% fines, >15% sand
	Well-graded GRAVEL with silt (GW-GM) Poorly graded GRAVEL with silt (GP-GM) Well-graded GRAVEL with clay (GW-GC) Poorly-graded GRAVEL with clay (GP-GC)	10% fines, <15% sand
	Well-graded GRAVEL with silt and sand (GW-GM) Poorly graded GRAVEL with silt and sand (GP-GM) Well-graded GRAVEL with clay and sand (GW-GC) Poorly graded GRAVEL with clay and sand (GP-GC)	10% fines, >15% sand
	Silty GRAVEL (GM) Clayey GRAVEL (GC)	>15% fines, <15% sand
	Silty GRAVEL with sand (GM) Clayey GRAVEL with sand (GC)	>15% fines, >15% sand
SAND	Well-graded SAND (SW) Poorly-graded SAND (SP)	<5% fines, <15% gravel
	Well-graded SAND with gravel (SW) Poorly-graded SAND with gravel (SP)	<5% fines, >15% gravel
	Well-graded SAND with silt (SW-SM) Poorly-graded SAND with silt (SP-SM) Well-graded SAND with clay (SW-SC) Poorly-graded SAND with clay (SP-SC)	10% fines, <15% gravel
	Well-graded SAND with silt and gravel (SW-SM) Poorly-graded SAND with silt and gravel (SP-SM) Well-graded SAND with clay and gravel (SW-SC) Poorly-graded SAND with clay and gravel (SP-SC)	10% fines, >15% gravel
	Silty SAND (SM) Clayey SAND (SC)	>15% fines, <15% gravel
	Silty SAND with gravel Clayey SAND with gravel	>15% fines, >15% gravel

Materials Testing Consultants, INC.

ASTM D2488 Soil Classification Outline - Fine Grained Soil:

Primary Soil Type	Group Name and (Group Symbol)	Criteria
SILT	SILT (ML) Elastic SILT (MH)	<15% plus No. 200
	SILT with sand (ML) Elastic SILT with sand (MH)	15-25% plus No. 200, % sand > % gravel
	SILT with gravel (ML) Elastic SILT with gravel (MH)	15-25% plus No. 200, % gravel >% sand
	Sandy SILT (ML) Sandy Elastic SILT (MH)	>30% plus No. 200, % sand > % gravel, <15% gravel
	Sandy SILT with gravel (ML) Sandy Elastic SILT with gravel (MH)	>30% plus No. 200, % sand > % gravel, >15% gravel
	Gravelly SILT (ML) Gravelly Elastic SILT (MH)	>30% plus No. 200, % gravel > % sand, <15% sand
	Gravelly SILT with sand (ML) Gravelly Elastic SILT with sand (MH)	>30% plus No. 200, % gravel > % sand, >15% sand
CLAY	Lean CLAY (CL) Fat CLAY (CH)	<15% plus No. 200
	Lean CLAY with sand (CL) Fat CLAY with sand (CH)	15-25% plus No. 200, % sand > % gravel
	Lean CLAY with gravel (CL) Fat CLAY with gravel (CH)	15-25% plus No. 200, % gravel >% sand
	Sandy lean CLAY (CL) Sandy fat CLAY (CH)	>30% plus No. 200, % sand > % gravel, <15% gravel
	Sandy lean CLAY with gravel (CL) Sandy fat CLAY with gravel (CH)	>30% plus No. 200, % sand > % gravel, >15% gravel
	Gravelly lean CLAY (CL) Gravelly fat CLAY (CH)	>30% plus No. 200, % gravel > % sand, <15% sand
	Gravelly lean CLAY with sand (CL) Gravelly fat CLAY with sand (CL)	>30% plus No. 200, % gravel > % sand, >15% sand

Note: Percentages are based on estimated amounts of fines, sand and gravel to the nearest 5%

SUMMARY OF LABORATORY TEST DATA

Boring Number	Sample No. *	Sample Depth (ft)	Sample Description and USCS Classification	Effective Friction Angle (degrees)	Effective Cohesion (tsf)	Natural Moisture Content (%)	Organic Content (%)	Atterberg Limits		
								LL	PL	PI
B-1	A-1	2 - 3	Dark Brown Silty Sand with Gravel	46.2	0.182	16.4				
B-3	A-2	2 – 2.5	Black Poorly Graded Sand with Silt and Gravel							
B-3	A-5	7 – 7.5	Dark Brown to Black Silty Sand with Gravel	51.7	0.063	34.0	8.5	45	34	11
B-4	A-2	2 – 2.5	Brown Silty Sand with Gravel	44.7	0.121	7.9				
B-4	S-6	13.5 – 15	Gray Sandy Organic Clay				9.4	69	40	29
B-4	S-7	18.5 - 20	Light Gray Silty Sand

SLIDEINTERPRET 6.039B

REACH E1, SECTION E1A - SETTLEMENT ANALYSIS.
Proposed Condition
Boring B-4 (111266)

Immediate Settlement - Granular Soil (Hough Method)h

$$\Delta H_i = H_c \frac{1}{C'} \log\left(\frac{\sigma'_o + \Delta\sigma_v}{\sigma'_o}\right)$$

Primary Consolidation - Cohesive Soil (One-dimensional consolidation theory)h

$$S_c = \left[\frac{H_c}{1+e_o}\right]\left[C_c \log \frac{\sigma'_f}{\sigma'_p}\right]$$

Secondary Consolidation - Organic Soilh

$$S_s = \frac{C_\alpha}{1+e_p} H_c \log\left(\frac{t_2}{t_1}\right)$$

Organic Decompositionh
Consider settlement percentage due to decomposition of organic material equal to loss of 1/2 percent of organics by weigh

GW EL =		*Groundwater elevationh*
σ (psf) =		*Proposed load increaseh*

Introduction

The construction of flood protection works along the Grand River in Grand Rapids, Michigan began as early as 1899 with a floodwall constructed to protect the City lighting plant and crematoria. Following the flood of record in March 1904 and another flood in June 1905, the City of Grand Rapids (City) funded construction of flood walls including a wall that extended from a point 3/4 mile north of Leonard Street to the south end of Market Avenue on the east side of the river and from north of Leonard Street to the Wealthy Street Bridge on the west side. This construction occurred in the period 1907 through 1910. Over the years since then, a variety of floodwalls, earth berms, storm water collection systems and pump stations, and backflow prevention measures have been constructed along both banks of the Grand River within the City limits. The most recent floodwall improvements were made in the period 1998 to 2008, and the most recent pump station improvements were made to the Market Avenue Pump Station in 2008. For levee/floodwall certification under the provisions of 44 CFR 65.10, the Grand Rapids Flood Protection System (GRFPS) was divided into a series of reaches as shown in Figure 1. Note that Reach W1 extends into the City of Walker that drains, in part, to the Indian Mill Creek Pump Station in Grand Rapids. Improvements to the Turner Avenue road grade, storm sewers, and backflow prevention devices on pipes that penetrate Turner Avenue were made in 2016 to provide flood protection to the interior areas of Walker.

The Grand Rapids storm water collection system consists of various drains and street inlets, storm sewers, and pipe penetrations through the earth levee and concrete floodwall portions of the project. Backflow through the majority of the active drain pipes is prevented by flap gates, duckbill valves, and sluice gates on the outlet ends of the pipes or in upstream manholes and in a few cases by manual closure methods that are incorporated into the GRFPS Emergency Action Plan. There are several outfall pipes without flap gates or other backflow prevention measures at the outfall locations because they serve only upland areas above the base flood elevation (BFE). In these cases, manholes located downstream of the upland areas have bolt-down manhole lids to prevent flood waters from lifting the covers causing street flooding. When storm water runoff cannot fully drain from the collection system due to flood levels on the Grand River it backs up into the wet wells of six storm water pump stations or is stored in the collection system until the river level has receded. Figures 11 through 19 show the collection system drainage area upstream of each of the 9 designated reaches along the east and west banks of the Grand River and the downstream portion of Indian Mill Creek.

Note that the City is currently seeking freeboard deficient reach status for all but Reach E5, as provided by the Federal Emergency Management Agency's (FEMA) Analysis and Mapping Procedures for Non-Accredited Levee Systems, dated July 2013. Therefore, all drainage pipes listed in the Closure Analysis Report as having "inlets above the BFE" have no inlets below base flood elevation, but the inlet elevations may not always meet the freeboard requirements of 44 CFR 65.10.

Fishbeck prepared this analysis of the interior drainage system for the GRFPS on behalf of the City. Because the topography of Grand Rapids and levels in the Grand River vary so much dependent upon location, each of the pump station service areas were analyzed as a separate drainage basin having its own unique flood frequency dependent on high water levels. The analysis was prepared in accordance with the methodology presented in the U.S. Army Corps of Engineers (USACE) Engineering and Design Manual EM 1110-2-1413 Hydrologic Analysis of Interior Areas dated January 15, 1987.

Flood Prone Areas

The GRFPS serves approximately 1,420 acres on the right (west) bank and 195 acres on the left (east) bank of residential, commercial, institutional, and industrial properties within the City boundaries from high water in the Grand River. The protection system also provides pumping capacities, storm water interceptors, and gravity outfalls to discharge interior runoff during a rainfall event. Except for small areas with shallow flooding less than 1 foot of depth, all flood prone areas are served by a storm water pump station. These are:

- Wealthy Street Pump Station – On the right (west) bank downstream of the Oxford Street Trail Bridge.
- Market Avenue Pump Station – On the left (east) bank immediately north of the Oxford Street Trail Bridge.
- Front-Scribner Pump Station – On the right (west) bank immediately upstream of the Interstate Route 196 (I-196) Bridge and just downstream of the 6th Street Dam and fish ladder.
- Caledonia Street Pump Station – On the left (east) bank between the Grand River and Monroe Avenue at Caledonia Street extended.
- Palmer Street Pump Station – On the left (east) bank between the Grand River and Monroe Avenue at Palmer Street extended.
- Indian Mill Creek Pump Station – On the left (north) bank of Indian Mill Creek on the south side of Ann Street and just east of the intersection of Will Avenue and Ann Street.

Table 1 shows the individual pump capacity for each of these pump stations.

Table 1
Grand Rapids Flood Protection System
Pump Characteristics

Pump Station	Number of Pumps	Single Pump Capacity (gpm)	Station Capacity (cfs)	Station Capacity Return Interval (years)*
Indian Mill Creek	3	4500	30	25
Palmer Street	3	4500	30	100
Caledonia Street	3	4500	30	10
Front & Scribner	6	53125	710	50
Wealthy Street	10	53125	1184	100
Market Avenue	4	10770	96	10
* Refer to Table 4 for peak storm water runoff estimates for each pump station drainage basin.				

Because the topography of Grand Rapids and levels in the Grand River vary dependent upon location, each of the pump station service areas were analyzed as a separate drainage basin. Each of the pump stations is automatically controlled and begins pumping when water in its respective wet well reaches a float activator at a pre-set level. Under normal (non-flood) conditions, storm water flows through each pump station without overflowing into the pump station wet wells. When water levels in the Grand River rise, flap gates on the various storm sewer outlets along the floodwalls and levees of the GRFPS as well as the flow through conduits in the pump stations close causing water to back up into the pump station wet wells. Each pump discharge line also has a check valve to prevent backflow through the pump. Figures 11 through 19 show the pump station service areas.

Storm water runoff in each drainage basin was assumed to flow through levees and floodwalls in the existing drainage pipes until the Grand River level reached top of pipe elevation at the outlet thereby shutting the flap gates. When the flow in the drainage pipes backed up due to flap gate closure, the pump station was assumed to run. The invert elevations for each of the storm water outfalls along the Grand River in each pump station watershed and the 1 percent annual chance flood elevation at the outfalls are shown in Table 2. The storm water outfall locations are shown on Figures 2 through 10.

A comparison of the invert elevations (plus the outfall/flap gate vertical dimension) to the 1 percent annual chance flood elevation (base flood elevation) for each outfall in Table 2 indicates that all the pump station bypass pipes and storm sewer outfalls along the Grand River will be closed for the base flood except for those outfalls serving only upland areas above the base flood elevation.

Table 2
Base Flood and Backflow Prevention Operations Elevations

Outfall Identification Number	Number of Flap Gates*	Outfall/Flap Gate Size	1 Percent Annual Chance Flood Elevation (feet, NAVD88)	Flood Gate Invert Elevation (feet, NAVD88)
Wealthy Street Pump Station Watershed – Reach W4				
72G Pump Station Bypass Conduits	3	8 feet x 8 feet	608.34	585.34
72G Pump Station Discharge Conduits	10	54-inch diameter	608.34	598.75
96	1	30-inch diameter	610.09	591.87
105A	1	24-inchdiameter	612.18	591.73
Market Avenue Pump Station Watershed – Reach E4				
---	0	**	608.54	595.87
** All storm water in the watershed is routed to an outflow chamber adjacent to the pump station. When the Grand River exceeds elevation 596.00 feet, storm water flowing into the siphon outlet for the outflow chamber exceeds the crest elevation of a weir wall that separates the storm water outflow chamber from the pump station wet well. At this point, a sluice gate in the outflow chamber closes preventing river water from entering the wet well. All of the storm water then flows into the pump station wet well to be pumped into the portion of the outflow chamber that discharges into the siphon outlet.				
Front/Scribner Pump Station Watershed – Reach W2				
107B Pump Station Bypass Conduits	3	6 feet x 6 feet	612.80	595.27

*For outfalls with 0 flap gates, the manholes along the drainage pipe network upstream of the outfall have bolt-down castings to prevent overflow onto the streets to the point where the pipe inverts are above the 1 percent annual chance flood elevation.

Reach E1, which includes the Caledonia Street and Palmer Street Storm Water Pump Stations which discharge to the Grand River through Outfalls 56B, 61 and 61A also has outfalls that serve small localized areas that do not drain to the pump stations. Of these outfalls, 54A, 55A, 55B, 57, 58, 59, 60, 62, 63, 64A, 64B, 64C, and 66A, are protected by flap gates. Outfalls 55, 56, 65, and 66 serve only upland areas but have bolt down castings on manholes within downstream flood prone areas. Outfall 56A is controlled by a manual valve and is only used as a relief for a nearby water tank.

Reach E2 does not have storm water pump stations; however, it does have a 54-inch relief sewer (Outfall 49A) that discharges downstream of the 4th Street Dam where the flood profiles drops. Outfalls 49B and 49C have flap gates and are connected directly the 54-inch relief sewer. Outfalls 53 and 53A discharge to the river until their flap gates close. At this point they overflow to the 54" relief sewer that discharges downstream of the 4th Street dam. Outfall 49 serves only on two catch basins, discharges directly to the Grand River and has a flap gate on the floodwall. The outfalls 48, 53C, 54, and 54A serve only upland areas but have bolt down castings on manholes that are within downstream flood prone areas. Outfall 54A also has a flap gate mounted to the Leonard Street bridge abutment. The Reach E2 storm water collection system has capacity to discharge the 1-year, 24-hour rain event to the Grand River at the BFE without causing localized flood greater than 1 foot in depth.

Reach E3 does not have storm water pump station. Outfalls 23, 29, 31, 32A, 33, 34, 35, 36, 37, and 38 discharge directly to the Grand River and have flap gates mounted either on the existing floodwall or in upstream manholes. Outfalls 21A, 21B, 21C, 22A, 29A, and 31A serve only upland areas but have bolt down castings on manholes

within downstream flood prone areas. Outfall 22 has a sluice gate that has been permanently closed. The Reach E3 storm water collection system has capacity to discharge the 1-year, 24-hour rain event to the Grand River at the BFE without causing localized flood greater than 1 foot in depth.

Reach E4, which includes the Market Avenue Storm Water Pump Station that discharges at Outfall 7C, has outfalls that serve small localize areas that drain directly to the Grand River and not to the pump station. Of these outfalls, 11, 12A, 12B, 15, 16, and 20A have flap gates mounted either on the existing floodwall or in upstream manholes. The inlets for outfalls 6, 7A, 7B, 13, 14, 18A, 19, 21A, 21B, and 21C serve only upland areas but have bolt down castings on manholes within downstream flood prone areas.

Reach E5, which includes the ring levee around the WRRF, does not have a pump station solely dedicated to storm water; however, screw pumps within the facility can be used in conjunction with outfall 3B to drain storm water and treated wastewater that is trapped inside the levee during a high-water event on the Grand River. Both outfalls 3A and 3B have sluice gates to prevent backflow into the WRRF. Outfalls 3C, 3D, 3E and 3F drain into the WRRF from the south. Each of these four outfalls has a gate valve that is closed during high water events. The outfalls 4 and 5 serve only small upland areas. Neither require bolt down castings on manholes.

Reach W1, which includes area north of Mill Creek, includes storm water drainage from both Grand Rapids and the City of Walker. The area is serviced by the Mill Creek Storm Water Pump Station that discharges to the Grand River through outfalls 137A and 137B. Outfalls 135A, 135B1, 135C1, 135C2, 135C3, 135C4, 135F and 136A have flap gates and are served by the pump station. Outfalls 135B, 135C, 135D, 135E are culverts under US-131 that are completely within the floodplain. They require no protection. Outfalls 133B, 134, 134A, and 135 along the Grand River and 136C and 139 along Indian Mill Creek serve only upland areas and are not within the official Reach W1 limits.

Reach W2, which includes areas south of Indian Mill Creek and north of I-196, is served by the Front-Scribner Storm Water Pump Station (Outfall 107B). Outfalls 109, 112, 117, 118, 119, 120, 121, 122 and 138 discharge directly to the Grand River and have flap gates. If the flap gates close flow is diverted to Outfall 107B. Outfalls 124, 125, 127A, 128, 131, 132, 133, and 133A discharge directly to the Grand River and have flap gates. These outfalls do not directly overflow to Outfall 107B when the flap gates close. However, flooding would be less than 1 foot of deep should the 1-year, 24-hour rainfall event occur when the river is at the BFE. Outfall 109D has no flap gate but is manually plugged by the City during flood events (see GRFPS Emergency Action Plan, Table 4). Outfall 109C is manually plugged by the 678 Front building owner. Outfall 108 is completely within the floodplain and does not require protection. Outfalls 109A, 109B, 110A and 111 serve only roof drains and discharge directly to the Grand River. Outfalls 113 and 123 drain only upstream areas (US-131) but have bolt down castings on manholes in downstream flood prone areas.

Reach W3 does not have a storm water pump station. All storm water drainage flows discharge at outfalls on the Grand River. Outfalls 96 and 103 have headwall mounted flap gates. When the flap gates close flow is diverted to the Wealthy Street Storm Water Pump Station via overflow pipes. Outfalls 105A, 105B, 105C, 107, and 107A have inlets above the BFE and do not required bolt down castings on downstream manholes. Outfalls 97, 99, 99A, 100, 102, 104 and 105 have inlets within the floodplain and require no protection.

Reach W4, which includes the Wealthy Storm Water Pump Station (Outfall 72G), has small localized areas that drain directly to the Grand River and not directly to the pump station. Outfalls 72, 72A, 72B, 72C, 72E, 72F, 72H, 72I, 72J, 83, 83A, 83B, 83D, 84, and 86. All of these outfalls are protected by flap gates except for Outfall 72A that has a manually operated sluice gate, Outfall 72H that is protected by a duckbill valve, and Outfall 83D that is manually plugged (see GRFPS Emergency Action Plan, Table 4). Outfalls 81A, 83C, 86A, and 87 serve upland areas and do not required bolt down castings on downstream manholes.

Joint Probability of Flooding

Joint probability of flooding for flood protection systems refers to the chance that interior (landward) flooding occurs while exterior (Grand River) flooding impedes the interior drainage system. The factors included in these analyses are time to peak discharge (interior and exterior), duration of flood gate closure, and the probability of an interior precipitation event.

Hydrologic Analysis

The volume of storm water runoff flowing to the pump stations was estimated using the methodology presented in Natural Resources Conservation Service (NRCS) *Technical Release 55, Urban Hydrology for Small Watersheds* as presented in the *WinTR-55* program (NRCS, 2009). The areas that drain to the individual pump stations were determined using topographic mapping provided by the Kent County Bureau of Equalization and storm sewer maps provided by the City Department of Environmental Services. The runoff curve numbers were developed using land uses determined from an evaluation of aerial photography available from the Kent County. Soil types used in the development of runoff curve numbers was determined using the NRCS Web Soil Survey (WSS) information for Kent County, Michigan, available on the internet.

Because of the size and complexity of the drainage system for each pump station, the time of concentration for each watershed was determined based on the topographic information provided by Kent County and the following time of concentration equation developed by the Federal Aviation Administration:

$$t_c = \frac{1.8(1.1 - C)L^{0.50}}{S^{0.333}}$$

where t_c = time of concentration (minutes)

C = average runoff coefficient

L = flow length (feet)

S = average slope

To simplify the calculations, it was assumed that all the storm water runoff would flow unimpeded to the pump stations. Table 3 summarizes the areas within the GRFPS that drain to each pump station, the runoff curve numbers, and times of concentration used in the TR-55 analysis. Because the time of concentration for the Wealthy Street Pump Station exceeded 10 hours, the peak storm water runoff was determined using the USACE HEC-HMS Hydrologic Modeling System program. Appendix 1 contains the full output listing from the WinTR-55 and HEC-HMS programs. The hydrologic analysis evaluated the storm water runoff resulting from the 1-, 2-, 5-, 10-, 25-, 50-, and 100-year return interval, 24-hour duration storms included in the data sets pre-programmed into the WinTR-55 and HEC-HMS programs. The rainfall was temporally distributed using the NRCS Type II rainfall distribution and the watersheds were assumed to have an average antecedent runoff condition. Table 4 summarizes the total precipitation and peak rainfall runoff for each storm.

Table 3
Watershed Characteristics
Grand Rapids Flood Protection System Interior Area

100	6.15	52	30	87	1198	567	198

The watershed area of the Grand River upstream of the U.S. Geological Survey (USGS) stream gage station no. 04119000 “Grand River at Grand Rapids, Michigan” is 4,900 square miles. The six pump station watersheds in Grand Rapids are relatively small in comparison to the overall Grand River Watershed upstream of Grand Rapids as shown in Table 3. The small pump station watersheds will react to rainfall events much more quickly than the Grand River Watershed. Figure 20 shows the 1 percent annual chance, 24-hour duration, precipitation runoff hydrographs for the pump station watersheds in Grand Rapids developed using the NRCS WinTR-55 and HEC-HMS programs. Note that all the watershed hydrographs peak in less than 9 hours and the runoff completely diminishes to 0 within 25 hours of the start of the rainfall.

The 1 percent annual chance flood in the Grand River was developed from historic records for the top ten largest floods on the Grand River at Grand Rapids using data collected at the USGS stream station no. 04119000. To determine the shape of the 1 percent annual chance flood hydrograph, the hydrographs from the top ten discharge magnitude floods in Grand Rapids were aligned so that their peaks coincided as shown in Figure 21.

From these aligned hydrographs, the 1 percent annual chance flood hydrograph was estimated assuming a peak discharge of 50,000 cubic feet per second (cfs), which is the peak discharge used in the effective HEC-RAS hydraulic model of the Grand River. The final 1 percent annual chance flood hydrograph is shown in Figure 22. Note that the time to peak for the Figure 22 hydrograph is 625 hours, which is much greater than the time to peak for the interior pump station watersheds.

Because the relative size of the interior (inside the GRFPS) and exterior (Grand River) drainage areas are drastically different, the probability of interior and exterior events was assumed be independent. This is consistent with assumptions used in the coincident frequency methods published in USACE Engineering and Design Manual *EM 1110-2-1413 Hydrologic Analysis of Interior Areas*. These methods are applicable where interior and exterior events are independent and occurring where small interior drainage areas are near large rivers.

High Water Operations and Duration

When the Grand River floods in Grand Rapids, water levels will reach elevations where the flap gates or interior weir elevations (Market Avenue Pump Station) at each pump station will close and the pump stations will be activated. Table 5 shows the closing elevation for each pump station's bypass conduit flap gates (or overflow weir) assuming the flap gates close when the Grand River elevation reaches the top of flap gate elevation, the river discharge necessary to reach the top of flap gate elevation, and the duration that the pump station will be activated based on the 1 percent annual chance flood hydrograph for the Grand River (Figure 22). The duration of pump station operation was determined by overlaying the flap gate closure (Market Avenue Pump Station weir crest) discharges on the 1 percent annual chance flood hydrograph as shown in Figure 23. The discharges necessary to close the flap gates or overtop the Market Avenue Pump Station weir elevation were obtained through multiple runs of the HEC-RAS model of the Grand River with different flood discharges.

Table 5
1 Percent Annual Chance Flood
Pump Station Bypass Conduit Flap Gate Operation

Pump Station	Grand River Discharge When Flap Gate Closes (cfs)	Pump Station Bypass Conduit Flap Gate Closure and Opening Elevation Feet, NAVD88*	Duration (Hours)
Wealthy Street	7,900	593.34 (594.34)	903
Market Avenue**	11,730	596.00 (597.02)	619
Front/Scribner	17,450	601.27 (599.99)	303
Caledonia Street	17,220	609.36 (599.88)	307
Palmer Street	11,530	608.28 (596.90)	631
Indian Mill Creek	17,000	609.67 (599.78)	310

*Elevations in parentheses are the corresponding flood elevations at USGS station no. 04119000.
**River water level exceeds height of diversion weir causing slide gate internal to pump station to close and water to flow into wet well. There are no outlet flap gates.

Joint Probability Analysis

Average daily river discharges for the years 1901 through 2012 were obtained for USGS station no. 04119000 Grand River at Grand Rapids, Michigan from the USGS Michigan Water Science Center internet web site. Additionally, a stage versus discharge rating curve was obtained for the gage from the USGS. The USGS gage rating curve had a maximum river stage of 20 feet at a discharge of 30,200 cfs. The gage depth was then converted to a river stage by adding the gage datum of 585.7 feet NGVD29 resulting in an elevation vs. discharge rating curve. For river discharges above 30,200 cfs, computed river elevations at the USGS gage location were obtained from the HEC-RAS (USACE, 2010) water surface profile model of the Grand River approved by FEMA in 2015 for a planned update to the current effective Federal Emergency Management Agency (FEMA) Flood Insurance Study (FIS) of Grand Rapids (FEMA, 1982). The resulting elevation vs. discharge rating curve spanned the entire range of Grand River discharges.

The Grand River gage discharge data was ordered from the highest recorded average daily discharge in March 1904 (53,300 cfs) to the lowest recorded average daily discharge in August 1936 (381 cfs). The frequency of occurrence for each discharge value was calculated, which is shown in Figure 24. The discharges were then related back to the elevation vs. discharge rating curve and the frequency of occurrence for each river elevation was then established. Figure 25 shows the resulting Grand River elevation versus percent time exceeded at the USGS gage in Grand Rapids.

Probability is defined as the likelihood that a given event will occur, and it is expressed as a decimal number less than or equal to 1.0. The data used to generate Figure 7 was divided into discharge ranges, and the exterior (Grand River) percent exceedances and probabilities for each range summarized in Table 6. The sum of all probabilities is equal to 1.0 (100 percent), which covers all observed discharges for the period of record evaluated. The probabilities in Table 6 were used to evaluate the chance of exterior conditions meeting a range of discharges and river elevations.

Table 6
Average Annual Exterior Percent Exceedance and Probability
Grand River at Grand Rapids, Michigan

Discharge Range (cfs)	No. of Occurrences	Average Annual Exceedance (Percent)	Average Annual Probability
0 – 1,000	1,262	98.55	3.99E-02
1,001 – 2,000	9,730	80.33	3.08E-01
2,001 – 3,000	6,548	53.70	2.07E-01
3,001 – 4,000	3,938	37.79	1.25E-01
4,001 – 5,000	2,798	27.34	8.86E-02
5,001 – 6,000	2,006	19.79	6.35E-02
6,001 – 7,500	1,897	13.52	6.00E-02
7,500 – 9,000	1,103	8.96	3.49E-02
9,001 – 11,000	912	6.32	2.89E-02
11,001 – 13,000	486	3.58	1.54E-02
13,001 – 15,000	315	2.31	9.97E-03
15,001 – 17,000	219	1.49	6.93E-03
17,001 – 20,000	177	0.88	5.60E-03
20,001 – 25,000	129	0.42	4.08E-03
25,001 – 35,000	56	0.13	1.77E-03
35,001 – 45,000	10	0.04	3.17E-04
45,001 – 50,000	5	0.0119	1.58E-04
50,001 – 53,300	2	0.0016	6.33E-05
Total	31,593	---	1.00

Data for the interior discharges were not available for any of the pump station outlets or storm sewer outfalls. Therefore, probabilities were assigned directly from recurrence intervals of interior precipitation as discussed in EM 1110-2-1413.

For the GRFPS, the joint probability analysis was based on two independent events occurring separately. This means that the probability of event A (interior rainfall runoff) is not dependent on the occurrence of event B (pump station operation). For Grand Rapids, a small drainage area (interior) is located adjacent to a large river drainage basin (exterior). If the following definitions are used:

P (A) = Probability of event A

P (B) = Probability of event B

P (A | B) = Probability of event A given event B

P (B | A) = Probability of event B given event A

P (A ∩ B) = Probability of the intersection of event A and event B

Then two events are independent if:

$$P (A \mid B) = P (A)$$

or

$$P (B \mid A) = P (B)$$

Applying the probability of the intersection of two events and substituting for independent events, the resultant is:

$$P (A \cap B) = P (A) \bullet P (B \mid A) = P (A) \bullet P (B)$$

$$P (B \cap A) = P (B) \bullet P (A \mid B) = P (B) \bullet P (A)$$

Therefore, the joint probability of independent events for interior and exterior flood events is:

$$P (\text{Interior} \cap \text{Exterior}) = P (\text{Interior}) \bullet P (\text{Exterior})$$

Tables 7 through 13 provide the tabular computations of the joint probability of interior rainfall runoff and exterior flood events sufficient to start pump station operations for each of the six storm water pump stations in Grand Rapids. The highlighted water surface elevation ranges in each table correspond to the flap gate closure (initiation of pump station operation) elevations listed in Table 5 and the joint probability of that river elevation with the probability of a 1 percent annual frequency of occurrence rain event.

Interior Flooding

The City of Grand Rapids Code of Ordinances, Title II – Utilities and Services, Chapter 32 – Stormwater Drainage System, Article 4 – Stormwater Management Standards, Section 2.245 – Stormwater Drainage System Design Criteria specifies that during normal river elevations storm drain pipes in collector systems are to be designed to handle a 10-year design storm while trunk systems are to handle the 25 to 100-year storm.

The City of Walker relies on the Kent County, Michigan *Development Drainage Rules*, for its storm water drainage system, which specify:

- Culverts are to be designed for a minimum 10-year storm in the developed watershed.
- Storm sewers are to be designed to have a 10-year storm flow capacity if a floodway is available.
- Storm sewers are to be designed to have a 100-year flow capacity if no floodway channel is available.

The floodway in this case is an overland conveyance to serve all trapped yard basins and low areas in the road to prevent flooding should the storm sewer fail or be inadequate to handle runoff from a severe storm.

High intensity rain events in watersheds tributary to the GRFPS in the City and in the City of Walker have caused minor street flooding as the amount of water exceeds the inlet and pipe capacity of the storm drainage system. However, because of the moderately steep topography of the Cities of Grand Rapids and Walker, which slopes toward the floodplain along the Grand River, the depth of street flooding does not exceed 1-foot as the excess storm water flows on the streets downhill to the next catch basin inlets that can handle the flow. The City of Grand Rapids has not recorded any persistent flooding problems in the areas outside of the floodplain along the Grand River. The City of Walker recently acted to resolve flooding problems along Turner Avenue (see Reach W1 below). Both the City of Walker and the City of Grand Rapids have evaluated the potential for storm water ponding and have confirmed that all low areas within the protected areas have positive drainage through storm sewers either directly to the river or to the storm water pump stations. If storm water outfalls at the Grand River were blocked due to high water, low area flooding would spill over into areas with storm sewers that lead to the storm water pump stations without resulting in flooding more than an average depth of 1-foot. The topography of the area behind the flood protection project does not support interior flooding to an average depth greater than 1 foot as confirmed by the topographic mapping provided with these levee certification documents. Areas of shallow flooding for each reach are identified as follows:

Reach E1 Both the Palmer Street Pump Station and the Caledonia Street Pump Station in Reach E1 were designed to handle the discharge from a 10-year, 24-hour duration storm. A small area of the watershed draining Reach E1 does not flow to the pump stations when the Grand River is at the BFE. However, water will continue to discharge through partially open flap gates with as little as 6-inches of hydraulic head. Therefore, there has been little flooding in the areas adjacent to the GRFPS in Reach E1.

Reach E2 There are no storm water pump stations in Reach E2; therefore, all storm water drainage is directed directly to the Grand River. Street flooding in the floodplain areas adjacent to the GRFPS in Reach E2 is not usually a problem, rainfall from a 1-year event in conjunction with Grand River levels sufficient to close the backflow prevention devices on the storm drainage outfalls could result in shallow (<1 foot) street flooding at the following location:

- Monroe Avenue from I-196 to Mason Street and 6th Street from Monroe to Bond Avenues.

Reach E3 In Reach E3 there is no pump station to handle discharge to the Grand River in the event flood levels cause closure of backflow prevention flap gates. There has been little flooding in the areas adjacent to and interior to the GRFPS in Reach E3; rainfall from a 1-year event in conjunction with Grand River levels sufficient to close the backflow prevention devices on the storm drainage outfalls could result in shallow (<1 foot) street flooding at the following locations:

- Intersection of Market Avenue and Fulton Street.
- Portions of Monroe/Market Avenues north and south of Fulton Street.
- Campau Avenue between the walkway leading to the Blue Pedestrian Bridge and Pearl Street.

Reach E4 The Market Avenue Storm Water Pump Station is in Reach E4, and it was designed to handle the discharge from a 10-year, 24-hour duration storm. The storm water drainage in the watershed that drains to Reach E4 is handled by the pump station with no interior ponding areas caused by excessive rainfall events.

Reach E5 Reach E5 includes the area encircled by the ring levee around the WRRF. Under long-duration intense rainfall events in conjunction with flood events on the Grand River when the flap gates and sluice gate on the storm water outfalls are closed, the screw pumps used to discharge treated wastewater at the head of outfall 3B can be used to discharge storm water that ponds inside the ring levee. In addition, water will pond at the northeast corner of the WRRF where it will be pumped over the levee into Plaster Creek using portable pumps. Interior ponding is kept below an average of 1-foot depth using the WRRF portable pumps and screw pumps.

Reach W1 The Indian Mill Creek Storm Water Pump Station is located along Indian Mill Creek in Reach W1. This pump station receives storm water drainage from both the City and the City of Walker. In Walker excess storm water that is blocked from flowing to the Grand River due to flap gate closure on the culverts beneath Turner Avenue is conveyed through a relief storm sewer to the Indian Mill Creek Storm Water Pump Station in Grand Rapids to handle discharge to the Grand River. However, water will continue to discharge through partially open flap gates with as little as 6-inches of hydraulic head. There has been little flooding in the areas adjacent to and interior to the GRFPS in Reach W1; however, the 1-year rainfall event could result in street and adjacent area flooding to a depth of less than 1 foot at the following location:

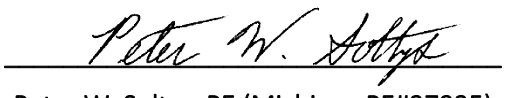
- Portions of Turner Avenue north of US-131 ramps to the PADNOS Leitelt, Inc. facility at 2301 Turner Ave. NW.

Reach W2 The Front-Scribner Storm Water Pump Station is located along the Grand River in Reach W2. There has been little flooding in the areas adjacent to and interior to the GRFPS in Reach W2 and no ponding areas due to excessive rainfall have been identified.

Reach W3 are no storm water pump stations in Reach W3 although the Wealthy Street Storm Water Pump Station in Reach W4 also handles storm water from this reach. No ponding areas due to excessive rainfall have been identified in this reach.

Reach W4 The Wealthy Street Storm Water Pump Station is set back from the Grand River in Reach W4. During rainfall from a 1-year event in conjunction with the Grand River at flood stage, an area that would be subject to interior flooding is in the immediate area of the pump station. The pump station has been flood-proofed in anticipation of this occurrence. No other ponding areas due to excessive rainfall have been identified in this reach.

Fishbeck attests that the modeling data, documentation, and the findings of no ponding areas with the average depth greater than one foot meet the requirements of this section of 44 CFR 65.10.



Peter W. Soltys, PE (Michigan PE#37935)

Historic High Water

Grand Rapids has experienced only one flood that exceeded the 1 percent annual chance flood discharge of 50,000 cfs at the USGS gage. This flood occurred in March 1904 before the current flood protection system was constructed. The most recent flood since the completion of the existing GRFPS occurred in April 2013 and had a peak discharge of 35,100 cfs. This flood had an annual chance of occurrence of between 4 percent and 10 percent. Interior area flooding during the April 2013 flood was largely located in low lying areas along the left (east) river bank in Riverside Park at the north end of the City.

Summary and Conclusions

The GRFPS protects approximately 1,420 acres on the right (west) bank and 195 acres on the left (east) bank of residential, commercial, institutional, and industrial properties within the City boundaries from a Base Flood (1 percent annual chance of occurrence) event. During a flood event, the bypass conduit flap gates may close at the Wealthy Street, Front/Scribner, Caledonia Street, Palmer Street, and Indian Mill Creek Pump Stations may close and the bypass weir at the Market Avenue Pump Station may overtop causing the pump stations to begin pumping, but the time to peak of the river (exterior) is much longer than the time to peak for the interior rainfall runoff event. Therefore, the interior area will drain prior to the arrival of the Grand River flood peak.

The joint probability analysis for a 1 percent annual chance event on both the interior and exterior was estimated to be a rare occurrence. The pump station backflow prevention devices (flap gates on the bypass conduits and a sluice gate in the Market Ave. Pump Station) would be closed at different exterior river elevations while an additional precipitation event occurs at a 100-year annual return interval (0.1 probability). The joint probability of interior and exterior flooding is summarized in Table 13.

Table 13
Joint Probability of 1 Percent Annual Frequency of Occurrence Interior Rainfall Event and Exterior Flooding Sufficient to Initiate Pump Station Operations

Pump Station	Joint Probability of Interior and Exterior Events*	Recurrence (Years)
Wealthy Street	3.49E-04	2,865
Market Avenue	1.54E-04	6,494
Front/Scribner	5.60E-05	17,857
Caledonia	5.60E-05	17,857
Palmer	1.54E-04	6,494
Indian Mill Creek	6.93E-05	14,300

*Pump station operation was assumed to occur at the flap gate closure/weir overtopping elevations given in Table 5. These elevations were used in Tables 7 through 12 to obtain the joint probabilities.

As shown in Table 13, the existing GRFPS project provides a very low probability of interior flooding during flooding in the Grand River in the drainage areas served by the stormwater pump stations. All depressions where storm water accumulates have direct storm sewer connections to the river or to the storm sewers served by the storm water pump stations. The potential for interior flooding while the Grand River is at flood stage was evaluated, and it was determined that water will not pond to an average depth greater than 1-foot in the areas protected by the GRFPS. In areas not served directly by the pump stations, the water that collects in depressions and on streets in the areas protected by the GRFPS will either overflow into adjacent drainage areas served by a stormwater pump station or directly into the Grand River before the average depth of ponding exceeds 1 foot.

USGS	U.S. Geological Survey

Statement of Purpose

The purpose of this Emergency Action Plan (EAP) is to minimize the hazard to life and property during a flood emergency event in the City of Grand Rapids, Michigan (City). The functionality of the City's response to any emergency situation is dictated by the National Incident Management System (NIMS) with an Incident Commander (City Manager) responsible for weighing the responsibility for each City department. This EAP is a subpart of this command structure. This EAP is specific to a flood emergency and should be coordinated with the overall emergency response provisions of the City's Emergency Action Guidelines.

The City, which encompasses an area approximately bordered by the City of Walker and Plainfield Charter and Grand Rapids Charter Townships to the east; and the Cities of Wyoming and Kentwood to the south, could be flooded to varying degrees depending on the water level in the Grand River and the nature of an unusual or emergency event. Should the City experience an emergency event that exceeds the GRFPS level of protection, portions of the protected area could be inundated by flood waters. In addition to residential structures (including their contents) and public infrastructure (roadways, railroads, and utilities), schools, industrial facilities, and commercial establishments could be damaged.

Communication of the emergency situation will be on cellular telephones with the Kent County 800 MHz Radio System as a backup. All City, County, and State officials will observe rules of jurisdiction and proper chains of command.

City departments are responsible for monitoring the situation during major floods, when a potentially hazardous condition is developing, and when levee and/or floodwall failure is imminent or has occurred. City departments will respond in accordance with this document. Refer to the Emergency Notification Chart Figures 1 and 2. It is the responsibility of every EAP participant to be fully aware of his/her duties and to execute those duties to the best of their ability.

System Description

The Grand River Flood Protection System (GRFPS) consists of a combination of four types of protective structures built along the banks of the Grand River. These protective structures may be generally classified as: 1) concrete flood walls; 2) low earth levees/embankments constructed atop natural stream banks; 3) highway embankments; 4) railroad embankments; and 5) bridge abutments. The interior flood control system consists of six pump stations, the stormwater collection system, and a series of floodwall backflow devices that drain to the Grand River. Under non-flood conditions in the Grand River, stormwater discharges directly to the river through pipe penetrations through the floodwalls and storm drains installed in the natural stream banks. In the event that flood stages in the river are high enough to close the backflow devices on the stormwater drain outlets, the stormwater flow is diverted to the permanent pump stations and portable pump systems.

The GRFPS was designed to protect approximately 1,420 acres on the right (west) bank and 195 acres on the left (east) bank of residential, commercial, institutional, and industrial properties within the City boundaries from the 100-year flood. The project also provides pumping capacities, stormwater interceptors, and gravity outfalls to discharge interior runoff during a rainfall event. A brief description of each flood protection component is provided in Tables 1, 2, and 3 and the location of each component is shown in Figure 3.

Table 1
Grand River Flood Protection System
Eastside Riverbank

Component (Downstream to Upstream)	Length Referenced to River Centerline* (feet)	Location/Description
Levee	2,041	Protective levee around Wastewater Treatment Plant. Length shown is along river. Total ring levee length equals 7,425’
Embankment	2,100	Earth and urban fill along I-196 extending behind CSX Railyard, across Marquette Park and along Plaster Creek
Embankment	1,750	Earth and urban fill along top of stream bank from Plaster Creek to the Market Avenue Retention Basin
Concrete Floodwall	3,420	Market Avenue Retention Basin to downstream face of Wealthy Street Bridge abutment
Concrete Bridge Abutment	75	Wealthy Street Bridge abutment
Embankment	375	Urban fill along top of stream bank from the upstream face of Wealthy Street Bridge abutment to a distance 370’ upstream
Embankment & Sheet Pile	120	370’ upstream of Wealthy Street Bridge to CSX railroad bridge – steel sheet pile installed through urban fill capped by riprap
Concrete Bridge Abutment	35	CSX railroad bridge abutment
Embankment & Sheet Pile	85	CSX railroad bridge to 100’ upstream – steel sheet pile installed through urban fill capped by riprap
Concrete Floodwall	680	100’ upstream of CSX railroad bridge to City Yard
Embankment	740	Urban fill along top of stream bank from the City Yard to the downstream face of the U.S. Route 131 Bridge abutment
Concrete Bridge Abutment	320	U.S. Route 131 Bridge abutment

Table 1
Grand River Flood Protection System
Eastside Riverbank

Component (Downstream to Upstream)	Length Referenced to River Centerline* (feet)	Location/Description
Embankment	440	Urban fill along top of bank from the upstream face of the U.S. Route 131 Bridge abutment to parking lot downstream of Fulton Street
Concrete Retaining Wall with Embankment	100	Parking lot downstream of Fulton Street to the downstream face of the Fulton Street Bridge abutment. The embankment consists of low-height urban fill placed atop a concrete retaining wall
Concrete Bridge Abutment	90	Fulton Street Bridge abutment
Concrete Retaining Wall with Embankment	30	Upstream face of Fulton Street Bridge abutment to a point 30' upstream. The embankment consists of urban fill placed atop a concrete retaining wall
Embankment	160	30' upstream of the Fulton Street Bridge to a point 190' upstream of the Fulton Street Bridge. Urban fill embankment faced with grouted and loose concrete pieces; lawn and sidewalk above
Concrete Retaining Wall with Embankment	50	190' upstream of the Fulton Street Bridge to the concrete water sculpture wall. The embankment consists of urban fill placed atop a concrete retaining wall
Concrete Retaining Wall with Embankment	130	Urban fill placed atop a concrete water sculpture wall
Concrete Bridge Abutment	50	Concrete floodwall under Blue Bridge and along Riverwalk
Concrete and Brick Building Wall - including windows	300	Buildings are part of Riverfront Plaza complex and the windows are below the Base Flood Elevation
Concrete Floodwall	220	Concrete floodwall and foundation for the J.W. Marriott Hotel
Stone Masonry and Concrete Wall	115	Retaining wall and building foundation wall consisting of a structurally stitched and grouted natural stone wall capped with a concrete wall (brick building at 250-252 Pearl Street)
Concrete Bridge Abutment	65	Pearl Street Bridge abutment
Stone Masonry and Concrete Wall	90	Retaining wall and building foundation wall consisting of a natural stone wall capped with a concrete wall (part of Amway Grand Plaza Hotel)
Concrete Floodwall	100	Floodwall and concrete building foundation wall for the Amway Grand Plaza Hotel
Concrete Floodwall	95	Concrete amphitheater built into floodwall at the west end of Lyon Street
Concrete Floodwall	40	Wall extends from the concrete amphitheater at the west end of Lyon Street to the downstream end of the pedestrian bridge abutment just upstream of Lyon Street
Concrete Bridge Abutment	35	Gillette Pedestrian Bridge abutment just upstream of Lyon Street

Table 1
Grand River Flood Protection System
Eastside Riverbank

Component (Downstream to Upstream)	Length Referenced to River Centerline* (feet)	Location/Description
Concrete Floodwall	995	Upstream end of the Gillette Pedestrian Bridge abutment to the downstream end of the Bridge Street Bridge abutment
Concrete Bridge Abutment	110	Bridge Street Bridge abutment
Concrete Floodwall	40	Upstream end of the Bridge Street Bridge abutment to a point 40' upstream of the bridge. The concrete floodwall is also the foundation wall for the U.S. Post Office
Steel Sheet Pile and Concrete Floodwall	500	40' upstream of the Bridge Street Bridge to the downstream edge of the embankment for I-196. The concrete wall sits atop the steel sheet pile wall and is the foundation for the U.S. Post Office
Steel Sheet Pile and Concrete Floodwall	55	Downstream end of I-196 embankment to eastbound bridge pier. Steel sheet pile retaining wall at waterline with concrete and/or modular block retaining walls on slope
Concrete Retaining Wall & Bridge Pier	60	Bridge pier for eastbound I-196 acts as retaining wall. A low height concrete retaining wall is located at waterline
Concrete Retaining Walls	15	Concrete retaining wall on slope between eastbound and westbound I-196 bridges. A low height concrete retaining wall is located at waterline
Concrete Retaining Wall & Bridge Pier	70	Bridge pier for westbound I-196 acts as retaining wall. A low height concrete retaining wall is located at waterline
Concrete Retaining Walls	240	Concrete retaining wall on slope upstream of westbound I-196 bridge. A low height concrete retaining wall is located at waterline
Concrete Retaining Wall, Modular Block Retaining Wall & Embankment	475	240' upstream of I-196 to the 6th Street Dam. Concrete retaining wall at waterline with combinations of urban fill embankments, modular block walls and concrete retaining walls
Concrete Retaining Wall & Embankment	725	6th Street Park from the dam to the downstream edge of the 6th Street Bridge abutment. Concrete retaining wall at river's edge with clay levee built on natural ground above concrete wall
Stone Masonry Bridge Abutment	75	6th Street Bridge abutment
Concrete Retaining Wall, Modular Block Retaining Wall & Embankment	2,020	Upstream edge of 6th Street Bridge abutment to upstream end of Canal Park. Concrete retaining wall at river's edge with natural ground and intermittent modular block retaining walls
Concrete Retaining Wall & Embankment	950	Upstream end of Canal Park to just upstream of Leonard Street Bridge. Concrete retaining wall at river's edge with natural ground sloping up from wall to former railroad bed
Urban Fill and RR Embankment	1,510	Just upstream of the Leonard Street Bridge to the Water Department Yard. Railroad embankment constructed above urban fill. 670' section of earth embankment placed atop railroad embankment

Table 1
Grand River Flood Protection System
Eastside Riverbank

Component (Downstream to Upstream)	Length Referenced to River Centerline* (feet)	Location/Description
Concrete Retaining Wall & Embankment	280	Water Department Yard. Concrete retaining wall at river's edge with railroad embankment constructed above on urban fill
Urban Fill and RR Embankment	920	Water Department Yard to the downstream edge of the CSX Railroad Bridge. Railroad embankment constructed above urban fill
Concrete Bridge Abutment & Embankment	30	CSX Railroad Bridge abutment. Urban fill embankment at abutment
Urban Fill and RR Embankment	870	Upstream edge of CSX Railroad Bridge abutment to Palmer Street Pump Station. Railroad embankment constructed above urban fill
Embankment	250	Palmer Street Pump Station to downstream edge of the Ann Street Bridge abutment. Urban fill embankment
Concrete Bridge Abutment	100	Ann Street Bridge abutment
Embankment	1,450	Upstream edge of Ann Street Bridge abutment to Knapp Street entrance to Comstock Riverside Park. Urban fill and earth embankments with pedestrian path on top
Embankment	120	Knapp Street to Parade Drive along Monroe Avenue. Earth embankment along west side of Monroe Avenue
Natural Topography & Embankment	2,300	Parade Drive to Guild Street. Short (50') earthen embankment between low spots in natural topography along west side of Monroe Avenue and raised entrance (60') to Comstock Riverside Park at Guild Street
Natural Topography & Embankment	2,200	Guild Street to Sligh Boulevard. Short earthen embankment between low spots in natural topography along west side of Monroe Avenue
Natural Topography	4,670	Sligh Boulevard to downstream edge of I-96 Bridge abutment. Natural topography
Concrete Bridge Abutment	180	I-96 (eastbound & westbound) Bridge abutment. Concrete bridge abutment and approach embankment connection to natural topography

Stormwater Pump Stations

Pump Station	Number of Pumps (Capacity in Gallons Per Minute)	Location
Market Avenue Pump Station	4 (10,770)	East side of river at 741 Market Avenue; downstream of the Oxford Street Trail Bridge
Wealthy Street Pump Station	10 (53,125)	West side of river downstream of the Oxford Street Trail Bridge; access from the south side of Wealthy Street just east of the Indiana Avenue intersection
Front & Scribner Pump Station	6 (53,125)	West side of river just upstream of the I-196 Bridge and to the east of Scribner Avenue; access from parking lot just south of intersection of Front Avenue and 4th Street at the Fish Ladder Park
Indian Mill Creek Pump Station	3 (4,500)	West side of river along Indian Mill Creek upstream of the confluence with the Grand River; at west end of parking lot on the south side of Ann Street for building at 400 Ann Street
Caledonia Street Pump Station	3 (4,500)	East side of river in Water System Department yard at 1430 Monroe Avenue; along river bank and adjacent to abandoned railroad grade
Palmer Street Pump Station	3 (4,500)	East side of river downstream of the Ann Street Bridge; along river and adjacent to abandoned railroad grade at back of former Baker Furniture factory

Emergency Detection Evaluation, and Classification

Definition of Terms

- *Warning*: The flood stage is 18-feet or above as measured at the U.S. Geological Survey (USGS) gage upstream of the Fulton Street Bridge ("Gauge 0" Datum: 585.25 NAVD88). Alternatively, the levee, floodwall, or drain pipe backflow prevention devices have failed or actual failure is in progress and immediate warnings to evacuate are required. A (Warning) condition is the primary focus of this EAP.
- *Watch*: The flood stage is 12-feet and predicted to continue rising ("Gauge 0" Datum: 585.25 NAVD88). Alternatively, a condition exists that could potentially develop into an unsafe condition, but the immediate safety of the levee and/or floodwall is not in jeopardy. The deficient condition should be monitored closely, and a licensed professional engineer familiar with levee and floodwall safety should be contacted to recommend remedial measures. Provisions for addressing deficient conditions are included in the Operations, Maintenance, and Inspection Manual.

Inspection

The levee, floodwall, embankment, and retaining walls should be inspected as required by the Operations, Maintenance, and Inspection Manual. The person(s) responsible for maintaining and/or inspecting the levee and floodwall should be familiar with this section.

High Water Levels

Grand Rapids is subject to rising water levels depending on climatic and meteorological factors. There is an automatic water level recorder operated by the USGS along the Grand River (USGS Station No. 04119000) to determine the current state of the water levels.

Several water levels have been established to trigger specific actions by the City:

- USGS gauge water level = 8.45-feet (elevation 593.70-feet NAVD88) and rising: Street Maintenance Department begins road closure installations
- USGS gauge water level = 12-feet (elevation 597.25-feet NAVD88) and rising: (Watch) Alert issued for City Departments
- USGS gauge water level = 18-feet (elevation 603.25-feet NAVD88) and rising: City Incident Commander (City Manager) issues (Warning) Alert and Kent County Emergency Management & Homeland Security begins to set up Command Center at the Kent County Sheriff's Office
- USGS gauge water level = 21-feet (elevation 606.25-feet NAVD88): Command Center at Kent County Sheriff's Office fully operational

Regular "walk-by" inspections as dictated by the City Engineer should occur daily when the Grand River is at a flood level sufficient to trigger the high water (Warning) Alert by the City Manager. Visual observations from inspections should be documented to establish current event baseline conditions, any developing conditions, or damage assessment.

Potential Levee and Floodwall Problems

Almost all levee and floodwall failures can be directly related to seepage, piping, sediment loss, slope failure, settlement, concrete joints, or problems related to conduits through the levee embankment and/or floodwall. Each of these potential levee and floodwall problems is discussed in the following paragraphs.

Seepage

Depending on the water depth and duration of a particular water depth in a stream, all levees normally experience a minor degree of seepage as water from the stream seeks paths of least resistance through the levee embankment and the levee and/or floodwall foundations. However, excessive seepage or seepage that is visually different than previously observed can be indicative of major problems within the levee embankment and the levee and/or floodwall foundations. Seepage must be controlled in both velocity and quantity. Along the GRFPS, seepage is most likely to occur at the following locations:

Eastside

- Levee surrounding the wastewater treatment plant
- Abandoned railroad embankment between Leonard and Knapp Streets

Westside

- Floodwall from Wealthy to Fulton Streets
- Levee in front of Gerald R. Ford Museum
- Floodwall from the fish ladder structure in Fish Ladder Park just upstream of I-196 to behind the main building at the Kent County Public Service Center south of the intersection of Scribner Avenue and Richmond Street
- Levee in the Kent County Public Service Center Yard extending from the end of the floodwall at this location

Indicators

- Appearance of wet spots or springs in the protected (dry) face of the earth embankment or in areas immediately adjacent to the toe of the embankment or floodwall
- Areas that prematurely thaw, or where snow melts prematurely during the winter
- Areas of wetland-type vegetation (reeds, cattails, etc.) along the protected (dry) side toe of the levee embankment or floodwall
- Boils, seepage, piping (fine-grained material being ejected in a stream of water out of a hole in the levee embankment forming a small cone of material), appearing on the protected (dry) face of the levee embankment or in the area adjacent to the protected (dry) side toe of the embankment and/or floodwall
- Sinkholes or depressions occurring on the levee embankment or in the area adjacent to the toe of the embankment slope or floodwall
- Landslides on the protected (dry) side face of the levee embankment. Note that shallow depth landslides are not always caused by seepage
- Depressions formed in either side of the levee embankment and the levee crest including in the riprap protection on the river side of the levee. Depressions could also form along the paths of the buried drain pipes through the levee embankments and floodwall
- The appearance of a persistent whirlpool (vortex) in the Grand River adjacent to the levee embankment or floodwall during a high water event

Reporting

Reporting and documentation of potential levee and floodwall problems should be completed in accordance with the inspection forms included in Appendix 2 of the Operations, Maintenance & Inspection (OM&I) Manual. Note that current river stage information can be obtained from the National Weather Service (NWS) Forecast Office, Grand Rapids, Michigan, Advanced Hydrologic Prediction Service at:

http://water.weather.gov/ahps2/hydrograph.php?wfo=grr&gage=gdrm4

or the USGS Michigan Water Science Center at:

http://waterdata.usgs.gov/mi/nwis/sw

Piping of foundation and/or embankment material is normally indicated by a buildup of materials around the seepage area or a slope failure (e.g. boils, slumps, landslides, sinkholes). Catching some seepage water in a clear glass jar and looking through the water can often indicate particles in suspension during the initial stages of piping. If the seepage velocity is high, the water may just be cloudy or muddy and buildup of materials may be some distance from the actual seepage location. After the seepage is reported, the area should be photographed before any measures are taken to control the problem. Disturbance of any seepage indicator, such as the buildup of sediment around the seepage area, should be kept to a minimum. Any occurrence of a persistent (not dissipating and/or moving downstream) whirlpool in the Grand River adjacent to the levee and/or floodwall is an emergency (Warning) condition.

Temporary Controls (until more permanent repairs can be made)

- Changes in Seepage, Boils, and Whirlpools
  - Observe for various stream levels to determine the approximate elevation that initiates seepage and the location of the seepage source.
  - If the source of the seepage can be found or a suspected location identified, place a blanket of impervious material such as bentonite clay over the seepage source.
  - If the seepage is persistent, install a grout curtain inside the levee embankment or along the river face of the floodwall.
- Boils
  - Place a ring of sandbags or a large diameter pipe around the boil area to pond water above the ground surface at the boil location and reduce the velocity of the water emanating from the boil.
  - Never dump sand or similar material into a boil until an assessment of the sediment in the boil can be completed.
  - After an assessment of the sediment associated with the seep or boil, an overlay of an approved granular material may be selected as a control measure.
- Sinkholes, Settlement, and Depressions
  - The cause of any sinkholes, settlement, and depressions should be investigated by a qualified geotechnical engineering firm.
  - After documenting the location of sinkholes, settlement, or depressions, they should be filled with earth or rocks until more permanent measures can be taken to resolve the problem.
  - The option exists to perform a temporary control as recommended by a licensed professional engineer with expertise with flood control and safety and approved by the City Engineer.

Slope Failure

In general, slope failures occur gradually, and if detected in the early stages, measures can be taken to prevent total embankment failure. On the river (wet) levee and embankment slopes, failures may occur shortly after a rapid decrease in the river level following a protracted flood. On the protected (dry) levee slope, failures may occur after large rainfall events following a protracted period of hot, dry weather where the levee soils shrink and crack, allowing water to penetrate the surface instead of normally infiltrating. Slope failures can also occur in multiple areas and at different times, but are more likely during special operating or loading conditions or during extended periods of heavy rainfall. They may be initiated by excessive vibrations, seepage, earthquakes, or erosion. Massive slides can initiate catastrophic failure of a levee.

Indicators

- Slumping, sloughing, or sliding of soil material on either the river (wet) face or protected (dry) face of the levee or embankment.
- Displacement of riprap along the river (wet) face of the levee or embankment.
- Cracks in the levee or embankment. Transverse cracks appear across the levee or embankment and might indicate differential settlement within the embankment. Such cracks provide avenues for seepage water and piping could quickly develop. Longitudinal cracks run parallel to the levee or embankment and may signal the early stages of a slide or slump on either face of the embankment.
- Erosion of the river (wet) side or protected (dry) side of the levee or embankment caused by a rapid decrease in the river level following a protracted flood, rainfall, runoff, snow melt, river currents, wave action, lack of vegetation, foot-traffic, overtopping, or increased seepage through the levee or its foundation. Deep erosion gullies and levee waterline erosion can threaten the structural integrity of the embankment. Erosion along the base of the levee indicates potential deterioration of the foundation that could result in landslides or misalignment of the embankment.

Reporting

Reporting and documentation of potential levee and floodwall problems should be completed in accordance with the inspection forms included in Appendix 2 of the OM&I Manual.

Temporary Controls (until more permanent repairs can be made)

- Slumps/Sloughs/Landslides/Erosion/Settlement
  - For slumps, sloughs, erosion, and settlement on the levee embankment, or at the toe of the embankment slope, fill the affected area with soil, rockfill, or sandbags until more permanent repairs can be made.
  - On the protected (dry) face of the levee embankment, cover the repaired area with plastic sheets or other erosion-resistant materials to prevent subsequent erosion during storms.
  - For landslides, stabilize the toe of the slide by weighting with soil, rock, or gravel. If necessary, fill materials should be placed at the top of the slide to restore freeboard after the toe is stabilized.
- Riprap Displacement
  - Temporarily repair displaced riprap by filling the affected area with additional riprap or sandbags until the cause of the displacement can be determined and more permanent repairs made.
  - Long-term repairs may include removing the riprap, re-grading the levee embankment slope, installing a permeable geotextile fabric filter, placing a layer of bedding gravel, and replacing the riprap stone.
- Cracks
  - Fill non-leaking cracks in the levee embankment with soil, rocks, cement grout, or sandbags until more permanent repairs can be made.
  - Improve (line) the drainage path from the crack to prevent further erosion.
  - A leaking crack is an emergency (Warning) situation. The crack should be filled immediately with an available material including bentonite clay, soil, hay bales, sandbags, and rocks to stop or slow the flow of water until the stream level recedes and a permanent repair is made.
- Levee Overtopping
  - If it is apparent that the floodwall segments of the GRFPS will be overtopped, this is an emergency (Warning) situation. The City Incident Commander and Kent County Emergency Management & Homeland Security Office should be notified to initiate evacuation procedures for the areas potentially affected by the coming flood.

Settlement

Settlement is the decrease in elevation of soil from its originally constructed elevation. To a certain degree, settlement of a levee embankment and floodwall foundation is normal and to be expected. Often settlement occurs because the soil was not fully compacted against a concrete structure or steel sheet pile wall. Settlement is most likely to occur along the levee crest, adjacent to pipe outfalls, adjacent to pump stations, and at the interface between the levee embankment or natural ground and the floodwalls. Settlement of the ground along the floodwall segments could indicate deterioration and seepage through the floodwall. Settlement of the ground may also result from gypsum voids in the underlying bedrock. Settlement along the path of drain pipes through the levee and floodwalls, which could be an indication that material is being removed within the levee or behind the floodwall along the pipe, is most likely and an emergency (Warning) situation.

Indicators

- A noticeable slump in the levee embankment crest.
- Depression in the ground along the path of the drainage pipes.
- Depression in the ground along the steel sheet pile floodwall.
- Depression at the interface between the levee embankment and the steel sheet pile floodwall.
- Settlement along the length of a portion of the concrete floodwall.

Reporting

Reporting and documentation of potential levee and floodwall problems should be completed in accordance with the inspection forms included in Appendix 2 of the OM&I Manual.

Temporary Controls (until more permanent repairs can be made)

- Sandbags
  - Install sandbags in accordance with the Operations, Maintenance and Inspection Manual.
- Areas where settlement has occurred that are not actively continuing to settle should be filled with clay-type soil to return the levee crest or face to the as-constructed elevation. The clay-type soil should be compacted to 95 percent or above of maximum dry density at 1 percentage point below to 3 percentage points above optimum moisture content based on the Standard Proctor Density Test (ASTM D 698-78).
- Settlement may constitute a (Warning) and the City Engineer should be notified.

Floodwall Misalignment

Floodwall misalignment is the horizontal displacement or movement toward the river or the land. The misalignment of the concrete floodwalls along the Grand River could indicate significant foundation soil movement towards the river, impact of a large or heavy floating object during a flood, ice jam impact or loading, and/or a significant superimposed load adjacent to the floodwall. This also includes loads associated with a receding river stage in which the groundwater on the land side is lagging the river levels.

Indicators

- Cracked concrete on either side of the floodwall
- Tilting or bowed sections of floodwall
- Visible gap and/or lack of waterstops at the joints in the floodwall
- A misalignment of the concrete surfaces at a joint or crack
- Sediment loss

Reporting

Reporting and documentation of potential levee and floodwall problems should be completed in accordance with the inspection forms included in Appendix 2 of the OM&I Manual.

Temporary Controls (until more permanent repairs can be made)

Misalignment of concrete monolith floodwalls is usually not a fast-moving problem and therefore should be considered a non-emergency (Watch) situation. If the wall is collapsing during a flood event, it is an emergency (Warning) situation. Any misalignment should be directed to the City Engineer and a strategic evaluation by a geotechnical and structural engineer for possible repair and realignment.

Backflow Device Problem

The flap gates and duckbill gates on the ends of the drainage pipes and pump station discharge lines through the levee and floodwall segments of the GRFPS are exposed to the flow in the Grand River and could be damaged or clogged by floating debris and ice impact. The flap gates in the structures adjacent to the pump stations can be jammed open by floating debris and ice.

Indicators

- Water flowing from storm sewer manholes and/or street stormwater inlets during high water conditions in the Grand River. This will typically be seen as water flowing down a street emanating from a manhole cover or catch basin; or ponding water at any location around a manhole cover or catch basin.
- Higher frequency of pump station operation

Reporting

Reporting and documentation of potential levee and floodwall problems should be completed in accordance with the inspection forms included in Appendix 2 of the OM&I Manual.

Temporary Controls

- Flap Gates in Gate Well Structures
  - Close the sluice gates in the gate wells until the water level subsides and the gate well is dewatered. Once the flap gates can be accessed, the debris and/or ice clogging the gate shall be removed and the flap gates returned to service.
- Drainage Pipes through Levee and Floodwall
  - If the flap gates are not operational, the inlet end of the pipe should be sealed using an inflatable plug or sandbags. Once the water level subsides in the Grand River, the flap gates should be unclogged, repaired, and/or replaced.

Additional Comments

The types of levee and floodwall failures described above are often interrelated in a complex manner. For example, uncontrolled seepage may weaken the soil and lead to a slope failure. A slope failure may shorten the seepage path and lead to a piping failure. Minor defects such as cracks in the levee embankment may be the first visual sign of a major problem that could lead to failure of the structure. A licensed professional engineer experienced in levee and floodwall design and construction should evaluate the seriousness of all deficiencies and recommend appropriate permanent remedial measures.

Whenever a potential emergency situation is reported, the City Engineer or his/her designee should immediately visit the area of concern at the GRFPS and evaluate the situation as described in the above paragraphs. If the situation is severe enough that there is any concern that there could be an uncontrolled release of water into the

area protected by the GRFPS, the City Engineer shall initiate a levee failure (Warning) alert in accordance with the Emergency Notification Chart in Figures 1 and 2.

If upon visiting the potential problem area at the GRFPS, the City Engineer or his/her designee determines that the situation can be handled without danger of an uncontrolled release of water into the area protected by the GRFPS, the necessary work should be coordinated by the City Engineer with the asset management plan inspections, updates, and improvements.

Once a levee and/or floodwall problem progresses to the point that the levee and/or floodwall is failing, evacuation in the flood inundation zone, (see Inundation Map in Figure 6), may be necessary if emergency actions do not appear to be adequate to prevent flooding in the protected area.

Emergency Action

Emergency Action by River Stage

As the Grand River rises in the City, various actions are required to protect areas of the City from inundation by flood waters. Table 4 provides a list of actions by river stage that need to be performed. Note that Table 4 should be reviewed annually to ensure that it is up to date and reflects any modification to the GRFPS.

Preparedness

Levee Owner

The City is responsible for levee and floodwall inspections as outlined in the GRFPS Operations and Maintenance Manual. The City is also responsible for detecting emergency conditions and depending on the observed conditions, he/she is responsible for deciding the appropriate action under the NIMS Incident Commander and the appropriate Emergency Notification Chart in Figures 1 and 2 and in cooperation with the Environmental Services Department, Public Services Department, Water Systems Department, Traffic Control Department, Parks, Recreation and Forestry Department, Police Department, and Fire Department.

If flood (Watch) non-emergency conditions are predicted based on local observations and consultation with the NWS in Grand Rapids, the City Engineer should contact the Environmental Services Department to prepare to monitor pump station operations along the Grand River. If the water level reaches the (Watch) non-emergency condition and is continuing to rise, or if notification from the City Incident Commander and/or Kent County Emergency Management & Homeland Security Office is received, the Environmental Services Department and Public Services Department shall install the temporary flood control measures as described in Table 4. Personnel from the City Engineer's Office, Environmental Services Department, and Public Services Department should inspect the levee and floodwall daily to ensure that no problems are occurring that would trigger an emergency response. In the case that problems are detected, the problem area should be continuously monitored until the flood subsides and remedial measures can be implemented. After the flood subsides, the City Engineer's office should conduct an inspection of the levee, floodwall, and drainage structures, to determine if any damage has occurred that requires repair.

During flooding of the Grand River, the curious public and news media can create a major obstacle to performance of necessary tasks; therefore, levee and floodwall access control measures should be taken. In conjunction with any evacuation of residents in the area protected by the GRFPS, it will be necessary to provide easy access for equipment, supplies, and personnel involved in the effort to affect repairs. The City Engineer, Environmental Services Department, and Public Works Department should work closely with the City Incident Commander and Police and Fire Departments to prevent unauthorized access to the GRFPS and to facilitate movement of necessary equipment, supplies, and personnel to the levee and floodwall.

Notification

In the event of a flood (Warning) emergency condition or problems with the GRFPS, it is the shared responsibility of the City Engineer and Utilities Director to notify the City Incident Commander and Kent County Emergency Management & Homeland Security Office and brief them on the situation. The Kent County Emergency Management & Homeland Security Office will prepare and deliver a message for public release based on the existing conditions and information provided by the City Engineer and City Incident Commander. Preparation of (Warning) emergency messages should begin as soon as their potential need is apparent so that they can be issued promptly upon declaration of a (Warning) emergency condition. When time is available for their preparation, the initial message should contain all pertinent information. However, in some cases a (Warning) emergency condition may be declared with little or no advance notice. The following sample messages provide models for the first announcement in such cases. Subsequent announcements should provide additional details.

Announcement of Levee Failure in Progress

Urgent, Urgent: The City has announced that a portion of the levee (and/or floodwall) along the Grand River (has failed/is in imminent danger of failure).

Attempts to stabilize the levee (and/or floodwall) are underway, but their success cannot be determined as of yet. Residents living in the following areas should evacuate to high ground immediately:

- Name of area (location and extent)
- Name of area (location and extent)
- Name of area (location and extent)

Additional information will be released as soon as possible.

Announcement of Flood Crest Above Flood Protection Level

Urgent, Urgent: The City has announced that the Grand River is expected to crest at elevation (insert elevation), which is (insert number of feet) above the top of the flood protection levees and floodwalls in the City.

Residents living in the following areas should evacuate to high ground immediately:

- Name of area (location and extent)
- Name of area (location and extent)
- Name of area (location and extent)

Additional information will be released as soon as possible.

The simplest functioning means of communications will be used to maintain communications with authorities and construction contractors retained to stabilize the levee and/or floodwall. Notification will normally be on the Kent County 800 MHz Radio System or by cellular telephones.

The NWS will also be a primary source through which emergency announcements are released to the news media.

National Weather Service (Grand Rapids, Michigan): 24-hour telephone number 616.949.0643

The following radio and television stations should be contacted if the NWS cannot be contacted. These stations are considered to have broadcast areas covering Grand Rapids.

Evacuations

The City Incident Commander, Kent County Emergency Management & Homeland Security Office, and Grand Rapids Police Department, are responsible for evacuation of the flood inundation area. The City Incident Commander and/or Kent County Emergency Management & Homeland Security Office will also contact the Kent County Sheriff and Michigan State Highway Patrol for area coordination, as needed. The City Engineer should not assume responsibility for evacuation but should coordinate with the appropriate officials.

Termination and Follow-Up

The City Engineer should monitor the emergency situation at the GRFPS and keep the City Incident Commander informed of developing conditions. The City Incident Commander and the Kent County Emergency Management & Homeland Security Office are responsible for terminating the (Watch) non-emergency condition or the (Warning) emergency condition for the area protected by the GRFPS.

Following the emergency situation, the City Engineer is responsible for performing a follow-up evaluation of this EAP with the participants involved in the emergency.

EAP Coordination

The City Engineer is responsible for the coordination of this EAP. The responsibility encompasses the following items:

- Revisions to the EAP.
- Coordination of EAP exercises in cooperation with the City Incident Commander and Kent County Emergency Management & Homeland Security Office.
- Establishment of EAP training seminars for the City Engineer's Office, Environmental Services Department, Public Services Department, Water Systems Department, and City Incident Commander.
- Serving as the EAP contact for emergencies (Warning) and non-emergencies (Watch) related to the GRFPS.

Access to the GRFPS

The primary route of access to the GRFPS is from Monroe Avenue, NW, and Market Avenue, SW, along the left (east) Grand River bank and Front Avenue, SW, and NW, and Scribner Avenue, NW, along the right (west) river bank. Although there are numerous bridge crossings along the project, access across bridges should be minimized due to the potential hazard to the bridges caused by the flood waters and any debris or ice in the flood flow.

Response During Periods of Adverse Weather

During periods of adverse weather, the City Engineer should be prepared to isolate and protect areas of potential levee and floodwall repair from rainfall, ice, and snow. This includes stockpiling repair materials, including sand bags, sand, plastic sheets, gravel, and clay soil, and having a list of available contractors, equipment, and equipment operators, including portable lighting, generators, heavy-duty electric cords, earth moving equipment (skid steers, backhoes, front end loaders, bulldozers, etc.)

Response During Periods of Darkness

For emergency situations that occur at night, the City Engineer, Environmental Services Department, and/or Public Services Department, shall provide lighting, either fixed or portable, for the GRFPS that is sufficient to illuminate the site. At least three or more portable generators, maintained in good working order, are to be provided for use in levee, floodwall, and/or drainage structure failure emergencies. The generators and associated electrical cords shall be capable of providing power to any emergency electrical equipment including emergency lighting and have an output capacity that meets or exceeds the power required by emergency equipment.

Alternate System of Communications

Cellular telephones are to be used as an alternate means of communications.

Emergency Supplies and Resources

For emergency use, the City Engineer, Environmental Services Department, the Public Services Department, and/or the Water Systems Department shall have the following materials and supplies available at their respective facilities with sufficient transport vehicles to ensure a timely response to an emergency situation:

- Flashlights to provide lighting where emergency lighting does not illuminate and for directing traffic
- Portable, petroleum-fueled generator(s)
- Extension cords (heavy duty) for use with the portable generators and emergency equipment including lights
- Fire extinguishers (preferably type ABC) for extinguishing any fire that may occur in the emergency equipment
- Portable electric floodlights
- Fill material to dump into any levee and/or floodwall breach and to fill sandbags
- Sandbags
- Backhoe, trackhoe, front end loader, and/or skid steer for hauling and placing fill material
- Four-wheel drive vehicle and dump truck for hauling fill material and equipment
- One or more portable pumps with flexible hoses to assist in pumping water from the pump station wet wells in the event that one or more pumps become disabled
- Plastic sheets for temporary crack repair and for protecting eroded areas on the levee embankment
- Rope to assist emergency personnel
- Personal flotation devices
- First aid kit
- Traffic control cones and/or barriers

A list of available City equipment for emergency operations is included in Appendix C.

Emergency Contractors and Suppliers

The City should have sufficient personnel, equipment, and materials to respond to emergencies at the GRFPS. In the event that additional personnel and equipment is required at the GRFPS site, the City Engineer shall procure the required services on an emergency basis. A list of emergency response contractors is provided in Appendix D.

Table 4
Action Item Chart

Item No.	Address/Item	Location of Item	Description of Item	Critical Elevation (when problem occurs)		Action Required	Materials Needed (during 100-year event)	Equipment Needed (to deliver and onsite)	Responsible Department
				USGS Flood Stage (at Blue Bridge) 100-year = 25.46	NAVD 88 (at Location of Item)				
1	Storm Water Valve MH castings in Berm at WRRF	**East Side** - WRRF	Two 24" and two 12" storm sewers enter the WWTP from the CSX property to the south. The CSX property is below the the BFE. There are valves on these sewers in the grass embankment between the asphalt drive and perimeter fence. If these valves are open during an extreme flood the WRRF is susceptible to flooding.	19.9	602.0	Close all four valves.	None	2" Square valve key	Environmental Services Department
2	East Side Interceptor	**East Side** - Along Eastside of Grand River from MARB to Pearl Street	When the river rises the East Side Interceptor may become bouyant. The pipe is 12' wide and 11.25' tall and is cast-in-place concrete. The invert elevation at the Market Avenue Pump Station is approximately 584.0. The normal water level in the pipe is approximately 24".	12.0	594.5	Keep water level in East Side Interceptor no lower than 15 feet below the Grand River.	None	None	Environmental Services Department
3	240 Front Avenue	**West Side** - Floodwall between Letellier and Emperor Streets	4" core in floodwall for driveway drainage	21.0	604.8	Install 4" inflatable sewer plug; or place 30 sandbags behind the floodwall to plug the hole.	• 4" inflatable sewer plug = 1 • Sandbags = 30	Small air compressor	Environmental Services Department
4	355 Market Avenue (Chesapeake & Ohio Railroad)	**East Side** - RR Bridge between Wealthy and Goodrich Streets	The top of railroad ballast is slightly below the BFE.	24.5	608.6	Construct 50' of sandbag berm across railroad property and connect to the permanent flood control walls. Coordinate with CSX Transportation.	• Sandbags = 1,500 • Sand = 14 cyd	Flat bed delivery truck	Street Maintenance Department
5	242 Front Avenue (Chesapeake & Ohio Railroad)	**West Side** - RR Bridge between Emperor and Butterworth Streets	The top off railroad ballast is slightly below the BFE.	24.5	608.6	Construct 50' of sandbag berm across railroad property and connect to the permament flood control walls. Coordinate with CSX Transportation.	• Sandbags = 1,500 • Sand = 14 cyd	Flat bed delivery truck	Street Maintenance Department
6	Fulton/Monroe/Market Avenue Intersection	**East Side** - Fulton/Monroe/Market Avenue Intersection	This area is below the BFE and not connected to a stormwater pumping station. When the flap gates are closed during extreme flooding events the area is susceptible to flooding during rainfall events that occur during the flood.	23.5	607.6	Connect portable pumps to quick connect located in chamber outside the curbline at the northeast corner of the intersection and pump water from intersection. (Pump hose to fit Andrews #600B 6" male N.P.T. aluminum quick coupler)	• Sandbags = 3,000 • Sand = 28 cyd	• Portable trailer-mounted pumps • Flat bed delivery truck • Fork lift	• Traffic Safety • Environmental Services Department
7	Bond Avenue at Newberry Street	**East Side** - Bond Avenue at Newberry Street	This area is below the BFE and not connected to a stormwater pumping station. When the flap gates are closed during extreme flooding events the area is susceptible to flooding during rainfall events that occur during the flood.	24.0	612.7	Drain area with portable pumps.	• Sandbags = 3,000 • Sand = 28 cyd	Portable pumps	• Street Maintenance Department • Environmental Services Department
8	624 Front Avenue (Fish Ladder Park)	**West Side** - Front Avenue and 4th Street	The sidewalk from the parking lot to the Fishladder is not high enough for extreme flood events.	23.5	611.0	Erect closure by placing aluminum stop logs into guides cast in retaining walls on either side of the sidewalk.	Aluminum stop logs stored at Front Avenue Stormwater Pumping Station	Flat bed delivery truck	Environmental Services Department
9	678 Front Avenue	**West Side** - Floodwall 340' south of 6th Street	4" core in floodwall for riverwalk drainage	21.0	609.6	Install 4" inflatable sewer plug; or place 30 sandbags behind the floodwall to plug the hole.	• 4" inflatable sewer plug = 1 • Sandbags = 30	Small air compressor	Environmental Services Department
10	Myrtle Street from Grand River to Scribner Avenue	**West Side** - Myrtle Street from Grand River to Scribner Avenue	This area is below the BFE and not connected to a stormwater pumping station. When the 24" flap gate at Myrtle Street is closed during an extreme flood event this area is susceptible to shallow flooding during rainfall events that occur during the flood.	20.0	611.0	Drain area with portable pumps.	• Sandbags = 10,000 • Sand = 195 cyd	Portable pumps	Environmental Services Department

Appendix A

Plans for Training, Exercising, Updating and Posting EAP

Annual Training of Project Operators and Other Responsible Personnel

All divisions as determined by the City Incident Commander (see Watch and Warning Emergency Notification Flowcharts, Pages 1 and 2) are responsible for the training of operating and supervisory personnel to assure timely and adequate assessments of developing emergency situations and performance of their duties in the event of an emergency situation. Each individual is to be instructed as to what conditions constitute a project emergency and what specific responsibility they are to execute.

The City Incident Commander (City Manager) and the Kent County Emergency Management & Homeland Security Office are responsible for conducting annual refresher seminars, workshops, or meetings for this EAP.

Annual Review and Test of State of Readiness

At least once a year, the City Incident Commander (City Manager), City Engineer, Environmental Services Manager, Public Services Director, Water Systems Manager, and Kent County Emergency Management & Homeland Security Office, will meet and perform a test to simulate a levee/floodwall failure (Watch or (Warning). The test will be initiated when the City Engineer contacts the City Incident Commander (City Manager) and the Kent County Emergency Management & Homeland Security Office telephone numbers to advise that a test of the emergency alert system for a problem at the GRFPS is being conducted. Every participant in the EAP will execute their required actions as if it were a real emergency. When executing the drill, each person in the contact network should give their name and position and state that this is only a drill and repeat that this is only a drill. In no case shall the news media be notified.

Once everyone in the (Watch or Warning) networks has been contacted, the Kent County Emergency Management & Homeland Security Office will notify the City Incident Commander (City Manager) that all contacts have been made. The City Incident Commander (City Manager) then cancels the test and directs the City Engineer to notify the EAP plan participants of the completion of the test.

Each year, the test of the emergency contact network should be carried out at different times of the day and night and different months to observe the efficiency of the EAP under all situations.

After the drill, the City Incident Commander (City Manager) and Kent County Emergency Management & Homeland Security Office will determine if the test was successful. They will check names, titles, telephone numbers, radio logs, and any other information that is vital to the execution of the EAP. Any revisions to the emergency contact networks for a (Watch and Warning) condition will be made immediately after this review.

Posting

This EAP shall be filed in an area within each participant’s place of work where it is easily accessed and identified. During the annual test of the EAP, the City Incident Commander (City Manager) shall specifically request each participant to verify that they have been able to easily find their copy of the EAP.

Appendix B

Site Specific Concerns

Drain Pipe Backflow Prevention

There are 90 drain pipes that extend through the levee embankment and floodwall along the Grand River and Indian Mill Creek (see the Closure Evaluation Report for pipe locations). Every drain pipe has either a flap gate or a duckbill check valve on its outlet end or in manholes upstream of the river. In some cases, there are no flap gates or duckbill valves; however, manhole covers upstream of the outlet are bolted down to prevent flooding. In the event that a flap gate or duckbill valve is jammed open due to ice, debris, impact damage, or vandalism, the Environmental Services Department and Public Services Department must be prepared to shut-off these pipes at the inlet end. This could be accomplished by inserting an inflatable plug into the inlet. During a flood event where the outlet ends of the pipes are submerged, the Environmental Services Department and Public Services Department should monitor the level of water in these pipes to determine if it is rising in the pipes. If the water is rising, it may indicate that the flap gate on the outlet end of the pipe has not seated and the need to shut-off these pipes at the inlet end.

Appendix C

Statement of Purpose

The purpose of this Flood Protection Emergency Action Plan (EAP) is to minimize the hazard to life and property during a flood emergency event in the City of Walker, Michigan (City). The functionality of the City's response to any emergency situation is dictated by the National Incident Management System (NIMS) with an Incident Commander (City Manager) responsible for weighing the responsibility for each City department. This EAP is a subpart of this command structure. This Flood Protection EAP is specific to a flood emergency and should be coordinated with the overall emergency response provisions of the City's emergency action guidelines included in the City of Walker and Kent County Emergency Management Agreement dated May 3, 2019.

The City, which lies on the west bank of the Grand River and surrounds the portion of the City of Grand Rapids on the west bank of the river and also borders Alpine and Plainfield Townships (Kent County) to the north, the cities of Grandville and Wyoming (Kent County) to the south and Tallmadge Township (Ottawa County) to the west could be flooded to varying degrees depending on the water level in the Grand River and the nature of an unusual or emergency event. The flood protection measures constructed in the City are an extension of the City of Grand Rapids Grand River Flood Protection System (GRFPS) extending from the on/off ramps of US-131 to 4,530 feet north along US-131 as shown on Figure 4. Should the City experience an emergency event that exceeds the GRFPS level of protection, portions of the protected area could be inundated by flood waters. In addition to residential structures (including their contents) and public infrastructure (roadways, railroads, and utilities), industrial facilities, and commercial establishments could be damaged.

Communication of the emergency situation will be on cellular telephones with the Kent County 800 MHz Radio System as a backup. All City, County, and State officials will observe rules of jurisdiction and proper chains of command.

City departments are responsible for monitoring the situation during major floods, when a potentially hazardous condition is developing, and when levee and/or floodwall failure is imminent or has occurred. City departments will respond in accordance with this document. Refer to the Emergency Notification Chart Figures 1 and 2. It is the responsibility of every Flood Protection EAP participant to be fully aware of his/her duties and to execute those duties to the best of their ability.

System Description

The GRFPS in the City is part of Reach W1 of the larger City of Grand Rapids GRFPS and consists of a combination of two types of protective structures built along the banks of the Grand River. These protective structures may be generally classified as: 1) concrete flood walls atop embankments and 2) low earth levees/embankments constructed atop natural stream banks. The interior flood control system consists of one pump station (located in the City of Grand Rapids), the storm water collection system, and a series of floodwall backflow devices on outfalls that drain to the Grand River. Under non-flood conditions in the Grand River, storm water discharges directly to the river through outfall penetrations through embankments, natural stream banks and US-131. In the event that flood stages in the river are high enough to close the backflow devices on the storm water drain outlets, the storm water flow is diverted to the Indian Mill Creek Pump Station in the City of Grand Rapids.

The GRFPS for Reach W1 was designed to protect approximately 170 acres (119 acres in the City of Walker) on the right (west) bank of residential, commercial, institutional, and industrial properties from up to the 100-year flood. The project provides pumping capacity, stormwater interceptors, and gravity outfalls to discharge interior runoff during a rainfall event. Within the City, the GRFPS consists of 4,530 feet of natural ground and embankment between the Grand Rapids/Walker city boundary at the US Route 131 exit ramps north of Nason Street NW to the railroad tracks near the intersection of West River Drive and Lankamp Street. The location of the GRFPS in the City is shown in Figure 3. Although there are no storm water pump stations in the City, storm water

from the area protected by the GRFPS in the City is directed to the Indian Mill Creek Storm Water Pump Station in Grand Rapids. The Indian Mill Creek Storm Water Pump Station has 3 pumps with a discharge capacity of 4,500 gallons per minute (gpm) and is located along Indian Mill Creek upstream of the confluence with the Grand River at the west end of parking lot on the south side of Ann Street for the building at 400 Ann Street. The location of drainage pipes that penetrate the levee embankment and natural ground are shown in Figure 4.

Emergency Detection, Evaluation, and Classification

Definition of Terms

- *Warning*: The flood stage is 18-feet or above as measured at the U.S. Geological Survey (USGS) gage upstream of the Fulton Street Bridge ("Gauge 0" Datum: 585.25 NAVD88). Alternatively, the levee, floodwall, or drain pipe backflow prevention devices have failed or actual failure is in progress and immediate warnings to evacuate are required. A (Warning) condition is the primary focus of this EAP.
- *Watch*: The flood stage is 12-feet and predicted to continue rising ("Gauge 0" Datum: 585.25 NAVD88). Alternatively, a condition exists that could potentially develop into an unsafe condition, but the immediate safety of the levee and/or floodwall is not in jeopardy. The deficient condition should be monitored closely, and a licensed professional engineer familiar with levee and floodwall safety should be contacted to recommend remedial measures. Provisions for addressing deficient conditions are included in the Operations, Maintenance, and Inspection Manual.

Inspection

The levee, floodwall, embankment, retaining walls and backflow prevention devices should be inspected as required by the Operations, Maintenance, and Inspection Manual. The person(s) responsible for maintaining and/or inspecting the levee and floodwall should be familiar with this section.

High Water Levels

The City of Walker is subject to rising water levels depending on climatic and meteorological factors. There is an automatic water level recorder operated by the USGS along the west bank of the Grand River between the Fulton Street Bridge and the Blue Pedestrian Bridge in Grand Rapids (USGS Station No. 04119000) to determine the current state of the water levels.

Several water levels have been established to trigger specific actions by the City:

- USGS gauge water level = 12-feet (elevation 597.25-feet NAVD88) and rising: (Watch) Alert issued for City Departments and Public Works Department begins road closure installations starting with Turner Avenue.
- USGS gauge water level = 18-feet (elevation 603.25-feet NAVD88) and rising: City Incident Commander (City Manager) issues (Warning) Alert and Kent County Emergency Management & Homeland Security begins to set up Command Center at the Kent County Sheriff's Office
- USGS gauge water level = 21-feet (elevation 606.25-feet NAVD88): Command Center at Kent County Sheriff's Office fully operational

Regular "walk-by" inspections as performed by the Department of Public Works should occur daily when the Grand River is at a flood level sufficient to trigger the high water (Warning) Alert by the City Manager. Visual observations from inspections should be documented to establish current event baseline conditions, any developing conditions, or damage assessment.

Potential Levee Problems

Almost all levee failures can be directly related to seepage, piping, sediment loss, slope failure, settlement, or problems related to conduits through the levee embankment. Although the City's levees are relatively short in length, the problems inherent in levee design and construction still require vigilance. Each of these potential levee problems is discussed in the following paragraphs.

Seepage

Depending on the water depth and duration of a particular water depth in a stream, all levees normally experience a minor degree of seepage as water from the stream seeks paths of least resistance through the levee embankment and the levee foundations. However, excessive seepage or seepage that is visually different than previously observed can be indicative of major problems within the levee embankment and the levee foundations. Seepage must be controlled in both velocity and quantity. Along the GRFPS in the City, seepage is most likely to occur along the embankment opposite the embankment for southbound lanes of U.S. Route 131.

Indicators

- Appearance of wet spots or springs in the protected (dry) face of the earth embankment or in areas immediately adjacent to the toe of the embankment
- Areas that prematurely thaw, or where snow melts prematurely during the winter
- Areas of wetland-type vegetation (reeds, cattails, etc.) along the protected (dry) side toe of the levee embankment
- Boils, seepage, piping (fine-grained material being ejected in a stream of water out of a hole in the levee embankment forming a small cone of material), appearing on the protected (dry) face of the levee embankment or in the area adjacent to the protected (dry) side toe of the embankment
- Sinkholes or depressions occurring on the levee embankment or in the area adjacent to the toe of the embankment slope
- Landslides on the protected (dry) side face of the levee embankment. Note that shallow depth landslides are not always caused by seepage
- Depressions formed in either side of the levee embankment and the levee crest including unusual localized cracking of the road service atop the embankment. Depressions could also form along the paths of the buried drain pipes through the levee embankment
- The appearance of a persistent whirlpool (vortex) in the Grand River adjacent to the levee embankment during a high water event

Reporting

Reporting and documentation of potential levee and floodwall problems should be completed in accordance with the inspection forms included in Appendix 2 of the Operations, Maintenance & Inspection (OM&I) Manual. Note that current river stage information can be obtained from the National Weather Service (NWS) Forecast Office, Grand Rapids, Michigan, Advanced Hydrologic Prediction Service at:

http://water.weather.gov/ahps2/hydrograph.php?wfo=grr&gage=gdrm4

or the USGS Michigan Water Science Center at:

http://waterdata.usgs.gov/mi/nwis/sw

Piping of foundation and/or embankment material is normally indicated by a buildup of materials around the seepage area or a slope failure (e.g. boils, slumps, landslides, sinkholes). Catching some seepage water in a clear glass jar and looking through the water can often indicate particles in suspension during the initial stages of piping. If the seepage velocity is high, the water may just be cloudy or muddy and buildup of materials may be some distance from the actual seepage location. After the seepage is reported, the area should be photographed before any measures are taken to control the problem. Disturbance of any seepage indicator, such as the buildup of sediment around the seepage area, should be kept to a minimum. Any occurrence of a persistent (not dissipating and/or moving downstream) whirlpool in the Grand River adjacent to the levee and/or floodwall is an emergency (Warning) condition.

Temporary Controls (until more permanent repairs can be made)

- Changes in Seepage, Boils, and Whirlpools
  - Observe for various stream levels to determine the approximate elevation that initiates seepage and the location of the seepage source.
  - If the source of the seepage can be found or a suspected location identified, place a blanket of impervious material such as bentonite clay over the seepage source.
  - If the seepage is persistent, install a grout curtain inside the levee embankment or along the river face of the floodwall.
- Boils
  - Place a ring of sandbags or a large diameter pipe around the boil area to pond water above the ground surface at the boil location and reduce the velocity of the water emanating from the boil.
  - Never dump sand or similar material into a boil until an assessment of the sediment in the boil can be completed.
  - After an assessment of the sediment associated with the seep or boil, an overlay of an approved granular material may be selected as a control measure.
- Sinkholes, Settlement, and Depressions
  - The cause of any sinkholes, settlement, and depressions should be investigated by a qualified geotechnical engineering firm.
  - After documenting the location of sinkholes, settlement, or depressions, they should be filled with earth or rocks until more permanent measures can be taken to resolve the problem.
  - The option exists to perform a temporary control as recommended by a licensed professional engineer with expertise with flood control and safety and approved by the City Engineer.

Slope Failure

In general, slope failures occur gradually, and if detected in the early stages, measures can be taken to prevent total embankment failure. On the river (wet) levee and embankment slopes, failures may occur shortly after a rapid decrease in the river level following a protracted flood. On the protected (dry) levee slope, failures may occur after large rainfall events following a protracted period of hot, dry weather where the levee soils shrink and crack, allowing water to penetrate the surface instead of normally infiltrating. Slope failures can also occur in multiple areas and at different times, but are more likely during special operating or loading conditions or during extended periods of heavy rainfall. They may be initiated by excessive vibrations, seepage, earthquakes, or erosion. Massive slides can initiate catastrophic failure of a levee.

Indicators

- Slumping, sloughing, or sliding of soil material on either the river (wet) face or protected (dry) face of the levee or embankment.
- Cracking of the road pavement atop the levee or embankment
- Cracks in the levee or embankment. Transverse cracks appear across the levee or embankment and might indicate differential settlement within the embankment. Such cracks provide avenues for seepage water and piping could quickly develop. Longitudinal cracks run parallel to the levee or embankment and may signal the early stages of a slide or slump on either face of the embankment.
- Erosion of the river (wet) side or protected (dry) side of the levee or embankment caused by a rapid decrease in the river level following a protracted flood, rainfall, runoff, snow melt, river currents, wave action, lack of vegetation, foot-traffic, overtopping, or increased seepage through the levee or its foundation. Deep erosion gullies and levee waterline erosion can threaten the structural integrity of the embankment. Erosion along the base of the levee indicates potential deterioration of the foundation that could result in landslides or misalignment of the embankment.

Reporting

Reporting and documentation of potential levee and floodwall problems should be completed in accordance with the inspection forms included in Appendix 2 of the OM&I Manual.

Temporary Controls (until more permanent repairs can be made)

- Slumps/Sloughs/Landslides/Erosion/Settlement
  - For slumps, sloughs, erosion, and settlement on the levee embankment, or at the toe of the embankment slope, fill the affected area with soil, rockfill, or sandbags until more permanent repairs can be made.
  - On the protected (dry) face of the levee embankment, cover the repaired area with plastic sheets or other erosion-resistant materials to prevent subsequent erosion during storms.
  - For landslides, stabilize the toe of the slide by weighting with soil, rock, or gravel. If necessary, fill materials should be placed at the top of the slide to restore freeboard after the toe is stabilized.
- Cracks
  - Fill non-leaking cracks in the levee embankment with soil, rocks, cement grout, or sandbags until more permanent repairs can be made.
  - Improve (line) the drainage path from the crack to prevent further erosion.
  - A leaking crack is an emergency (Warning) situation. The crack should be filled immediately with an available material including bentonite clay, soil, hay bales, sandbags, and rocks to stop or slow the flow of water until the stream level recedes and a permanent repair is made.
- Levee Overtopping
  - If it is apparent that the levee or embankment will be overtopped, this is an emergency (Warning) situation. The City Incident Commander and Kent County Emergency Management & Homeland Security Office should be notified to initiate evacuation procedures for the areas potentially affected by the coming flood.

Settlement

Settlement is the decrease in elevation of soil from its originally constructed elevation. To a certain degree, settlement of a levee embankment is normal and to be expected. Often settlement occurs because the soil was not fully compacted beneath a road surface atop a levee or embankment. Settlement is most likely to occur along the levee crest, adjacent to pipe outfalls, and at the interface between the levee embankment and natural ground. Settlement of the ground may also result from gypsum voids in the underlying bedrock. Settlement along the path of drain pipes through the levee, which could be an indication that material is being removed within the levee along the pipe, is most likely and an emergency (Warning) situation.

Indicators

- A noticeable slump in the levee embankment crest.
- Cracking of the road surface atop an embankment or levee
- Depression in the ground along the path of the drainage pipes.
- Depression at the interface between the levee embankment and natural ground.

Reporting

Reporting and documentation of potential levee and floodwall problems should be completed in accordance with the inspection forms included in Appendix 2 of the OM&I Manual.

Temporary Controls (until more permanent repairs can be made)

- Sandbags
  - Install sandbags in accordance with the Operations, Maintenance and Inspection Manual.
- Areas where settlement has occurred that are not actively continuing to settle should be filled with clay-type soil to return the levee crest or face to the as-constructed elevation. The clay-type soil should be compacted to 95 percent or above of maximum dry density at 1 percentage point below to 3 percentage points above optimum moisture content based on the Standard Proctor Density Test (ASTM D 698-78).
- Settlement may constitute a (Warning) and the City Engineer should be notified.

Backflow Device Problem

The flap gates on the ends of the drainage pipes through the levee and embankment sections of the GRFPS are exposed to the flow in the Grand River and could be damaged or clogged by floating debris and ice impact.

Indicators

- Water flowing from storm sewer manholes and/or street stormwater inlets during high water conditions in the Grand River. This will typically be seen as water flowing down a street emanating from a manhole cover or catch basin; or ponding water at any location around a manhole cover or catch basin.

Reporting

Reporting and documentation of potential levee problems should be completed in accordance with the inspection forms included in Appendix 2 of the OM&I Manual.

Temporary Controls

- Drainage Pipes through Levee and Floodwall
  - If a flap gates is not operating properly, the inlet end of the pipe should be sealed using an inflatable plug. If this is not possible sandbags can be placed around all catch basin inlets and manhole covers below the projected high water elevation. Once the water level subsides in the Grand River, the flap gates should be unclogged, repaired, and/or replaced.

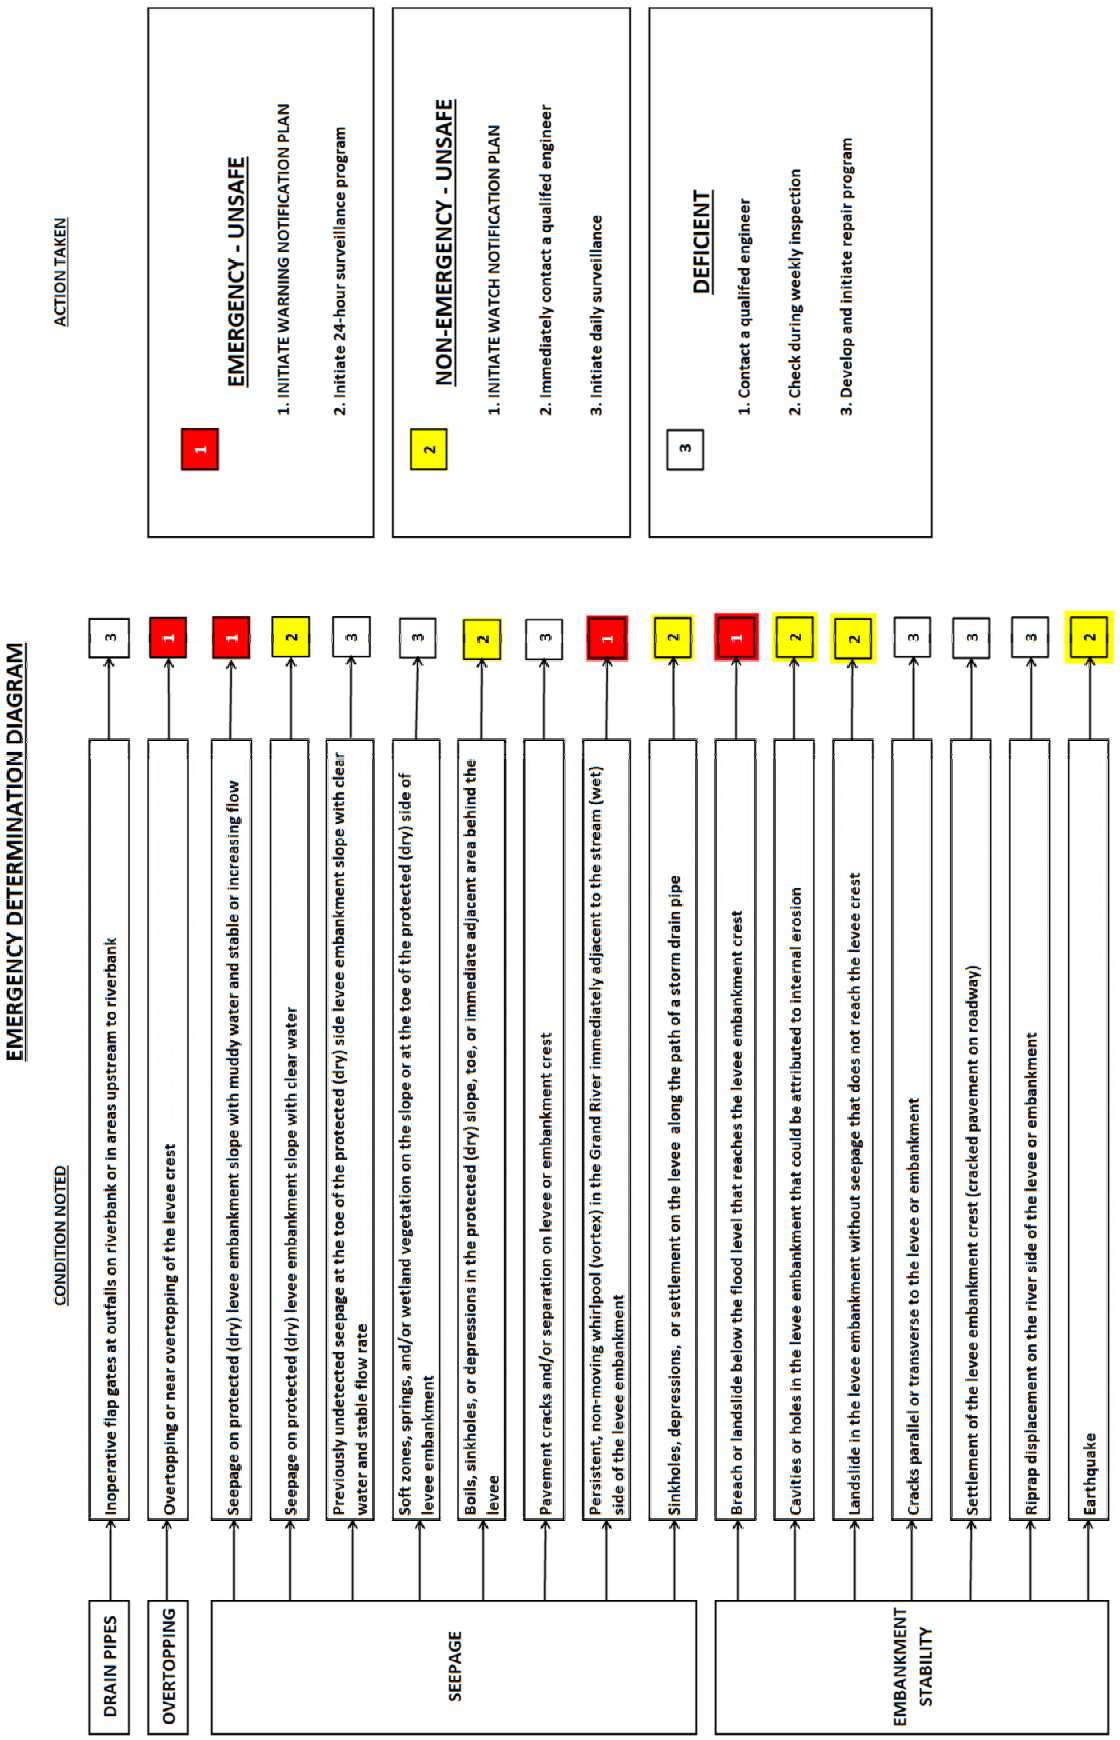
Additional Comments

The types of levee failures described above are often interrelated in a complex manner. For example, uncontrolled seepage may weaken the soil and lead to a slope failure. A slope failure may shorten the seepage path and lead to a piping failure. Minor defects such as cracks in the levee embankment may be the first visual sign of a major problem that could lead to failure of the structure. A licensed professional engineer experienced in levee design and construction should evaluate the seriousness of all deficiencies and recommend appropriate permanent remedial measures.

Whenever a potential emergency situation is reported, the City Engineer or his/her designee should immediately visit the area of concern at the GRFPS and evaluate the situation as described in the above paragraphs. If the situation is severe enough that there is any concern that there could be an uncontrolled release of water into the area protected by the GRFPS, the City Engineer shall initiate a levee failure (Warning) alert in accordance with the Emergency Notification Chart in Figures 1 and 2.

If upon visiting the potential problem area at the GRFPS, the City Engineer or his/her designee determines that the situation can be handled without danger of an uncontrolled release of water into the area protected by the GRFPS, the necessary work should be coordinated by the City Engineer with the asset management plan inspections, updates, and improvements.

Once a levee and/or floodwall problem progresses to the point that the levee and/or floodwall is failing, evacuation in the flood inundation zone, (see Inundation Map in Figure 5), may be necessary if emergency actions do not appear to be adequate to prevent flooding in the protected area.



EMERGENCY DETERMINATION DIAGRAM
CONDITION NOTED
ACTION TAKEN
DRAIN PIPES
OVERTOPPING
SEEPAGE
EMBANKMENT STABILITY
Inoperative flap gates at outfalls on riverbank or in areas upstream to riverbank
Overtopping or near overtopping of the levee crest
Seepage on protected (dry) levee embankment slope with muddy water and stable or increasing flow
Seepage on protected (dry) levee embankment slope with clear water
Previously undetected seepage at the toe of the protected (dry) side levee embankment slope with clear water and stable flow rate
Soft zones, springs, and/or wetland vegetation on the slope or at the toe of the protected (dry) side of levee embankment
Boils, sinkholes, or depressions in the protected (dry) slope, toe, or immediate adjacent area behind the levee
Pavement cracks and/or separation on levee or embankment crest
Persistent, non-moving whirlpool (vortex) in the Grand River immediately adjacent to the stream (wet) side of the levee embankment
Sinkholes, depressions, or settlement on the levee along the path of a storm drain pipe
Breach or landslide below the flood level that reaches the levee embankment crest
Cavities or holes in the levee embankment that could be attributed to internal erosion
Landslide in the levee embankment without seepage that does not reach the levee crest
Cracks parallel or transverse to the levee or embankment
Settlement of the levee embankment crest (cracked pavement on roadway)
Riprap displacement on the river side of the levee or embankment

Emergency Action

Emergency Action by River Stage

As the Grand River rises in the City, various actions are required to protect areas of the City from inundation by flood waters. Table 1 provides a list of actions by river stage that need to be performed. Note that Table 1 should be reviewed annually to ensure that it is up to date and reflects any modification to the GRFPS.

Preparedness

Levee Owner

The City is responsible for levee inspections as outlined in the City Operations and Maintenance Manual. The City is also responsible for detecting emergency conditions and depending on the observed conditions, he/she is responsible for deciding the appropriate action under the NIMS Incident Commander and the appropriate Emergency Notification Chart in Figures 1 and 2 and in cooperation with the Engineering Department, Public Works Department, Police Department, and Fire Department.

If flood (Watch) non-emergency conditions are predicted based on local observations and consultation with the NWS in Grand Rapids, the City Engineer should contact the Public Works Department to prepare to monitor levee and embankment conditions along the Grand River. If the water level reaches the (Watch) non-emergency condition and is continuing to rise, or if notification from the City Incident Commander and/or Kent County Emergency Management & Homeland Security Office is received, the Public Works Department shall prepare to install the temporary flood control measures as described in Table 1. Personnel from the City Engineer's Office and Public Works Department should inspect the levee, embankment, drainage structures and backflow prevention devises daily to ensure that no problems are occurring that would trigger an emergency response. In the case that problems are detected, the problem area should be continuously monitored until the flood subsides and remedial measures can be implemented. After the flood subsides, the City Engineer's office should conduct an inspection of the levee, embankment, drainage structures and backflow prevention devices to determine if any damage has occurred that requires repair.

During a flood watch or warning situation, the City Incident Commander (City Manager) should stay in contact with the City of Grand Rapids Incident Commander (City Manager) to coordinate actions regarding the preparation and operation of the GRFPS including but not limited to the sharing of equipment and materials if needed.

During flooding of the Grand River, the curious public and news media can create a major obstacle to performance of necessary tasks; therefore, levee access control measures should be taken. In conjunction with any evacuation of residents in the area protected by the GRFPS, it will be necessary to provide easy access for equipment, supplies, and personnel involved in the effort to affect repairs. The City Engineer and Public Works Department should work closely with the City Incident Commander and Police and Fire Departments to prevent unauthorized access to the GRFPS and to facilitate movement of necessary equipment, supplies, and personnel to the levee and embankment.

Notification

In the event of a flood (Warning) emergency condition or problems with the GRFPS, it is the shared responsibility of the Walker City Engineer and Walker Public Works Director to notify the Walker Incident Commander (City Manager) and Kent County Emergency Management & Homeland Security Office and brief them on the situation. The Kent County Emergency Management & Homeland Security Office will prepare and deliver a message for public release based on the existing conditions and information provided by the Walker City Engineer and Walker Incident Commander (City Manager). Preparation of (Warning) emergency messages should begin as soon as their potential need is apparent so that they can be issued promptly upon declaration of a (Warning) emergency condition. When time is available for their preparation, the initial message should contain all pertinent information. However, in some cases a (Warning) emergency condition may be declared with little or no advance notice. The following sample messages provide models for the first announcement in such cases. Subsequent announcements should provide additional details.

Announcement of Levee Failure in Progress

Urgent, Urgent: The City has announced that a portion of the levee along the Grand River (has failed/is in imminent danger of failure).

Attempts to stabilize the levee are underway, but their success cannot be determined as of yet. Residents living in the following areas should evacuate to high ground immediately:

- Name of area (location and extent)
- Name of area (location and extent)
- Name of area (location and extent)

Additional information will be released as soon as possible.

Announcement of Flood Crest Above Flood Protection Level

Urgent, Urgent: The City has announced that the Grand River is expected to crest at elevation (insert elevation), which is (insert number of feet) above the top of the flood protection levees and floodwalls in the City.

Residents living in the following areas should evacuate to high ground immediately:

- Name of area (location and extent)
- Name of area (location and extent)
- Name of area (location and extent)

Additional information will be released as soon as possible.

The simplest functioning means of communications will be used to maintain communications with authorities and construction contractors retained to stabilize the levee and/or floodwall. Notification will normally be on the Kent County 800 MHz Radio System or by cellular telephones.

The NWS will also be a primary source through which emergency announcements are released to the news media.

National Weather Service (Grand Rapids, Michigan): 24-hour telephone number (616)949-0643

The following radio and television stations should be contacted if the NWS cannot be contacted. These stations are considered to have broadcast areas covering Walker.

Evacuations

The City Incident Commander, Kent County Emergency Management & Homeland Security Office, and Walker Police Department, are responsible for evacuation of the flood inundation area. The City Incident Commander and/or Kent County Emergency Management & Homeland Security Office will also contact the Kent County Sheriff and Michigan State Highway Patrol for area coordination, as needed. The City Engineer should not assume responsibility for evacuation but should coordinate with the appropriate officials.

Termination and Follow-Up

The City Engineer should monitor the emergency situation at the GRFPS and keep the City Incident Commander informed of developing conditions. The City Incident Commander and the Kent County Emergency Management & Homeland Security Office are responsible for terminating the (Watch) non-emergency condition or the (Warning) emergency condition for the area protected by the GRFPS.

Following the emergency situation, the City Engineer is responsible for performing a follow-up evaluation of this Flood Protection EAP with the participants involved in the emergency.

Flood Protection EAP Coordination

The City Engineer is responsible for the coordination of this Flood Protection Project EAP. The responsibility encompasses the following items:

- Revisions to the Flood Protection EAP.
- Coordination of Flood Protection EAP exercises in cooperation with the City Incident Commander and Kent County Emergency Management & Homeland Security Office and the City of Grand Rapids Incident Commander
- Establishment of Flood Protection EAP training seminars for the City Engineer's Office, Public Works Department, and City Incident Commander.
- Serving as the Flood Protection EAP contact for emergencies (Warning) and non-emergencies (Watch) related to the GRFPS. The City Engineer may delegate this responsibility to the Police Chief and/or Fire Chief as necessary to efficiently coordinate the emergency response.

Access to the GRFPS

The primary route of access to the GRFPS is from West River Drive, Turner Avenue, and U.S. Route 131.

Response During Periods of Adverse Weather

During periods of adverse weather, the City Engineer should be prepared to isolate and protect areas of potential levee repair from rainfall, ice, and snow. This includes stockpiling repair materials, including sandbags, sand, plastic sheets, gravel, and clay soil, and having a list of available contractors, equipment, and equipment operators, including portable lighting, generators, heavy-duty electric cords, and earth moving equipment (skid steers, backhoes, front end loaders, bulldozers, etc.).

Response During Periods of Darkness

For emergency situations that occur at night, the City Engineer and/or Public Works Department, shall provide lighting, either fixed or portable, for the GRFPS that is sufficient to illuminate the site. At least three or more portable generators, maintained in good working order, are to be provided for use in levee and/or drainage structure failure emergencies. The generators and associated electrical cords shall be capable of providing power to any emergency electrical equipment including emergency lighting and have an output capacity that meets or exceeds the power required by emergency equipment.

Alternate System of Communications

Cellular telephones are to be used as an alternate means of communications.

Emergency Supplies and Resources

For emergency use, the City Engineer and Public Works Department shall have the following materials and supplies available at their respective facilities with sufficient transport vehicles to ensure a timely response to an emergency situation:

- Flashlights to provide lighting where emergency lighting does not illuminate and for directing traffic
- Portable, petroleum-fueled generator(s)
- Extension cords (heavy duty) for use with the portable generators and emergency equipment including lights
- Fire extinguishers (preferably type ABC) for extinguishing any fire that may occur in the emergency equipment
- Portable electric floodlights
- Fill material to dump into any levee breach and to fill sandbags
- Sandbags
- Backhoe, trackhoe, front end loader, and/or skid steer for hauling and placing fill material
- Four-wheel drive vehicle and dump truck for hauling fill material and equipment
- One or more portable pumps with flexible hoses to assist in pumping water from the pump station wet wells in the event that one or more pumps become disabled
- Plastic sheets for temporary crack repair and for protecting eroded areas on the levee embankment
- Rope to assist emergency personnel
- Personal flotation devices
- First aid kit
- Traffic control cones and/or barriers

A list of available City equipment for emergency operations is included in Appendix C.

Emergency Contractors and Suppliers

The City should have sufficient personnel, equipment, and materials to respond to emergencies at the GRFPS. In the event that additional personnel and equipment is required at the GRFPS site, the City Engineer shall procure the required services on an emergency basis. A list of emergency response contractors is provided in Appendix D.

5	Road Closure (outside the GRFPS)	Riverbend Drive between Butterworth Sreet and Veterans Memorial Drive	When the river rises, the street may become impassable	12.0	593.7	Barricade Road	Road Barricades, Traffic Cones, Warning Signs	None	Public Works Department

Appendix A

Plans for Training, Exercising, Updating and Posting EAP

Training of Project Operators and Other Responsible Personnel

All divisions as determined by the City Incident Commander (see Watch and Warning Emergency Notification Flowcharts, Pages 1 and 2) are responsible for the training of operating and supervisory personnel to assure timely and adequate assessments of developing emergency situations and performance of their duties in the event of an emergency situation. Each individual is to be instructed as to what conditions constitute a project emergency and what specific responsibility they are to execute.

The City Incident Commander (City Manager) and the Kent County Emergency Management & Homeland Security Office are responsible for conducting annual refresher seminars, workshops, or meetings for this Flood Protection EAP.

Review and Test of State of Readiness

At the occurrence of a change in the Walker City Incident Commander (City Manager) or Fire Chief, the City Incident Commander (City Manager), City Engineer, Public Works Director, Fire Chief, and Kent County Emergency Management & Homeland Security Office, will meet and perform a test to simulate a levee failure (Watch or (Warning). The test will be initiated when the City Engineer contacts the City Incident Commander (City Manager) and the Kent County Emergency Management & Homeland Security Office telephone numbers to advise that a test of the emergency alert system for a problem at the GRFPS is being conducted. Every participant in the Flood Protection EAP will execute their required actions as if it were a real emergency. When executing the drill, each person in the contact network should give their name and position and state that this is only a drill and repeat that this is only a drill. In no case shall the news media be notified.

Once everyone in the (Watch or Warning) networks has been contacted, the Kent County Emergency Management & Homeland Security Office will notify the City Incident Commander (City Manager) that all contacts have been made. The City Incident Commander (City Manager) then cancels the test and directs the City Engineer to notify the Flood Protection EAP plan participants of the completion of the test.

After the drill, the City Incident Commander (City Manager) and Kent County Emergency Management & Homeland Security Office will determine if the test was successful. They will check names, titles, telephone numbers, radio logs, and any other information that is vital to the execution of the EAP. Any revisions to the emergency contact networks for a (Watch and Warning) condition will be made immediately after this review.

Posting

This Flood Protection EAP shall be filed in an area within each participant's place of work where it is easily accessed and identified. During the annual test of the Flood Protection EAP, the City Incident Commander (City Manager) shall specifically request each participant to verify that they have been able to easily find their copy of the EAP.

Appendix B

Site Specific Concerns

Drain Pipe Backflow Prevention

There are 7 drain pipes that extend through the levee embankment and natural ground along the west side of US-131 and the Grand River (see Figure 4 for pipe locations). Every drain pipe has a flap gate on its outlet end. If a flap gate is jammed open due to ice, debris, impact damage, or vandalism, the Public Works Department must be prepared to shut-off these pipes at the inlet end. This could be accomplished by inserting an inflatable plug into the inlet or isolating the subject catch basin inlets and manhole covers with rings of sandbags. During a flood event where the outlet ends of the pipes are submerged, the Public Works Department should monitor the level of water in these pipes to determine if it is rising in the pipes. If the water is rising, it may indicate that the flap gate on the outlet end of the pipe has not seated and the need to shut-off these pipes at the inlet end.

Appendix C

Appendix E

Turner Avenue Flood Control Procedure

Appendix E
Turner Avenue Flood Control Procedure

April 1, 2018, Revised January 2020
By: FTCH (JRP)

Reference USGS Stream Gage: 04119000 (NOAA GDRM4) Grand River at Grand Rapids, MI (GRR)
Location: West side of the Grand River just south of the Blue Bridge.
https://water.weather.gov/ahps2/hydrograph.php?wfo=grr&gage=gdrm4

At the Walker/Grand Rapids City Limits the 100-Year Flood Stage = 25.36' = 616.80 NAVD88

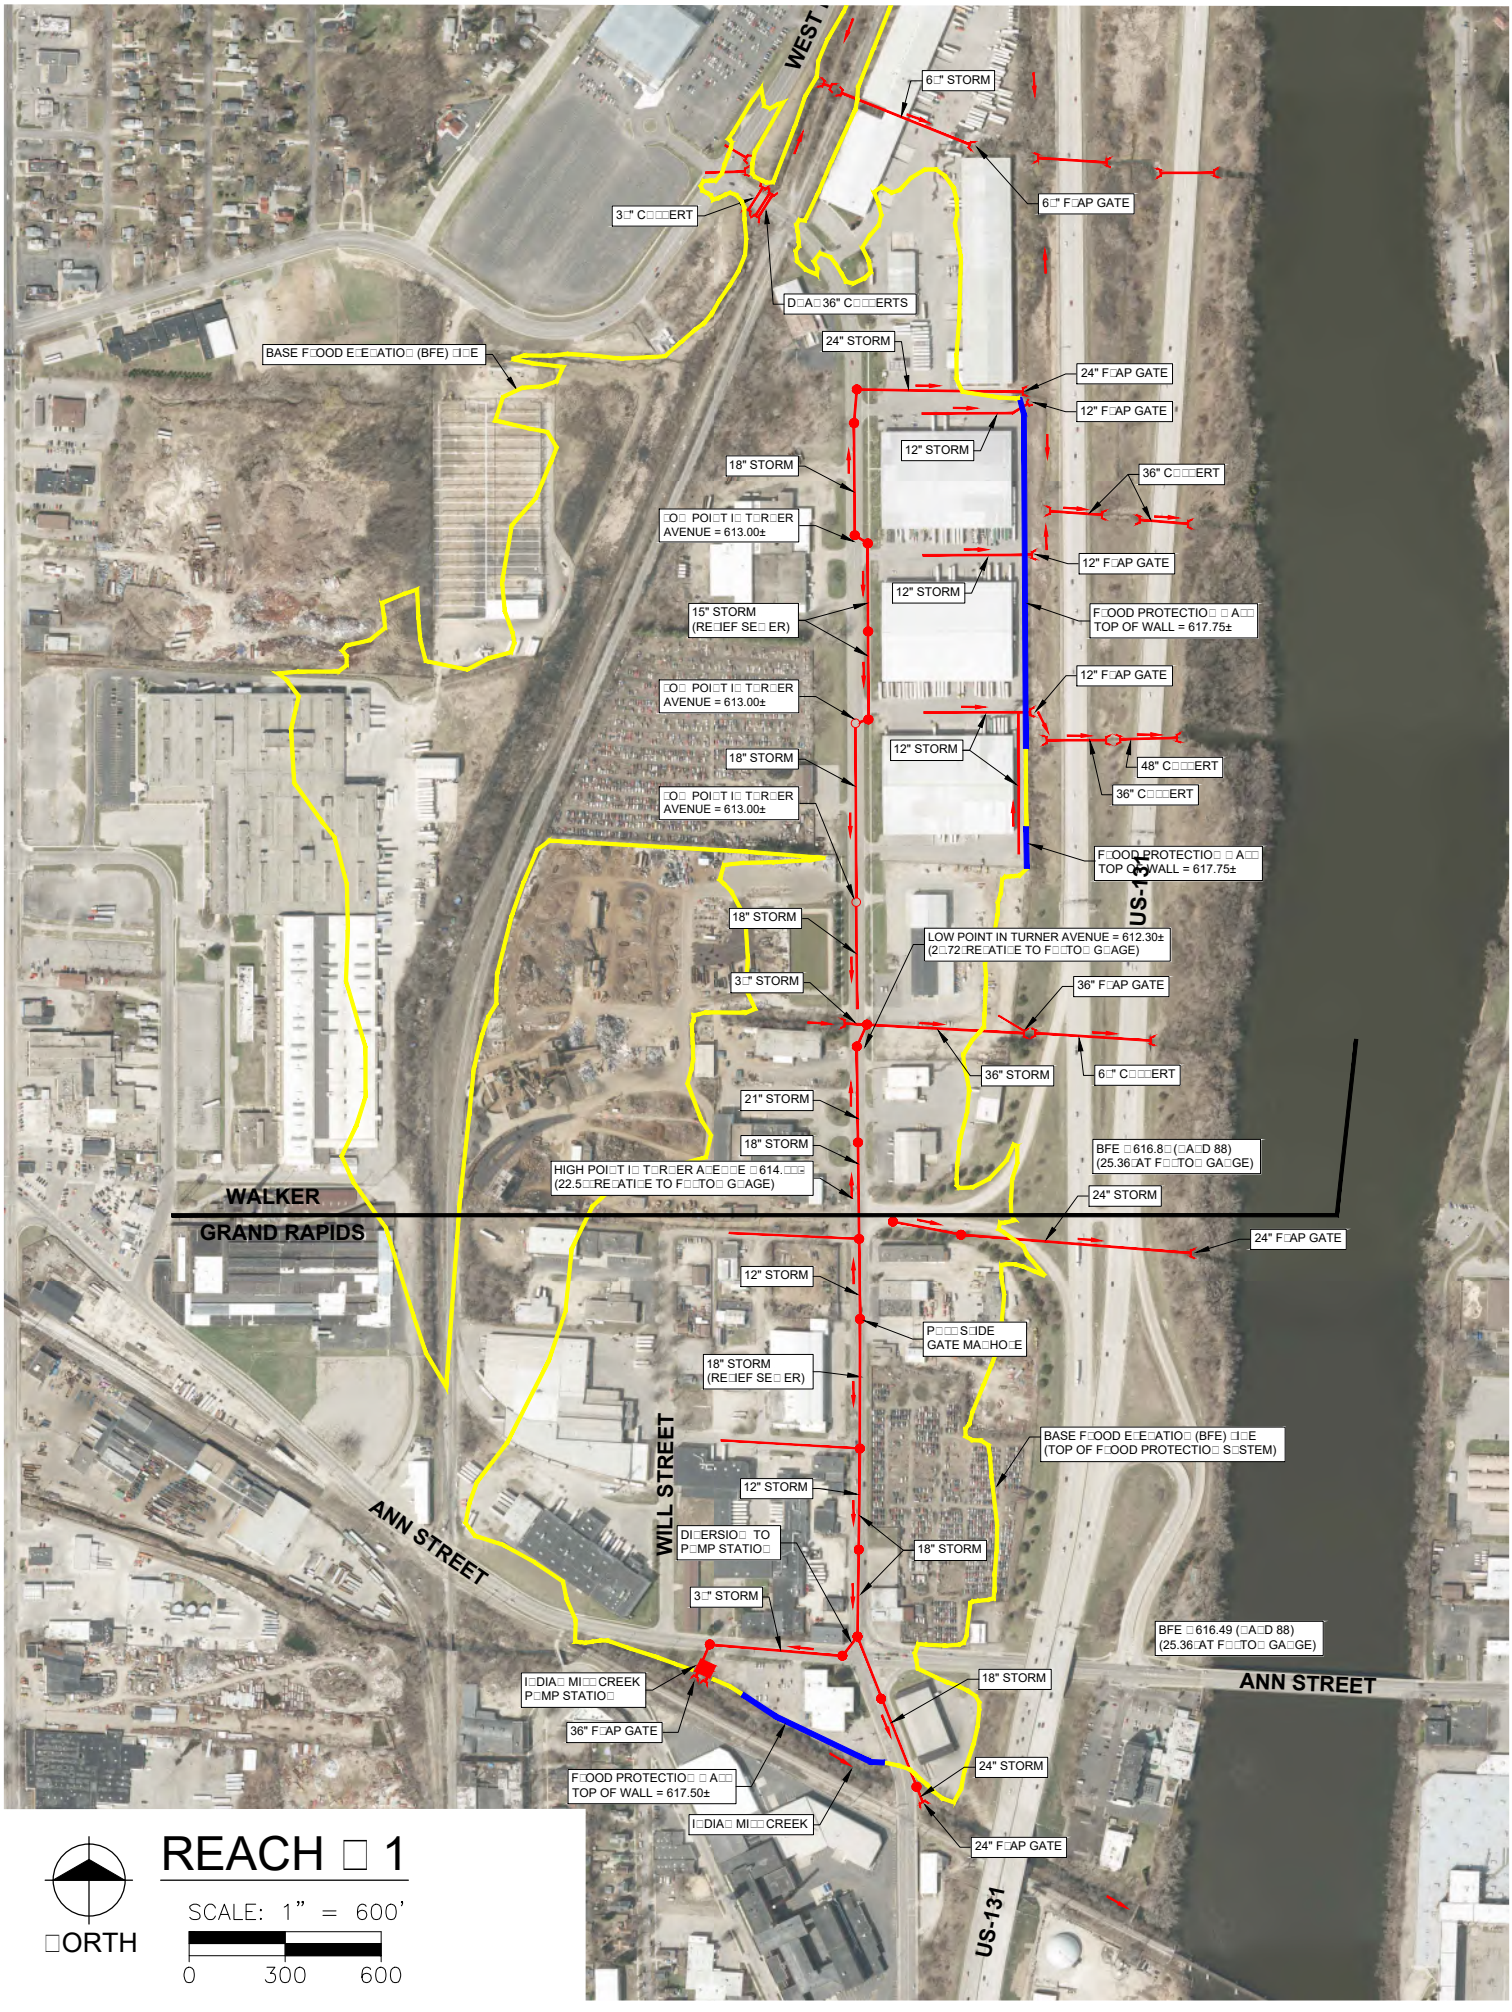
System Information

Flood Stage Information

- **Action Stage = 12.00' (603.44)**
  - Begin monitoring flood and weather forecasts; inspect flap gates.
- **Flood Stage = 18.00' (609.44)**
  - Begin preparing to close Turner Avenue.
  - For Reference: February 2017 Peak Stage = 20.67' (612.11)
- **Moderate Flood Stage = 21.00' (612.44)**
  - Turner Avenue begins to flood around catch basins 510' north of City Limits at 20.10' (611.54) *(flap gates should prevent this from happening)*
  - For Reference: April 2013 Peak Stage = 21.85' (613.29)
  - Turner Avenue flooding overflows south into the City of Grand Rapids at 22.51 (613.95) *(flap gates should prevent this from happening)*
- **Major Flood Stage = 23.00' (614.44)**
- **100-Year Flood Stage = 25.36' (616.80)(Based on 2017 FEMA Model)**
  - Levees are breached at approximately = 26.31' (617.75)
  - Major Flooding will occur.

Indian Mill Creek Storm Water Pump Station

- The Indian Mill Creek Storm Water Pump Station is located in the City of Grand Rapids. (See attached figure for location.) It serves both the City of Grand Rapids and the City of Walker.
- Interior ponding that might occur in Turner Avenue is conveyed to the pump station via a cross connection between the Grand Rapids and Walker storm water collection systems. (See attached figure)
- Should the collection system fail portions of Turner Avenue may flood up to 1 foot in depth prior to overflowing into the City of Grand Rapid overland. The flow would then entire the Grand Rapids collection system and be conveyed to the Mill Creek Storm Water Pump Station.



REACH □ 1

□ORTH

SCALE: 1" = 600'

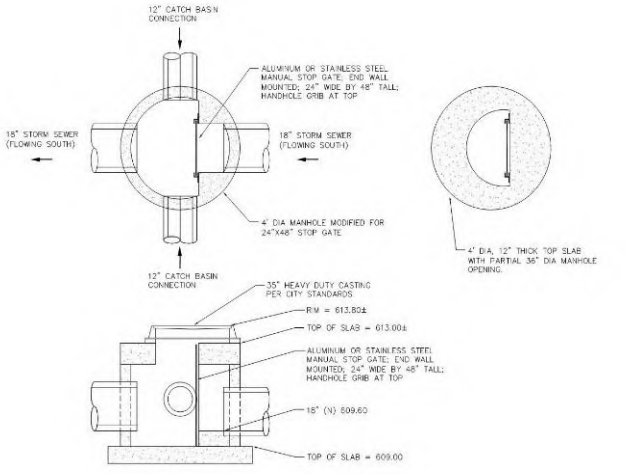
0 300 600

Overflow/Slide Gate Manhole

- 325’ south of Walker/Grand Rapids City Limits (See photo, detail and figure.)
- Rim Elevation = 613.80
- Invert of 18” Overflow Pipe to the South = 609.80

Gate Owner: City of Grand Rapids

Gate Operator: City of Walker is authorized to remove gate as deemed required to control Turner Avenue flooding.



Low Point in Turner Avenue

- 510’ north of City Limits (See photo and figure.)
- Centerline Elevation = 612.00
- Gutter Pan Elevation (west side) = 611.5 +/-
- Gutter Pan Elevation (east side) = 611.5 +/-

Other Low Points

- 980’ north of City Limits; Centerline Elevation = 613.00 (See attached figure.)
- 1,530’ north of City Limits; Centerline Elevation = 613.00 (See attached figure.)
- 2,130’ north of City Limits; Centerline Elevation = 613.10 (See attached figure.)

High Point in Turner Avenue

- At Walker/Grand Rapids City Limits (See attached figure.)
- Centerline Elevation = 614.50
- Gutter Pan Elevation (west side) = 613.95
- Above 613.95 water will flow into the City of Grand Rapids

Low Point in Walker Levee System

- 617.75 (See top of wall in picture below); equal to 26.31’ at Grand Rapids NOAA Gauge.
- Provides approximately 1 foot of freeboard above the 100-year flood elevation.

Operational Scenarios

Normal River Levels

No Rain to Moderately Heavy Rainfall Event

- Slide gate to remain in place separating City of Walker and City of Grand Rapids storm water collection systems.

Heavy Rainfall Event

- Monitor water levels in:
    - Catch basins or centerline manhole at the low point in Turner Avenue at 510' north of the City Limits.
    - Slide gate manhole at 325' south of the City Limits.
- The slide gate may be removed if the water level in the slide gate manhole is less than the water level in the catch basins and manhole at 510' north of the City Limits. The gutter pan elevation at the low catch basin is 611.5 +/-; the rim elevation of the slide gate manhole is 613.80.
- Reinstalled slide gate once any flooding in Turner Avenue has subsided and no further rain is forecasted.
- Continue to monitor water levels if additional rain is forecasted.

Action Stage (12') to Flood Stage (18')

No Rain to Moderately Heavy Rainfall Event

- Slide gate to remain in place separating City of Walker and City of Grand Rapids storm water collection systems.
- Monitor flap gates to ensure they close properly. See attached figure for flap gate locations.

Note: Even if backflow prevention fails water levels will get no higher than 609.50 in the Turner Avenue collection system. No street flooding will occur.

Heavy Rainfall Event

- Follow same procedure as for "Normal River Levels".
- Monitor flap gates to ensure they close properly. See attached figure for flap gate locations.

Stage 18' and 22.5'

Monitoring

- Monitor flap gates to ensure they have closed properly. See attached figure for flap gate locations.
- Monitor river level relative to water level in the Turner Avenue collection system. River water is leaking into the collection system, likely at one or more of the flap gates, in water levels are equal.
- If flooding occurs: Once elevation 613.95 or Stage 22.35' (if river water is entering the system) is reached flood waters will overflow the high point in Turner Avenue and flow overland into the City of Grand Rapids. Allow this to happen.

No Rain to Moderately Heavy Rainfall Event

- The slide gate does not need to be removed if river water is not leaking into the Turner Avenue collection system.
- Remove the slide gate if river water is leaking into the Turner Avenue collection system.
- Reinstalled slide gate once the risk of flooding in Turner Avenue has subsided.

Heavy Rainfall Event (Occurring or Forecasted)

- Remove slide gate regardless of whether or not river water is leaking into the Turner Avenue collection system.
- If flooding occurs: Once elevation 613.95 or Stage 22.35' (if river water is entering the system) is reached flood waters will overflow the high point in Turner Avenue and flow overland into the City of Grand Rapids. Allow this to happen.
- Street flood water will recede slowly once rainfall event has ended.
- Reinstalled slide gate after flooding in Turner Avenue has subsided.

Stage 22.5' to 26'

Same procedure as for previous scenario except if backflow prevention fails Turner Avenue will flood and overflow the high point into the City of Grand Rapids. Allow this to happen.

Stage 26' and Greater

Levee system will be breached. An area equal to or greater than the yellow boundary on the attached figure will flood. Follow previous scenario procedure.

Appendix

Appendix F

City of Walker and Kent County Emergency Management Agreement 3-27-19

CITY OF WALKER AND KENT COUNTY EMERGENCY MANAGEMENT AGREEMENT

3-27-19

I. Overview

This Emergency Management Agreement is between the City of Walker and Kent County.

The City of Walker is exercising its option to appoint the Kent County Emergency Management Coordinator as its coordinator, as provided for in Act 390, Section 9, as amended.

By this appointment, the City of Walker agrees to become part of the Kent County Emergency Management Program.

This agreement sets forth the emergency management relationship between the City of Walker and Kent County, and it is agreed both parties will act in accordance with this Agreement and with procedures set forth in the Kent County Emergency Operations Plan and the City of Walker Support Emergency Operations Plan.

II. Scope

This plan is a flexible document in which changes from the content of the plan may occur due to unique nature of emergencies. Each agency that has a supported role in this plan or its elements has developed Standard Operating Procedures (SOP) which provides systematic instructions for accomplishing assigned functions. In addition, to support emergency preparedness and response efforts, the local government also conducts other activities such as personnel training, participating in exercises, encouraging chronic disease prevention techniques; educating the public on awareness activities, and use of appropriate land use planning decisions for mitigation and prevention purposes. Through this plan, the City of Walker continues to implement the National Incident Management System, participating in efforts to provide an effective and efficient incident management operation.

III. Plan Maintenance and Implementation

The plan has been developed together with local community, and county officials to ensure consistency within the county emergency management program documents. The plan is required to be approved by Walker City Commission every year, or whenever the Mayor

changes. A copy of the updated plan is to be forwarded to the County Emergency Management Office. Upon approval, it will be implemented, tested through exercises in concurrence with County officials, and reviewed/updated to maintain currentness with the County Emergency Operations Plan.

This plan has been provided to all municipal agencies, elected officials, the county emergency management office and the MSP/EMHSD district coordinator.

A. MUNICIPAL RESPONSIBILITIES

The City of Walker agrees to be responsible for the following:

1. Appointment of Municipal Emergency Management Liaison

   A Municipal Emergency Management Liaison and one or two successors to this position will be appointment by the Mayor and/or City Manager of the City of Walker to assist the Kent County Emergency Management Coordinator in all matters pertaining to disaster prevention, mitigation, response, and recovery operations within the municipality.

   Maintain a Support Emergency Operations Plan that identifies emergency response procedures in relation to the Kent County Emergency Management Program. The Support Plan will be considered to be part of the County's Emergency Operations Plan and shall be maintained in accordance with the standards of currentness of the County's Emergency Operations Plan. The Support Plan shall contain the signature of the Mayor and City Clerk of the City of Walker and be forwarded to the County.

B. COUNTY RESPONSIBILITIES

Kent County agrees to be responsible for the following:

1. Coordinate all Emergency Management Functions

   The Kent County Emergency Management Coordinator is primarily responsible for coordinating all Emergency Management functions pertaining to disaster prevention, mitigation, response, and recovery operations within the County and municipalities that are part of the County Emergency Management Program. The Kent County Emergency Management Coordinator is responsible for all communications with the Michigan State Police, Emergency Management Division, which includes filing necessary paperwork required for funding, filing of flash reports, and developing assistance requests for the City of Walker. The Kent County Emergency Management Coordinator will continually work with the City of Walker Emergency Management Liaison when involved in emergency management activities that involve the municipality.

2. Development of Emergency Operations Plan; Support Plan Assistance

The Kent County Emergency Management Coordinator has the responsibility of developing the Kent County Emergency Operations Plan in accordance with Federal and State requirements. The Kent County Emergency Management Coordinator will assist the City of Walker Emergency Management Liaison with the development of the City of Walker Support Emergency Operations Plan to assure that it meets specified requirements and is compatible with the Kent County Emergency Operations Plan.

C. COUNTY/MUNICIPAL RESOURCES

If the City of Walker requests and receives emergency or disaster assistance from the County, in accordance with this Agreement, the County will absorb the costs. If the City of Walker provides resources to the County for emergency or disaster assistance in some other part of the County program area, the City of Walker will absorb the cost.

D. ANNUAL WORK AGREEMENT

Each year the Kent County Emergency Management Coordinator will develop an Annual Work Agreement. This Agreement will list, in priority order, Emergency Management Program items related to mitigation, preparedness, response and recovery that should be considered for that year, and shall be compatible with the annual County Work Agreement.

Approval of the EAP

Acknowledgement of Receipt and Understanding

Two copies of this acknowledgement page are included in this copy of the GRFPS EAP. The addressee of this copy of the EAP shall sign and date as indicated below to acknowledge receipt. More importantly, the addressee signifies by their signature that they have read the EAP and understand their role in making the necessary emergency contacts and, if appropriate, mobilizing the necessary personnel and equipment to protect the public in the event of a levee embankment and/or drainage structure problem at the GRFPS.

One copy of this acknowledgement form, signed and dated by the appropriate person, shall be forwarded to the City Engineer and Public Works Department at the addresses shown below. The other signed and dated copy should remain in this copy of the EAP.

Preface

The Grand River Flood Protection System (GRFPS) was constructed along the left and right banks of the Grand River to provide protection for the residents, commercial and institutional establishments, and industries of Grand Rapids, Michigan from the 100-year return interval flood. The flood protection system was constructed in segments and modified over a number of years making use of natural stream banks, floodwalls, levees, and road and railroad embankments.

This manual is compiled to assist City of Grand Rapids (City) officials in the operation, maintenance and inspection (OM&I) of the GRFPS including floodwalls, levees, stormwater pump stations (SPS), backflow prevention devices, and closure structures. The procedures described in this manual are generally for conditions in the Grand River when the stage, as measured by the U.S. Geological Survey (USGS) gage, upstream of the Fulton Street Bridge is less than 12 feet; however, this manual also provides guidance on flood preparatory measures that may be enacted when flood conditions are predicted to occur. For flood conditions where the stage is above 12 feet and predicted to rise to 18 feet or higher, refer to the GRFPS Emergency Action Plan (EAP).

The successful functioning of the GRFPS is not assured by the mere construction of an adequate system of levees, walls, gates, SPSs, etc. If the GRFPS is to function, it must be carefully maintained throughout normal river stage periods and properly operated during flood periods. Failure to do so can result in severe losses in property and life and may undermine the confidence of the citizens in their reliance on the system. The necessity for proper continuous maintenance cannot be too highly stressed. Considerable damage may be incurred through failure of a minor element of the system at flood times caused by neglect, deterioration, or damage that could have been prevented by proper maintenance. Proper maintenance and operation require that responsible local officials have a thorough understanding of the functions of the various units of the system and the knowledge of best methods of maintaining the system and operating it during flood emergencies. It is with this purpose in mind that this manual has been prepared for the guidance of those responsible for the maintenance and operation of the GRFPS.

Introduction

System Overview

The GRFPS is located along both banks of the Grand River in the City of Grand Rapids, Kent County, Michigan. A general plan of the protected area is shown on Figure 11. The GRFPS consists of a combination of protective structures built along the banks of the Grand River. These protective structures include concrete flood walls and low earth berms. The interior flood control system consists of six SPSs and the stormwater sewer system that drains to the Grand River, Indian Mill Creek, and Plaster Creek. Under non-flood conditions in the Grand River, stormwater discharges directly to the river through pipe penetrations through the floodwalls and storm drains installed in the natural stream banks. In the event that flood stages in the river are high enough to close the backflow devices on the stormwater drain outlets, the stormwater flow is diverted to the SPSs. The GRFPS was designed to protect approximately 1,420 acres on the right (west) bank and 195 acres on the left (east) bank of residential, commercial, institutional, and industrial properties within the City boundaries from the 100-year flood. The GRFPS also provides pumping capacities, stormwater interceptors, and gravity outfalls to discharge interior runoff during a rainfall event.

Construction History

A floodwall was constructed along the Grand River in Grand Rapids as early as 1899 to protect the City lighting plant and crematoria. Following the flood of record in March 1904, and another flood in June 1905, the City funded construction of flood walls including a wall that extended from a point 3/4 mile north of Leonard Street to the south end of Market Avenue on the east side of the river and from north of Leonard Street to the Wealthy Street Bridge on the west side. This construction occurred in the period 1907 through 1910. Over the years since then, a variety of floodwalls, earth berms, stormwater collection systems, SPSs, and backflow prevention measures have been constructed along both banks of the Grand River within the City limits. Recent floodwall improvements were made in the period 1998 to 2008, in accordance with the recommendations of the Grand River Floodwall Implementation Plan (1995).

Regulations

Floodplain management regulations are codified in the Code of the City, Title II—Utilities and Services, Chapter 32—City Stormwater Drainage System, Article 6. Floodplain Standards and Title V—Zoning and Planning, Chapter 61—Zoning Ordinance, Section 5.8.05 Flood Plain Overlay District (OD-FP).

Procedures

Purpose

The successful functioning of the GRFPS can be assured by following the procedures set forth in this manual. By doing so, all of the benefits and protection against floods for which the GRFPS were designed can be secured.

Proper OM&I require that responsible local officials have a thorough understanding of the functions of the various units of the flood protection system; the best methods of maintaining them during normal river stages; and of operating them during flood emergencies. It is with this purpose in mind that this manual has been prepared for the guidance of the City in the OM&I of the GRFPS. This manual assembles and correlates all the details essential for satisfactory OM&I of the flood protection system, so maximum flood protection may be available at all times during the service life of each component of the entire asset.

Duties of the Superintendent

The Superintendent of the flood protection system should be the City Environmental Services Department Manager and designated members of his/her support staff. The duties of the Superintendent should include the OM&I oversight, records keeping, and correspondence with the other City officials and departments. The Superintendent should have available the names, addresses, and telephone numbers of all key personnel, and a reasonable number of substitutes. The key personnel should have similar information on all of the persons that will be required for assistance in the discharge of their duties. These persons should include the following:

- An assistant to act in the Superintendent's place in cases of his/her absence or indisposition.
- Supervisors in sufficient number to lead maintenance, operation and inspection of the GRFPS. High qualities of leadership and responsibility are necessary for these positions.
- Persons knowledgeable in the manual operation of each SPS in the event that the Supervisory Control and Data Acquisition (SCADA) system becomes inoperable.

The Superintendent should ascertain that all of his key persons have read the portions of the OM&I Manual pertaining to their duties. He/she should also see that copies of the Stormwater Pump Station (SPS) operating instructions and drawings are posted in the operating room of each station, and that they are preserved in a legible condition.

The Superintendent should be responsible for the development of an organization capable of providing for the efficient OM&I of the GRFPS, and the necessary maintenance of the entire asset during normal stages of the river.

The provisions of this manual include general requirements that cover practically all types of local flood protection works. They are supplemented by technical data and instructions pertinent to the GRFPS which are necessary for its efficient OM&I.

OM&I Management

The general requirements for the OM&I management of the GRFPS are as follows:

- The structures and facilities should be continually maintained as necessary to obtain the maximum benefits.
- The Superintendent shall be responsible for the efficient OM&I of all the structures and facilities and for routine inspection and maintenance of the entire asset.
- A reserve supply of materials needed during a flood emergency should be kept on hand at all times.
- No encroachment or trespass which will adversely affect the efficient operation or maintenance of the GRFPS should be permitted upon the rights-of-way for the GRFPS.
- No improvement or construction shall be permitted within the limits of the GRFPS right-of-way, nor should any change be made in any feature of the GRFPS without prior determination by the City Engineer that such

improvement, construction, or alteration will not adversely affect the functioning of the GRFPS. Such improvements or alterations, as may be found to be desirable and permissible under the above determination, should be constructed in accordance with standard engineering practice. Record drawings or prints showing such improvements or alterations as finally constructed should be furnished to the City Engineer after completion of the work.

- At no time should the level of flood protection provided by the GRFPS during construction or any alterations, including excavation, of improvements that pass over, under, or through the GRFPS, be less than that provided for a 100-year flood (1% annual chance of occurrence). All temporary or permanent flood prevention measures made to the GRFPS to facilitate construction must be approved by the City Engineer.
- The City Engineer and the Superintendent or authorized representatives should have access at all times to all portions of the GRFPS.
- Maintenance measures or repairs which the City Engineer, the Superintendent, or their authorized representatives deem necessary, should be coordinated with the Asset Management Plans for the components of the GRFPS. The Asset Management Plans shall be used as the guides for ongoing maintenance and improvements to the GRFPS.

Permits for Use of Rights-of-Way

The rights-of-way for the GRFPS have been procured and protective works have been constructed thereon for the protection of life and property in times of flood. The Office of the City Engineer provides for the legitimate use of the rights-of-way in addition to crossing by gas lines, oil lines, and utilities, or other use of a similar nature.

A permit from the Michigan Department of Environment, Great Lakes, and Energy (EGLE) may be required for construction along or modifications to the flood protection system under Part 301, Inland Lakes and Streams, of the Natural Resources and Environmental Protection Act (NREPA), 1994 PA 451, as amended. The routine OM&I of the GRFPS is the responsibility of the Environmental Services Department, and will be completed in accordance with this manual. The right-of-way for the GRFPS is issued, recorded, and maintained in document form by the Office of the City Engineer.

Adjacent Construction by Others

When owners of properties adjacent to the levees and/or floodwalls initiate new construction, particularly if it involves deep excavation, the City Engineer should be notified and take such action as may be necessary to assure that there is no encroachment on right-of-way, that adequate shoring is used to prevent disturbing flood protection foundations, and that the work insofar as possible is performed outside of flood periods.

River Stage Prediction

It is the responsibility of the City Engineer to keep advised of predicted river stages. This information will enable the City Engineer to make all the necessary preparations required for the operation and erection of those features of the system for the protection of the areas against high river stages in advance of their occurrence.

The river stages referred to herein correspond to automated gage readings taken at the USGS Station 04119000, Grand River at Grand Rapids, Michigan. The gage station is located at latitude 42˚ 57’ 52”, longitude 85˚ 40’ 35” referenced to North American Datum of 1927, in NE 1/4 Section 25, Township 7 N, Range 12 W, Kent County, Michigan, on the right (west) river bank, 500-feet upstream from the Fulton Street bridge in Grand Rapids and 1.7 miles upstream from Plaster Creek. The datum for the gage is 585.70-feet National Geodetic Vertical Datum of 1929 (NGVD 29) (elevation 585.25-feet North American Vertical Datum of 1988 [NAVD 88]). Current river stage information can be obtained from the National Weather Service (NWS) Forecast Office, Grand Rapids, Michigan, Advanced Hydrologic Prediction Service at: http://water.weather.gov/ahps2/hydrograph.php?wfo=grr&gage=gdrm4 or the USGS Michigan Water Science Center at: http://waterdata.usgs.gov/mi/nwis/sw

The predicted stages are available for up to five days in advance. This is sufficient time to allow the City Engineer to make all necessary emergency preparations and conduct such operations as may be required for various river stages as described in this manual and the National Incident Management System (NIMS). It should be kept in mind that the predicted stage is only an approximation and may possibly range higher.

Procedure at Various River Stages

Appendix 4 lists the operations to be performed at various river stages.

The actual time of mobilization of the various personnel will be dependent upon the rate of rise of the Grand River (see "Grand River – Rate of Rise – Closure Operation" in Emergency Closure Structures), the various functions to be performed, the condition of the flood protection system, the time required to erect sandbag and other closures, and other pertinent requirements of the Special Operation & Maintenance During High Water Periods section of this manual.

Reference Drawings

A list of reference drawings including record drawings is included in Appendix 1. The station references used in this manual are referenced to a survey baseline along the centerline of the Grand River that begins at Station (Sta.) 2003+05.20, at the right lane edge of pavement on the east bound lanes of the Interstate 196 (I-196) bridge. The survey baseline station numbers increase in the upstream direction.

Elevations

The GRFPS was constructed at different times under different construction contracts. Therefore, different vertical datum were used throughout the history of construction. To the extent possible, this manual attempts to identify the elevation datum for all elevations used in its paragraphs. The user of this manual should be careful to discern which vertical datum is being used when comparing to published flood elevations. The conversion between elevations using the NAVD 88 and those using NGVD 29 is given by:

NAVD 88 = NGVD 29 – 0.4495 feet

Safety

The Superintendent should provide a health and safety plan in accordance with the Occupational Safety and Health Administration law and regulations for all personnel involved in the maintenance of the GRFPS. The Superintendent and maintenance personnel should familiarize themselves with the safety procedures and implement them during routine maintenance and flood operations. Safety precautions should be complied with as follows:

- Personnel should remain alert to the possibility of hazardous gases at the structures, primarily at the pumping stations, manholes, and junction chambers, and take appropriate safety measures when inspecting, maintaining, or operating the structures. Sewer gases and pungent vapors may accumulate in the pump chambers. Power ventilation should be accomplished before any attempt is made to enter the pump chambers.
- Two persons should always be present during maintenance, inspection, or operation of all drainage structures. The buddy system should be used to provide necessary help and assistance to each other in the event an accident occurs. At no time should one person be allowed to enter the pump chamber area without an assistant standing by on the operating floor. A lockout/tagout procedure shall be required.
- Since a potential drowning hazard exists during flood emergencies, emergency response teams from the City's Fire Department with appropriate personnel and equipment shall respond accordingly.

Inspections

Annual inspections of the GRFPS will be completed by the Office of the City Engineer, or their consultants, in accordance with the Asset Management program. The Environmental Services Department will also conduct routine inspections of the GRFPS during the course of the year. Repair and maintenance of the GRFPS should be coordinated with the scheduled Asset Management improvements when possible. Other maintenance activities that should be completed as soon as possible are completed in cooperation with the City Engineer.

Earth Embankments (LEVEES)

Earth Embankment Maintenance

The pertinent requirements for maintenance of the earth embankments are as follows:

The Environmental Services Department shall provide at all times such maintenance as may be required to insure serviceability of the earth embankments in time of flood. Measures should be taken to promote the growth of sod, exterminate or remove burrowing animals, and to provide for routine mowing of the grass and weeds, removal of wild growth and drift deposits, and repair of damage caused by erosion or other forces. Where practicable, measures should be taken to retard bank erosion by placement of riprap stone or by planting suitable plants on areas riverward of the levees. Inspection of the earth embankment should be completed by the Environmental Services Department to insure the above maintenance measures are being effectively carried out and to be certain that:

- No unusual settlement, sloughing, or material loss of grade or earth embankment cross section has taken place.
- No caving has occurred on either the land side or the river side of the earth embankment which might affect the stability of the earth embankment section.
- No seepage, saturated areas, or sand boils are occurring.
- Toe drainage systems are in good working condition and that such facilities are not becoming clogged.
- Drains through the earth embankments and backflow gates on said drains are in good working condition.
- No revetment work or riprap has been displaced, washed out, or removed.
- No action is being taken, such as burning grass and weeds during inappropriate seasons, which will retard or destroy the growth of sod.
- Access roads to and on the earth embankments are being properly maintained.
- Crown of the earth embankment is shaped to drain readily and roadway, if any, is well shaped and maintained.
- There is no unauthorized vehicular traffic on the earth embankment.
- Encroachments are not being made on the earth embankment right-of-way which might endanger the structure or hinder its proper and efficient functioning during times of emergency.

Burrowing Animals

Burrowing animals (muskrats and groundhogs) create seepage paths in earth embankments. Burrowing animals should be removed from the earth embankment and the burrows filled with a mud-pack prepared by adding water to a 90 percent soil and 10 percent cement mixture until a slurry or thin cement consistency is attained. After filling the burrow with the mud pack mixture, the burrow entrance should be filled with dry earth and seeded.

Drift

Drift (river-borne debris) should be removed from the earth embankment and other grassed areas on the right-of-way at the end of each winter flood season before the new growth of grass starts in the spring, and after each flood occurring during the growing season.

Gullies, Holes, and Washes

Gullies, holes, and washes in the levee, slopes, and berms should be repaired using compacted clay soils in an approved manner.

Earth Embankments Crest Depressions

Gaps occurring where trail or road crossings have been worn down or where the earth embankment may be below grade should be remedied. It is advisable to run levels occasionally to determine whether depressions have occurred in the top of the earth embankment. The profile of the top of the earth embankment should be maintained to the elevations shown on the construction plans.

Spare Cover Vegetation

All areas deficient in sod should be reseeded or resodded.

Seeding

When new permanent seeding is necessary to obtain cover for bare areas, it is recommended that such work be done in the late summer, between July 15 and September 15, or in the spring between April 10 and June 5. Temporary seeding can be performed up to a month before or a month after the above dates, respectively; however, temporary seeding must be followed-up with permanent seeding during the appropriate season.

Sodding

Where sodding is considered the most favorable method of reestablishing a good stand of grass on the earth embankment, it should be performed in advance of the flood season to ensure knitting of the transplanted sod with the prepared base. Sodding should preferably be done between May 1 and October 20, if irrigation can be provided as needed. Sod should not be laid between June 10 and September 10 without irrigation.

Grass Mowing

Grass should be mowed as necessary to help maintain a good stand of grass.

Earth Embankment (Levee) Inspection

Sample check list forms for use in performing inspections of earth embankments (levees) are enclosed as Appendix 2.

Earth Embankment (Levee) Operation

When the Grand River flood stage exceeds 12 feet at the USGS gauge station, the earth embankment should be patrolled daily, or more frequently as conditions warrant, to locate possible sand boils or unusual wetness of the landward slope and to be certain that:

- There are no indications of slides or sloughs developing.
- Wave wash or scouring action is not occurring.
- No low reaches of earth embankment exist that may be overtopped.
- No other conditions exist which might endanger the structure as determined by the City Engineer.

Earth Embankment Damage Due to High Water:

If it is found that sand boils, scouring, or other hazardous conditions are occurring, immediate steps should be taken to control the situation and repair or correct any damage. In the face of such dangerous conditions due to high water, the provisions of the NIMS and city-wide Asset Management Plan shall be implemented. Suggested methods of operations for combating such flood conditions are given in the Special Operation & Maintenance During High Water Periods section of this manual.

Sand Boils and Seepage Areas:

When sand boils or other seepage areas are observed which are of small magnitude, posing no major threat to structure safety, and therefore are not economically feasible to repair, their locations should be recorded for future action in conjunction with Asset Management improvements.

Flood Walls

Flood Wall Maintenance

The City Engineer, in accordance with the GRFPS Asset Management Plans, should provide such maintenance strategies as may be required to ensure a continued high level of serviceability of the entire asset in time of flood conditions. Measures should be taken to repair concrete cracks, spalls, and cavities; prevent leakage through concrete joints, remove trees and brush at the base of the flood walls and in joints, cracks, or cavities in the concrete; remove drift deposits at the base of the wall; remove materials deposited or stored along the inside surface of the wall; and repair damage caused by erosion, floating ice and debris impact, or other forces. Where practicable, measures should be taken to retard bank erosion at the base of the flood wall by placement of riprap stone or by planting suitable plants on areas riverward of the flood wall.

Annual inspections should be made by the Office of the City Engineer in accordance with the flood protection system Asset Management Plans. The Superintendent shall also visually observe the GRFPS on a periodic basis and review with the City Engineer if repairs are necessary to maintain operational soundness of the floodwalls. The visual observations shall verify that the above maintenance measures are being effectively carried out and, be certain that:

- All joints contain water stops or a mastic compound for the full height of the wall to prevent leakage during a flood.
- Cracks, spalling, chips, and cavities in the wall concrete and caps are not extensive or deep enough to endanger the stability of the wall.
- Flood wall monoliths are aligned.
- Flood wall monoliths have not settled.
- Flood wall caps are intact and not providing a gap for flood waters to overflow.
- No appurtenances are attached to the river side of the wall that could overstress the wall concrete and reinforcement or catch debris during a flood.
- No animal burrows are present along the river-side toe of the wall that may provide a seepage path under the wall.
- Any sand boil locations are monitored and controlled during a flood and promptly addressed after the flood waters recede.
- No seepage, saturated area, and/or boils are occurring.
- No undue settlement has occurred which affects the stability of the wall or its water tightness.
- No trees exist, the roots of which might extend under the wall, and offer accelerated seepage paths.
- There are no encroachments upon the right-of-way, which might endanger the structure or hinder its functioning in time of flood.

Care is being exercised to prevent accumulation of debris adjacent to walls.

No bank caving conditions exist riverward of the wall which might endanger its stability.

Toe drainage systems are in good working condition and not becoming clogged.

Sample inspection check list forms for use in making inspections of the flood walls are shown as Appendix 2.

Flood Wall Repairs

Repairs to floodwalls or other concrete structures should be completed in conjunction with the Asset Management Plan improvements, when possible, with approval of the City Engineer. Repairs that require immediate attention should be completed through cooperation between the Supervisor and the City Engineer.

Adjacent Land Maintenance

Maintenance of the land area adjacent to the flood walls should comply with Part III of this manual.

Flood Wall Operation

Daily inspection (or more frequently if conditions warrant) of the floodwalls, by the office of the City Engineer, should be maintained during flood warning (Emergency) conditions (stage > 18 feet), to locate possible leakage at monolith joints or seepage underneath the wall. Should it become necessary during a flood emergency to pass anchor cables over the wall, adequate measures should be taken to protect the concrete and construction joints. Immediate steps should be taken to correct any condition with endangers the stability of the wall.

Adjacent Land Damage Due to High Water

If it is found that seepage, saturated areas, sand boils, bank caving, or other situations detrimental to wall stability are occurring during flood watch (Non-Emergency) or warning (Emergency) conditions (stage > 12 feet), emergency repairs as described in Appendix 3 of this manual should be employed immediately.

Drainage Structures

Maintenance

Under the classification of drainage structures include: culverts, seepage and toe drainage systems, manholes, storm sewers, SPS discharge lines that pass through, under, or over the levee and floodwalls, and flap and sluice gates. The various backflow prevention measures on the pipe penetrations through the GRFPS with outfalls below the Base Flood Elevation (BFE) are described in detail in the Closure Analysis Report.

Adequate measures should be taken to ensure that inlet and outlet channels are kept open and that trash, or debris is not allowed to accumulate near drainage structures. Flap gates and manually operated gates and valves on drainage structures should be examined, lubricated, and operated annually. Periodic inspections should be made by the Superintendent to be certain that:

- Pipes, gates, operating mechanisms, riprap, and headwalls are in good conditions.
- Inlet and outlet channels are open.
- Care is being exercised to prevent the accumulation of trash and debris near the structures, and that no fires are being built near bituminous coated pipes.
- Erosion is not occurring adjacent to the structure which might endanger its water tightness or stability.

Immediate steps will be taken to repair damage, replace missing or broken parts, or remedy adverse conditions disclosed by such inspections, unless it can be delayed to be included with future Asset Management improvement projects.

Sluice Gates: Sluice gates are located in the SPSs and in several storm and combined sewer gate chambers. These gates should be trial operated, serviced, and lubricated annually. The gate slides and stems should be well greased. Sluice gate cranks for manual operation are kept in the nearest SPS.

Flap Gates and Duckbill Gates: Flap gates are installed on the ends of the discharge lines of the pumping units in the following SPSs:

- Market Avenue SPS (River Station 2074+00)
- Wealthy Street SPS (River Station 2068+00)
- Front Avenue & Scribner Avenue SPS (River Station 2155+00)
- Indian Mill Creek SPS (Indian Mill Creek River Station 16+50 above confluence with Grand River)
- Caledonia Street SPS (River Station 2214+50)
- Palmer Street SPS (River Station 2235+00)

In addition, there are flap gates or duckbill gates on the outlets of the storm drains and in manholes at the locations listed in Tables 1A, 1B, and 1C. Note that all of the gates in the following tables are flap gates unless otherwise noted.

Table 1A - East Side of Grand River

**River stations measured in the upstream direction from the confluence with the Grand River.

The flap gates should be operated, serviced, and lubricated annually to be certain that they swing freely and do not bind. Clear all debris that prevents full closing of the flap gate. Caution: In order to prevent possible damage, do not allow the flaps to slam against their seats.

Inspection

Drainage structures should be inspected annually. Sample inspection check list forms are provided in Appendix 2.

Operation

Whenever a flood stage exceeding 18 feet as measured at the USGS Station 04119000, Grand River at Grand Rapids, Michigan, is predicted by the NWS Forecast Office, Advanced Hydrologic Prediction Service (see Permits for Use of Rights-of-Way section), all gates should be inspected before water reaches the invert of the pipe and any object which might prevent closure of the gate should be removed. Manually operated gates and valves should be closed as necessary to prevent inflow of flood water. All drainage structures in earth embankments (levees) should be inspected frequently during floods to ascertain whether seepage is taking place along the lines of their contact with the embankment. Immediate steps should be taken to correct any adverse condition.

Sluice and Flap Gate Operation Caution

Observe cautions for opening and closing the sluice gates and operating the flap gates as directed in the maintenance instructions.

Flap Gate and Duckbill Gate Operation

The flap gates and duckbill gates should be inspected in order that objects that would prevent the gate from seating properly or sealing may be removed. The flap gates and duckbill gates should be closely monitored until it is definitely determined that they are securely closed and that no more debris will pass through their outlets. Water will pass through a flap gate and a duckbill gate outlet as long as the landside water surface is above the riverside water surface. Until both surfaces are above the crown of the pipe, floating debris and trash will attempt to pass through the drainage structure and can possibly keep the gate from seating properly when the water on the riverside reaches an elevation above that on the landside.

Emergency Closure Structures

Maintenance

Three small pipe penetrations, one sidewalk penetration, and one railroad penetration through the flood wall are not protected from the base flood elevation by the permanent GRFPS. Emergency temporary closures consist of either sewer plugs or prefabricated metal closures. Each closure, including storage and hauling information, is listed in the table in Appendix 4. The City of Grand Rapids Environmental Service Department is responsible for the storage, maintenance, inspection and installation of all closure devices.

The sewer plugs and other closures should be inspected annually to be certain that:

- Proper closure can be made promptly when necessary (no obstructions are found in the area where the closure would be installed that would obstruct installation).
- Sufficient materials are on hand for the erection of other closures (e.g. sandbags, lumber, wire, etc.) and that the location of such materials will be readily accessible in times of emergency.
- Closures are in good condition.
- Sewer plugs are clean and free of leaks, bulges, cracks, or other damage that would prevent proper installation.

Inspection

The closures and sewer plugs should be inspected annually. Sample inspection check list forms are provided in Appendix 2. The forms contain an inventory of materials necessary for the complete erection and operation of the closures. All materials should be checked against the check list to ascertain their presence at the City storage location. It is advisable to check the material storage areas immediately before impending high water to see that no materials are missing. Any irregularities observed during inspections should be noted and immediate measures taken to correct them.

Operation

The closing of flow paths for flood waters should be started in sufficient time to permit full closure before flood waters flow into the protected areas. The order of operations to close flood paths is provided in the table in Appendix 4. The sewer plugs and other closures will be inspected frequently during flood periods to ascertain that no undue leaking is occurring and that drains provided to care for ordinary leakage are functioning properly.

Closures and Sewer Plugs

The sewer plugs and other closures should be made as instructed in the Special Operation & Maintenance During High Water Periods section of this manual. The installation of sewer plugs requires experienced crews with portable air compressors and pneumatic hoses.

Grand River - Rate of Rise - Closure Operation

It is imperative that ample time be allowed to install the sewer plugs and other closures before the water reaches the predicted flood elevation. It is the responsibility of the Superintendent to keep advised of predicted river stages and of possible additional local rainfall. This information will enable the Superintendent to make all the necessary preparations required for the erection of those features of the system for the protection of the area against high river stages in advance of their occurrence. River stage predictions for the Grand River and forecasts of local rainfall are issued by the NWS, Advanced Hydrologic Prediction Service, NOAA, Grand Rapids Michigan, at the internet web site: http://water.weather.gov/ahps2/hydrograph.php?wfo=grr&gage=gdrm4

With this information, it will be possible to perform such operations as may be required for various stages. The predicted stages are usually available five days in advance. This is sufficient time to allow the Superintendent to make all necessary emergency preparations. Due consideration must be given to the rate of rise of the river. Table 2 contains Rates of Rise in feet per hour for various gage readings up to flood crest of major flood experiences. By comparing a predicted flood with records of past floods (Table 2), it is possible to estimate and use as a guide Rates of Rise to be expected at various gage readings over the period required to effect closure. There are many factors determining the Rates of Rise, and the City Engineer shall be consulted in understanding the predictability of the Grand River and the Rates of Rise that may be anticipated. The period required to erect each closure must also consider the possible delays because of inexperienced help and other delays.

Table 2 - Grand River - Rates of Rise in Feet Per Hour, Grand Rapids, Michigan

Gage Readings (Zero of Gage = 585.7 feet)	April 2013 Flood	Mar. 1985 Flood	May 2004 Flood	Oct. 1986 Flood	April 1960 Flood

Gage Readings (Zero of Gage = 585.7 feet)	April 2013 Flood	Mar. 1985 Flood	May 2004 Flood	Oct. 1986 Flood	April 1960 Flood
Crest Stage	21.85	19.64	19.54	19.25	19.25
NOTES:					
(1) Action stage - River is bank full upstream and downstream of floodwalls in downtown Grand Rapids.					

Clean Up

Upon final recession of flood waters, the closures should be disassembled. All closures should be inspected, repaired or replaced, as required, and restored to appropriate storage locations. Sewer plugs should be deflated, removed from the pipes, and inspected for damage and leaks. All damaged and unsalvageable materials should be removed and disposed.

Stormwater Pump Stations

General

There are six flood pumping stations that pump stormwater that cannot flow by gravity to the Grand River or Indian Creek from the area protected by the earth embankments (levees) and floodwalls during an extreme flood. All the SPSs are inoperative when the Grand River and Indian Creek are not at flood stage. The pumping stations are placed into operation when water levels in the receiving waters are above normal to the point where pumping is required. When these conditions are reached, float-operated switches and/or transducers in each SPS initiate pump operation. Individual control panel lights for each pump are located in the SPS control centers to alert City personnel that pumps are operating and to identify possible operation problems.

This section of the manual is intended as a guide for the personnel responsible for inspection, operation, and preventative maintenance of SPS equipment. It outlines basic maintenance procedures that are in facilities of this nature in order to guide the operating personnel in systematically detecting and correcting potential defects before they develop into major failures. This section of the manual is not intended to take the place of the manufacturer's instructions on maintenance, but is a compilation of general procedures advocated by manufacturers and based upon experience. Although some manufacturers' instruction books have been furnished to the local operating agency, the Superintendent should procure and maintain for reference a manufacturer's instruction file on all equipment installed. In cases of variance within the manufacturer's instructions, the manufacturer's instructions should be followed.

Basic Equipment Care

Preventive maintenance is the systematic inspection and servicing of equipment required to assure that it remains ready to be placed into service when needed. It includes proper care, use, operation, inspection of equipment, cleaning, and lubrication. The following sections describe the basic operations making up preventive maintenance.

Inspection, Tests, and Maintenance

SPSs should be inspected by the Superintendent annually to ensure that all equipment is functioning properly so that it can be placed into operation when needed. At regularly scheduled intervals, measures should be implemented to provide for cleaning buildings and equipment, repainting as necessary, lubricating equipment as recommended by the equipment manufacturer's OM&I Manual, and verifying the operability of flash lights or lanterns for emergency lighting. Telephone service should be maintained at the SPSs to ensure that communications with the Superintendent and maintenance personnel can be maintained should the pumps require manual operation. All equipment, including switch gear, transformers, motors, pumps, valves, and gates should be trial operated at least annually. Pumps should be "bumped" on an every-other-week basis. A record should be kept showing the results of such tests.

All the SPSs receive primary electrical power from the Consumers Energy Company electrical grid. For the Wealthy Street and Front Avenue & Scribner Avenue SPSs, there are two primary electrical power lines providing power to each SPS control building. At each of these SPSs, the switch gear should be manually operated annually to isolate one of the power lines to ensure the uninterrupted flow of power to the pump controls from the other power line and then this procedure should be reversed to isolate the other power line.

The Market Avenue, Caledonia Street, Palmer Street, and Indian Mill Creek SPSs have receptacles on the outside of the SPS building to connect with mobile auxiliary power units for supplemental power. A mobile auxiliary power unit should be connected to each of the SPSs annually, started, and allowed to run for sufficient time as may be necessary to ensure their serviceability in time of emergency.

Regular inspections, tests, and maintenance of the SPSs should be accomplished as directed herein to provide a reasonable indication of the readiness of the pumping facilities for uninterrupted operation, to detect and correct mechanical and electrical defects or conditions which prevent efficient operation, and to reduce the possibility of failure of vital electrical and mechanical equipment during critical flood periods. The thoroughness and care with which the inspector performs his work has a direct effect on the readiness of the stations and can be a significant factor in reducing malfunctions and equipment failures during times of flooding. Inspections and repairs should be entrusted only to competent personnel familiar with the manufacturer's instructions in both the function and adjustment of the various devices. Operating personnel for the City should be present during any tests conducted by inspector(s). The inspector should have a general understanding of the electrical and mechanical characteristics of the equipment being inspected, and sufficient information concerning its correct operating performance to enable them to know whether adjustments and repairs are necessary. The inspector should have access to or obtain such instruction books (manufacturer's and other publications) pertaining to the equipment requiring inspection, as may be necessary for the satisfactory performance of their duties. In order to facilitate thorough inspection of the SPSs, the check lists in Appendix 2 should be used. It should be noted that the best method of maintaining mechanical and electrical equipment is trial operation and testing of the equipment at frequent intervals. It is recommended that electrical and mechanical equipment other than pumps and motors be operated in the "test position," as described by the manufacturer, as frequently as necessary so that all moving parts will operate freely at all times. Operation in the "test position" does not require operation of the motors. Any equipment removed from the station for repair or replacement should be returned or replaced as soon as practicable and should be trial operated after reinstallation. Repairs requiring removal of equipment from the station should be made during off-flood seasons whenever practical.

Manufacturer's Instructions

The general instructions cover normal operation and maintenance of the pumping equipment. The operator should also be familiar with the equipment manufacturers' drawings, literature, and instructions when detailed information may be required for OM&I (see Appendix 1). In case of major operating difficulties or repairs on a particular item of equipment, the manufacturers should be consulted.

SPS Structures

The SPS structures should be properly maintained. All doors and all metal and wood parts should be adequately protected with paint to prevent corrosion. All hardware should be well oiled or greased for ease of movement and to prevent corrosion. Any cracks or leaks that may develop in the walls, roof, or floor, allowing water to leak or seep into the structure, should be sealed with a waterproofing material. The lighting system should be maintained in good working order and all defective lamps should be replaced promptly. The stations should be kept locked when not in use and should be made inaccessible to trespassers at all times. The stations should be kept free of fire hazards.

Keys

City personnel under the direction of the Superintendent have the necessary keys for SPS access. A second set of keys is also kept at the City Water Resource Recovery Facility (WRRF).

Access Roads

The roads leading to the SPS structures from City streets should be maintained in good condition at all times. Drainage and surface repairs should receive immediate attention when conditions requiring remedial measures arise. This will ensure access to heavy rolling equipment at any time and under all weather conditions.

Trash Rack, Bar Screens, and Sluice Gates

All trash racks, bar screens, and sluice gates should be inspected annually and/or after the associated SPS has been in operation. All of the SPS trash racks are permanently mounted and require manual cleaning.

Automatic Flap Gates

The outlet ends of the pump discharge pipes in SPSs are equipped with automatic flap gates located either in the discharge well (Market Avenue, Front Avenue & Scribner Avenue, Indian Mill Creek, Caledonia Street, Palmer Street), or mounted on a headwall at the outfall structure (Wealthy Street). These gates should be maintained and operated as instructed in Appendix 1 of this manual.

Electrical Power Supply

All electrical equipment, including power lines, transformers, generators, all component parts of the power supply, the switchgear, circuit breakers, automatic controls, cutouts, insulators, switches, meters, etc., should be checked during annual inspections to assure that these facilities are in satisfactory operating condition and ready for service. The depth monitoring equipment is described below.

The power lines and appurtenances are the primary source of power for the SPSs and therefore, should be maintained in the best possible conditions to guard against failure of power supply during flood periods. The transformers, circuit breakers, and other component parts of the switchgear, should be maintained and serviced as prescribed by the manufacturer. Switchgear should be kept in operating condition, including cleaning, by competent maintenance personnel. Equipment should be adjusted or serviced only by skilled mechanics. All electrical equipment, particularly the switchgear, should be kept as dry as possible. It is recommended that arrangements be made with the power company for the inspection of the electrical equipment, power lines, and transformers, and that the date pertaining to the inspection of these items should be added to the inspection report.

Pumps and Motors

Pumps and motors should be maintained and serviced in accordance with the instructions furnished by the manufacturer. These instruction manuals and other pertinent information were furnished at the time of the pump installations, and copies should be kept in the Superintendent's office as well as at each respective SPS. The pumps and motors should be trial operated and parts inspected as outlined under the operating instructions in the section of the manufacturer's manual.

Motors and pumps of different sizes have their own characteristic operating sound when in operation under various conditions. An operator will eventually become accustomed to this sound and should immediately investigate any noticeable change from this normal sound. Cleanliness can increase the efficiency and life of equipment. Moisture, dirt, dust, cobwebs, bugs, or oil causes deterioration and corrosion of mechanical and electrical equipment. Unnecessary oil on surfaces always collects dirt. Cleaning and painting is an important element in preventive maintenance to keep equipment in operation.

Adjustment or replacement of defective parts is a requirement of every preventive maintenance schedule. All the pumps in the SPSs are submersible units with sealed motor and pump assemblies. Disassembling equipment at regularly scheduled intervals by a factory representative, or a mechanic experienced with the equipment being checked, may be necessary for complete inspection.

Testing for proper operation is important. Testing procedures provided by the pump manufacturer(s) may show that equipment is out of adjustment and not capable of full efficient performance. Problems may then be discovered and corrected before a breakdown results.

All the pumps in the SPSs are submersible units with sealed lubrications systems. The manufacturer's recommendations regarding detection of seal leaks, oil spills, and other lubrication problems, should be carefully followed. All lubrication problems should be promptly addressed to reduce the time that an individual pump is out of service.

Heat

Conditions which cause excessive heat in operating equipment must be eliminated. The pump/motor control panels have high temperature warning lights for the bearings and motor windings.

Wet Well Depth Sensing Equipment

Pressure transducers and/or float switches are mounted in the SPS wet wells to sense the depth of water in the wells. The sensors trigger automatic operation of the pumps at the stations as follows in Tables 3A through 3F (note: local river stage refers to the stage at the USGS gage "Grand River at Grand Rapids, Michigan").

Table 3A - Market Avenue SPS

Repairs

Replacements or repairs of the equipment described herein, as determined by the inspections and tests, should be made by trained personnel in a timely manner. In taking remedial measures during periods of imminent flood, repairmen should bear in mind that use of the station may be required at any time, and therefore, repairs or replacements should be accomplished with the utmost speed without sacrificing quality of workmanship. In addition, contingency plans should be in place in case an SPS needs to be placed into operation before the repairs can be completed.

Trial Tests

Each item of pumping equipment should be trial operated as required herein. Manufacturer's instructions should be followed in testing pumps and equipment. Pumps should only be "bumped" for short periods (less than 15 seconds), rather than running dry. It is suggested that, in these trials, the motors be run consecutively and not concurrently. Procedures for operation during testing will be essentially similar to those described herein for regular station operation. During these trial runs, the inspector should be aware of indications that will give warning of impending failure of equipment.

Inspection and Trial Operation

SPSs should be inspected at least annually and more frequently during off-flood seasons. In addition, all equipment, including switchgear, transformers, motors, pumps, valves, and gates should be trial operated and checked annually. A schedule should be developed by the Superintendent to assure that these inspections take place on the prescribed intervals required. Manufacturer's recommendations for the equipment that should be inspected and the required frequency of inspections, as described in the equipment OM&I Manuals, should be followed. Sample check list and log forms for use in making inspections and trial operations of SPSs and equipment can be found in Appendix 2. The check list forms contain an inventory of tools and spare parts necessary for the operation and maintenance of the stations. Missing parts and tools should be replaced as quickly as possible. Any irregularities or damage should be noted and addressed in a timely manner. A report of any damage noted should be made promptly to the Superintendent.

Records Keeping - Records

Preventive maintenance programs are effective only if careful, accurate, and complete records are kept of all work done. The Superintendent cannot ensure that all personnel are carrying out their individual responsibilities and that all equipment is being properly inspected and maintained, unless careful documentation is maintained.

Inspection Records

The check list forms contained in Appendix 2 of this manual have been prepared with due reference to past experiences on similar projects. In order to maintain an effective preventive maintenance program, a record system should be maintained by the City covering inspection and service for each piece of equipment, as described. These scheduled inspections and inspection records should be maintained in a computer database and contain the following information as a minimum: 1) equipment and description; 2) the various parts of the equipment to be inspected; 3) work to be done (lubrication, adjustment, operation, cleaning, etc.); 4) normal frequency of inspection; and 5) date or dates when the inspections should be made. In addition, it should record: 1) date of actual service; 2) part of the equipment on which the maintenance has been performed; 3) person who performed the work; and 4) type of repairs required.

Operation

At least one SPS operator familiar with the City SPSs should be on duty at the SPS control center WRRF, whenever it appears that pumping operations will be required and remain on duty during the entire period of operation. They should be familiar with the equipment manufacturer's instructions and drawings and with the "Operating Instructions" for each station. The equipment should be monitored for operations in accordance with the "Operating Instructions" and care should be exercised that no overheating, undue vibration, or noise is occurring. Immediately upon final recession of flood waters, the pumping station should be thoroughly cleaned, wet wells flushed, and equipment thoroughly inspected, oiled, and greased. A record or log of SPS operation should be kept for each station, a copy of which should be furnished to the Superintendent following each flood.

Power Failure

Power failures during an emergency can be a cause of considerable damage to areas dependent on SPSs for protection. With this in mind, the City has several portable emergency power generators that can be hauled to the Market Avenue, Indian Mill Creek, Caledonia Street, and Palmer Street SPSs to provide auxiliary power. In order to prevent or minimize damage, the Superintendent should prepare a list of actions in their order of importance, to be followed in case of sudden power interruption that includes the transfer of power source to the generators. This list should be posted prominently in each station

Operation Diagrams

An SPS operation diagram for each SPS should be mounted in a frame and placed in the applicable SPS where it will be readily available. The operation diagram comprises a diagrammatic layout of equipment, description of control equipment, operating instructions, and a list of spare parts and tools required for ordinary maintenance. (Note: tools and spare parts should not be removed for use elsewhere.) The flood stage at which each SPS should be placed in operation is shown on the pump station operation diagram and on the location map.

Operation Log

The SPS operator at the operations center WRRF should keep a complete log of operations for the entire period over which SPS operations are carried out, i.e., from the time of notification that a stormwater pump has turned on until the last stormwater pump ceases operation. The log of operation should include river gage and water level readings at one-hour intervals, a record of all operational and maintenance duties performed, and the exact time of automatic (or manual) starting and stopping for each pump. At times when more than one pump is operating, the river gage and water level readings should be recorded at 15-minute intervals.

Grand River – Rate of Rise – SPS Operation

Sufficient time should be allotted to prepare the SPSs for operation when pumping may be required. It is the responsibility of the Superintendent to keep advised on predicted river stages and of possible additional rainfall, either locally or in areas tributary to the Grand River upstream of the City. This information will enable the Superintendent to make the necessary preparations for the operation of those features of the system for the protection of the area against high river stages in advance of their occurrence. River stage predictions for the Grand River and forecasts of local rainfall are issued by the NWS at Grand Rapids, Michigan, for specific periods. It is suggested that the Superintendent monitor available data from the NOAA Advanced Weather Service Advanced Hydrologic Prediction Service in order to monitor current river levels as well as predicted river levels:

(http://water.weather.gov/ahps2/hydrograph.php?wfo=grr&gage=gdrm4)

With this information, it will be possible to perform such operations as may be required to keep the SPSs ready for a flood event. The predicted stages are usually available from three to five days in advance. This is sufficient time to allow the Superintendent to make the necessary emergency preparations. Emergency action shall be in coordination with the City's NIMS and Emergency Management Operations organization structure for a flood emergency. The time period required to prepare the SPSs must also allow for the current state of readiness of each of the stations as well as the availability of experienced personnel. It is advisable to prepare the SPSs at least 24 hours in advance of any anticipated operation in order that sufficient time will be available for any required minor repairs. The SPSs should be inspected, trial operated, and made ready for operation at the river stage shown in Table 4.

Table 4 - Order of SPS Preparation

SPS	Local River Stage
Market Avenue	9.78
Wealthy Street	7.08
Front Avenue & Scribner Avenue	11.89
Indian Mill Creek	14.71
Caledonia Street	15.97
Palmer Street	11.55

The flood stage at which the SPS sluice gates should be operated for the diversion of the stormwater for pump ejection is shown on the operation diagram for each station. This operation is based upon stormwater runoff behind the protection works coincidental with high water. If there is no appreciable amount of stormwater runoff during a rapidly rising river, then the sluice gates may be placed in position for SPS operation when the rising river reaches the sluice gate seat elevation in the discharge well. The Superintendent should not conclude that pump operation will not be required. Pumping may be required at any time when the river stage exceeds minimum sump elevation and storm runoff is imminent.

Electric Service

Electricity for the SPSs is furnished by Consumers Energy. The point of contact for this utility is as follows:

Consumers Energy (a subsidiary of CMS Energy)

Principal Office

CMS Energy

One Energy Plaza

Jackson, MI 49201

Non-Emergency Calls: 1-800-477-5050
Emergency Calls: 1-800-477-5050
Email: businesscenter@consumersenergy.com

Pump Operation Precautions

The pumps should not be operated unnecessarily, when the water surface in the sump is below the minimum sump elevation shown on the operation diagrams and above the bottom of the suction bowl. Exceptions may be made during periods when the pumping equipment is being tested in expectation of high water and then only for short-periods of time. The continued operation of the pumps when the impellers are submerged but with the water surface below minimum design sump elevation, may result in excessive vibration and also cavitation of the pump impellers and bowls. Minimum design sump elevation for the SPSs are as follows:

Table 5 - SPS Minimum Sump Elevations

SPS	Minimum Sump Elevation
Market Avenue	587.67
Wealthy Street	589.45
Front Avenue & Scribner Avenue	600.90
Indian Mill Creek	609.67
Caledonia Street	609.67
Palmer Street	608.17

Unless the water surface is above minimum sump elevation, pump tests during routine inspections should be made when the water surface is below the bottom of the suction bell.

Lubrication

Submersible pumps are installed in all the SPSs. These pumps have sealed bearing and motor lubrication systems and do not require external lubrication. Leakage of water into the sealed lubrication system of any pump will set off warning indicators for the pump at the control center WRRF.

Manual Control

Before starting any pump during testing and/or maintenance, be sure that no one is in the discharge well or outfall structure. The pumps are operated from the panels or master control centers at each SPS.

Automatic Control

All the SPSs operate utilizing automatic control of the pumps. Automatic operation is controlled through pressure transducers and/or float switches that sense the depth of water in the wet wells. Each of the pumps in each SPS can be operated manually from the control panel or master control center located at the SPS.

In the event of failure of the automatic controls, the pumps should be controlled manually, and the pump manufacturer should be promptly contacted for repair. Allow a minimum of a 10 second interval between the starting of pump motors within an SPS.

Protective Devices

The motors for all the pumps in all of the SPSs are protected by under voltage relays which close automatically when the voltage returns to normal. Overload and short circuit protection is also provided. The protection is obtained by thermal overload relays and instantaneous overcurrent relays. The following relays are built into the breaker and reset automatically.

- Under-voltage relay
- Overload relay (Thermal overload - motor winding temperature and motor bearing temperature)
- Short-circuit relay (Overcurrent)
- Moisture sensor relay

If the station is on manual control when a breaker trips, the motor can be started again by pushing the reset button on the control panel or master control center.

Electrical Difficulties

It is suggested that in cases of a short circuit or other electrical difficulties arising during emergencies, the aid of Consumers Energy can be enlisted in an effort to locate and correct the cause (see contact information above).

Closing-down SPSs - Inspections

Immediately upon final recession of flood waters, switches, valves, and sluice gates should be restored to their normal settings. The SPSs should then be thoroughly cleaned, pump house sumps flushed, and equipment thoroughly inspected, oiled, and greased. After any flood stage in excess of 12 feet, as measured at the USGS Station 04119000, Grand River at Grand Rapids, Michigan, and at periodic inspections, all parts of the pumps should be checked thoroughly. The pump bowls should be inspected for cracks, pitting, or other damage. The impellers should be checked for damage, pitting, looseness on the shaft, etc. A log of SPS operation, a sample of which is included as Appendix 3, should be furnished to the Superintendent following each flood. It is advisable that a log of operations be filled in for all trial operations of SPSs, to be certain that all inspections and operations are carried out and that a complete record of operations is available for future reference.

Preventive Maintenance

Spare Parts - Availability

In order to be assured of operation of the station equipment when required, it is necessary to carry a stock of certain spare parts, or know where such parts may be obtained quickly as well as the time required to procure them. The Superintendent should obtain a parts list with their order number from the manufacturer so that any part may be obtained in an emergency without harmful delay.

Parts that are kept on-hand should be documented in an inventory system that is maintained in a manner that will allow the Superintendent to assure that sufficient supplies are available. The inventory will serve to remind the Superintendent when ordering additional parts is necessary. The spare parts list on the SPS inspection forms in Appendix 2 should be revised, as necessary, to accurately represent the parts that are on-hand at each SPS.

Care of Structures General

SPSs and applicable structures, such as gate wells, walls, etc., require periodic inspection. SPS sumps that contain seepage should be emptied for such inspections. Masonry structures should be checked for spalling, porosity, cracks, and breaks in expansion joint seals. Wood structural appurtenances should be checked for rot or warping.

Masonry Structures

No large masonry repair job should be undertaken without prior approval of the Superintendent or the City Engineer.

Spalling

When concrete spalling is allowed to continue, progressively greater damage is caused to the structure by the allowance of additional water and increased freeze/thaw action. It should, therefore, be repaired as follows:

- Repair concrete surfaces with appropriate repair and patch materials which permit carrying the patch to a feather edge where necessary. Follow the manufacturer's recommendations for the repair work closely, paying particular attention to surface preparation recommendations.
- Keep concrete from spalling by sealing the surface with appropriate sealer, suitable for contact with water.

Cracks

Cracks in concrete surfaces also lead to serious damage, especially when structures are exposed to heavy freezing. Therefore, it is important that all cracks be repaired immediately when found. Cracks may readily be repaired with appropriate non-shrink repair grouts. The source of the cracks should also be investigated to determine if building settlement, vibration, earthquakes, or unanticipated equipment loads are the root cause, which may require additional structural remediation measures.

Coating of Metals

Periodic painting is required of the parts of SPSs, equipment/materials storage buildings, closure materials, and other structures that require this type of protection in order to protect metal parts from corrosive action of water and other elements. Frequency of painting varies depending on type of coating used, method of application, and conditions of wear. Coat metal surfaces before corrosion becomes so severe that equipment is damaged. Prepare metal surfaces by abrasive blasting or by the method recommended by the coatings manufacturer. Follow the recommendations that pertain to atmospheric conditions during the coatings work, such as humidity and both ambient air and surface temperatures.

Only specially prepared coatings should be used on damp surfaces that will be encountered in the protection works. Corrosion-preventive compounds may be used in moist or wet places and in gate wells where normal coatings would not last. Again, refer to manufacturer's recommendations to determine the proper use of the coatings product.

Care of Valves and Gates

Valves and gates contain moving parts that must be exercised periodically and lubricated to ensure proper operation and to prevent potential corrosion. Excess corrosion could prevent operation of the gate.

Automatic Flap Gates

Automatic flap gates are installed on SPS discharge and SPS bypass stormwater discharge lines that are subject to submergence from river flood waters. The smaller size gates, 12-inches or under, are generally of cast iron and the larger gates are of cast steel. These gates require very little attention other than cleaning and lubrication.

At regular intervals, the hinged parts should be lubricated with grease. Some hinges are provided with fittings, or with openings, whereby they may be lubricated by use of a grease gun. In other cases, it may be necessary to unbolt the pins and remove the links in order to apply grease to the bushings. Disassemble only one side at a time and provide a stable support for the flap while the pins are removed.

- Annually, and more often if necessary, clean all the parts with a wire brush, to remove all dirt and scale.

- Wire-brush the bearing surfaces of the flap and seat and check for continuous contact. If flaps and seat rings do not line up properly, check bushings or hinge pins for excess wear and replace if necessary.
- Paint all steel parts with the proper type of corrosion-resistant paint.

Sluice Gates

Sluice gates are installed at SPSs and on storm sewer lines where manual control of flow is desirable. Their principle of closure is somewhat similar to that of the gate valve. Flood conditions may not require the operation of the sluice gates as frequently as may be necessary to keep them in good working order. These gates should be operated at regular intervals through their complete range of travel or, if flow conditions make this impractical, as close to complete closure as is possible. The stem screws are generally of bronze but steel stems have been installed in some instances. Precautions must be taken that the latter type is kept coated with grease to prevent corrosion. Corrosion may affect the threads so that closure of the gate can be accomplished only with great difficulty. During a flood emergency, considerable damage may result if the gate closure cannot be completed in time.

- Annually clean all the parts with a wire brush removing all dirt and scale. Clean the wedges and the slides thoroughly. Paint all the steel parts with a suitable corrosion-resistant paint.
- Remove all hardened grease and replace it with proper grade and type grease. Examine the grease box in two-speed floor stands especially for hardened grease and repack when necessary. Grease the slides and wedges of the gates thoroughly to facilitate ease of operation. Use non-hardening grease.
- Check and adjust the wedges so that, when the gate is in a closed position, each wedge will apply uniform pressure against the gate and cause the gate to bear against all points on the gate seat. Proper wedge adjustment must be particularly provided for sluice gates installed for unseating pressures.

Lubrication

Lubrication is an important part of preventive maintenance. The types of equipment and the conditions under which they operate make proper and regular lubrication practices extremely important. Proper lubrication prevents metal-to-metal contact, eliminates wear, and reduces corrosion. Improper lubrication causes damage to wearing surfaces, increases maintenance costs and power consumption, and results in power failure. Always keep machinery, including valves, wiped clean of oil. Investigate and correct oil leaks. Oil should be changed whenever there is any sign of contamination, stickiness or gumming. Most of the pumping equipment in the SPSs does not require lubrication other than that performed as a part of a regular inspection by the equipment manufacturer(s).

Lubrication instructions given herein include recommended types and intervals for certain equipment. However, these are to be considered only as guides and may require modification. The manufacturer's instructions, or the manufacturer, should be consulted and the advice of oil companies sought to determine the types of lubricants to be used on all equipment. Lubricated mechanisms generate heat which reduces the viscosity of the lubricant. Knowledge of temperatures to be encountered is necessary to enable the oil companies to correctly determine whether the proper grades of lubricants are being used. The maximum temperatures at the points of lubrication should be determined with the aid of a thermometer when the equipment has been operated under load for any length of time.

Condensation

It may seem proper that as long as the correct amount of oil or grease is in a bearing, and no noise or heat is noticeable, that the machine would operate indefinitely. This, however, is not true as the SPSs are usually damp and condensation is present. Should the lubricating film break down, the presence of moisture could lead to corrosion of the metal surface.

Lubricant Deterioration

The principal deteriorating elements in lubricants are dirt, water, oxidation, and excessive heat. If these are controlled, lubricant deterioration between lubrication periods is less likely. Guard against dust, grit, and abrasives getting into containers used for storing lubricants. Wipe spouts and lips clean before using container; wipe fittings clean before filling with lubricant.

Pumping Equipment

The pumps installed in the six SPSs are all vertical submersible type. Their reliability during flood events is of major importance. Pumping equipment operates with little trouble if it receives proper preventive care. The City contracts out most of the annual pump maintenance. The matter of keeping necessary records and following the rules pointed out above, with reference to motors, are just as applicable to pumps. Manuals for each SPS that include troubleshooting procedures, can be found in each of the SPSs. The operator should familiarize themselves with these manuals prior to a flood event that requires SPS operation.

Pump and Motor Alignment

The submersible pumps used at all SPSs have the pump and motor within the sealed pump casing. Check the alignment of the pump and motor when bearing or motor warning lights are lit on the pump control panel or when excessive vibration occurs. If misalignment should recur frequently, the pump manufacturer's representative should be contacted for service and the pump taken off line until service is performed.

Bowls, Water Passage, and Impellers

Look for pitting, wear and corrosion on bowls, water passages, and impellers. Corrosive water affects performance and dependability of the pump. If pitting occurs only in the lower sections of the pump (bowl and impeller), cavitation may be taking place. Cavitation may result from operating the pump when the level of the water in the sump is too low. Cavitation causes severe pitting and a characteristic spongy appearance in the metal. It generally affects the entrance portion of the impeller, though it may also occur in the casing. Pumps may be operated for dry test runs when the sump water is below the intake of the suction ball.

Power Consumption

An indication of either electrical or mechanical difficulties may be determined by comparing ammeter and voltmeter readings for each motor during no load test runs with past records for similar conditions. A noticeable increase in the ammeter reading with a normal voltage indicates an undesirable condition, which should be traced. Under full load, the current demand should not exceed that shown on the data plate of the motor. A check may be made on the pump and motor unit operating efficiency, when no ammeter is in the line to the motor. Watt-hour meters are installed at all stations for recording the electrical energy consumed in operating the station. When electrical energy is being used in the station, the horizontal disc in the meter rotates. The speed with which it rotates is dependent on the amount of current being consumed. Some specific number of revolutions for two minutes should be counted and the nearest even figure (such as 50, 60, or 75, etc.) be adopted. All switches drawing electrical energy through the meter, except the pump unit being tested, should be in the open position when making such a test. The figure adopted should then be timed to the nearest second. All future readings can then be compared with past records by checking the time for this same number of revolutions under no load (or identical) conditions. Any appreciable variation in the time will indicate some difficulty in the motor or pump and should be investigated.

Disassembling and Inspecting Pump

The pump and motor for all of the submersible pumps are sealed units. The frequency of completely disassembling the pump for a thorough inspection will be dependent on local conditions and manufacturer's recommendations. It is cautioned that such inspections should not be deferred for long periods, as costly breakdowns may result at a most critical time. These inspections should only be made by a manufacturer authorized service technician.

Pump Lubrication

The lubrication system for the pumps in all SPSs is sealed within the submersible pump casing. The lubricant should be replaced during normal servicing by the manufacturer authorized service technician.

Pump Bearings

All of the SPSs have submersible pumps with sealed motors and bearings. The lubricants in these sealed units must be changed on occasion as instructed in the manufacturer's OM&I Manual. Bearing temperatures should be checked if there is any indication that they are overheating or are not running smoothly. After a pump has been in operation long enough for the bearings to be at normal temperatures, the control panel should be regularly checked to see if any bearing or motor winding temperature warning light is on. Should the bearing or motor winding temperature warning light on the control panel turn on for any pump, the operating conditions should be investigated in consultation with the pump manufacturer. An overheated pump should be shut down and an alternate pump turned on.

The lubrication of bearings is of the utmost importance in the efficient operation of any pump or motor, regardless of the size. The lubrication of bearings should follow the manufacturer's recommendations regarding inspection, pump removal and disassembly, cleaning of bearings and motor, proper type and grade of oil, lubrication of bearings, installation and inspection of seals, pump reassembly and installation. It may be necessary to retain the services of the manufacturer or a qualified pump servicing company to perform lubrication of the submersible pumps.

Electrical System

Where electrical equipment is to be handled or where contact is possible during inspection, the equipment must be de-energized and effectively grounded. A grounding harness should be applied where applicable.

Switchgear Equipment

A test check and inspection should be made of switchgear equipment at all regular inspections. A thorough general check and inspection should be made at least once every year. Switchgear equipment includes all component parts of the switchboard itself and all auxiliary equipment. This equipment consists of switchboard panels, instruments and meters, control and transfer switches, indicating lamps, test blocks, wiring and insulation, bus bars, draw-out devices, switches, relays, circuit breakers, and lighting transformers. Circuit breakers and transformers are discussed elsewhere in this section.

- The switchboard and component parts should be cleaned regularly. This should be done preferably with a vacuum cleaner having an insulated nozzle. Check the general condition of all parts. See that all covers are in place and in good condition, that there are no broken parts and no loose or missing screws and nuts. Metal-enclosed switchgear should be opened at intervals and all internal parts inspected for surface cleanliness. Any accumulated dust should be removed and all insulators carefully cleaned. These precautions are especially necessary if the equipment is located where metallic dust, cement dust, fine powder dust, salt spray, or acid fumes are present.

- Instruments and motors should be examined to see that all are in good condition, are registering properly, and have no broken or cracked glass, or damaged cases. Voltmeters, ammeters, and watt-hour meters should be tested and calibrated if necessary.
- The operation and control and instrument transfer switches should be checked, and the contacts of all switches inspected. Damaged parts should be repaired or replaced. The inspection should also include the operation of the controlled device.
- All indicating lamps should be examined and weak or burned out lamps replaced. The operation test of controlled devices should include checking of the proper indication by the lamps of the "open position" (green light) and "closed position" (red light).
- Test blocks should be examined to see that the contacts are in good condition and that there are no loose connections.
- Bus bars and connections should be examined. If they appear to be overheating, the cause of overheating should be found and corrected. If due to poor or loose connections (loose bolts and nuts in the bolted joints), these should be tightened. Where joints are badly overheated, it may be advisable to dismount them, clean the surfaces and reassemble them, making sure that all nuts are properly tightened. Should oxidation reoccur at an electrical joint after having been cleaned of oxide formation, it is advisable to cover such parts with a protective coating of a non-corrective lubricant (Vaseline, sloughing compound, or the like). "Cup" grease or other grease which hardens on exposure to air, should not be used.

Motors

The pump motors are all sealed within the casings of the submersible pumps. The pump motors should be maintained as recommended by the pump manufacturer's OM&I Manual. Only manufacturer authorized service technicians should perform maintenance on the pump motors.

If warning lights are lit for any of the following conditions on the individual pump control panel, the pump should be shut down and a manufacturer authorized service technician called to determine the cause of the problem and the maintenance required.

Market Avenue SPS Warning Lights

- High Motor Winding Temperature (each pump and sump pump)
- Pump Seal Leak (each pump and sump pump)
- Wet Well Level High

Wealthy Street SPS Warning Lights

- Trouble (each pump, sump pump, and flow channel pump)
- Low Wet Well Level
- High Water Alarm

Front Avenue & Scribner Avenue SPS Warning Lights

- Trouble (each pump and sump pump)
- Low Wet Well Level
- High Water Alarm
- High River Level

Indian Mill Creek, Caledonia Street, and Palmer Street SPSs Warning Lights

- Temp/Seal Failure (each pump and sump pump)
- Wet Well Level Alarm

The pump should not be returned to service until the cause of the problem is diagnosed and corrected. A regular system of inspection will tend to make motor operation more reliable. In order to facilitate locating the cause of forced shut-downs of pump motors, it is advisable to keep records of all troubles and cures of chronic cases. The most dependable motor service with a longer period of motor life can be provided by adhering to the following rules: (1) keep a regular inspection schedule; (2) know the condition of the apparatus at all times; (3) correct any indication of weakness before the motor fails; (4) motor repairs should be made only by a competent technician.

Lighting System

Maintenance of the SPS interior and exterior lighting systems in good condition is an important factor in preventing accidents. Lighting reflectors should be kept clean and lamps replaced when burned out. All wiring should be maintained free of conditions conductive to damage or faulty operation of the system.

SPS Power Transformers

As compared with most electric apparatus, transformers require relatively little attention. The extent of the inspection and maintenance required is governed by the importance of instantaneously available and continuous service, operating conditions, such as ambient temperature, unusually dirty atmosphere, and heavy fogs. In flood protection project installations, availability of immediate and continuous service is of utmost importance and a greater degree of attention is justified than would ordinarily be given where life and property were not endangered by a power failure. It is suggested that Consumers Energy be engaged to make all inspections on the SPS power transformers, other than visual, and to perform all maintenance work on them as well as on the fused disconnect switches. Transformers mounted in the open and exposed to the atmosphere are provided with weatherproof casings.

Control Panel and Lighting Transformers - Dry-Type

Dry-type transformers are generally used for the control panel and lighting circuits and are located inside the SPSs. If dust is found on a transformer, blow off with clean, dry, compressed air. A dust coating acts as an insulator and prevents the transformer from cooling properly. Do not block air circulation around any transformer.

Fused Disconnect Switches

Fused disconnect switches are installed on the incoming power transmission lines at the transformers and are used to protect the transformers from excessive overload. They are of the knife-switch variety and carry cartridge-type fuses. The disconnect switches are used to open the live lines when the SPS is out of operation; otherwise current will be consumed by the transformers. The disconnect switches should only be operated when the switches in the SPS are in the open position. These switches require very little maintenance. They should be inspected during the time that Consumers Energy inspects the transformers. Inspection consists of examining the contacts, insulators, mountings, and operating mechanism.

The contact surfaces should be cleaned when necessary. This may be done by opening and closing the switch several times in succession. If required, and with full care being taken to keep the amount of metal removed to a minimum, the contact surfaces may be rubbed very lightly with very fine sandpaper. Removing too much metal results in poor contact and overheating. The condition of contact can be checked by attempting to insert a 0.002-inch feeler gage between the blade and the contact at all accessible joints. If the gage can be inserted, adjustment should be made. In replacing fuses, use the size and type that will furnish adequate protection for the transformer. Be sure that the surfaces of insulators are clean.

Circuit Breakers, Knife Switches, Fuses, Insulators, and Relays

Circuit breakers, knife switches, fuses, insulators, and relays perform the purpose of protecting the SPS electrical equipment and pump motors. Circuit breakers are intended to open a circuit, thus stopping the flow of current, should the current exceed a predetermined rate through these safety devices. Knife switches manually open a circuit to de-energize equipment for repair, testing, or maintenance.

Circuit breakers, knife switches, fuses, insulators, and relays must be given proper care and maintenance. Quite often trouble is forestalled by tightening a wire or switch, replacing spring cotter pins, readjusting and cleaning contacts, keeping latches free of corrosion, etc., when regular periodic inspections are made. The frequency of complete inspection depends a great deal on ambient conditions, but, in general, a complete inspection should be made at least once a year, preferably just before the flood season. An inspection should always be made immediately when it is determined that the circuit breaker has been opened by a severe short circuit. Inspections should only be made by a qualified electrician.

Lightning Arresters

Low-resistance arresters to grounds have been installed on equipment where necessary to secure effective protection from lighting or voltage surges. Annual inspections should include the following:

- Check for loose line and ground connections. Be sure all electrical connections are clean and tight and make good electrical contact.
- Examine housing for chipping, shattering, cracks, or other damage, and for loose bolts on assembly or mounting hardware.
- Make sure ground connections are continuous and securely fastened to grounding rods.
- To prevent external flashovers, maintain some clearance between line terminal and grounded structures, hardware, line conductors, vegetation, etc., as between line conductors on the original installation. Keep external surfaces of arresters clean to prevent flashovers, especially where circuits carry 5,000 volts or more.

Bushings and Insulators

Bushings at transformer installations ordinarily require little, if any, attention. Maintenance is ordinarily limited to cleaning. The frequency of this operation depends on the prevalence of cement or metallic dust, salt spray, or acid fumes in the atmosphere.

- The same measures should be taken for the porcelain sections of the bushings and insulators as for the lightning arresters. Dirt deposits under moist conditions tend to form a conductive coating and should be cleaned off to prevent flashover. Check visually for cracked or broken porcelain. The porcelain transformer bushings should be tested with special testing equipment similar to that used by Consumers Energy.
- Clean bushings and insulators as required by local conditions. This operation should be performed by Consumers Energy on hot lines.

Grounds

Ground resistance to all equipment should be tested occasionally. See that transformer tank, outdoor switchgear housing, operating levers, lightning arresters, and metal fencing (around ground level substation) are properly connected to grounds. Ground resistance should not exceed 15 ohms for driven grounds. Test for accidental grounds on ungrounded equipment. Grounds can best be tested with equipment similar to that used by Consumers Energy.

Cable and Wire

Periodic inspection of cable and wire is the best method of preventing failure. Such inspections should be made for poor thermal conditions and potential danger spots. Exterior wiring should be noted for tension between anchor points which might be off-standard. Wires which are too slack or too tight should be adjusted to proper tension. If cables appear to be carrying excessive temperature, determine the cable temperature by attaching a suitable thermometer to the cable surface. Check with Consumers Energy for proper temperature for cable size and amperage load. Overheating can be caused by overloads or the presence of external sources of heat and will dry and harden the insulation. This in turn either increases the dielectric losses or produces cracks in the insulation and thus hastens ultimate failure. Oil on rubber insulated cables will cause swelling and softening of rubber.

Trees near overhead lines are a potential source of trouble because they may break and blow across wires during a storm. The limbs may break wires or cause a short circuit. To avoid these type of power interruptions, trees should be trimmed as necessary. For limbs less than 3-inches in diameter, allow at least 8-feet of overhang clearance, at least 4-feet of side clearance, and at least 3-feet of underneath clearance. Perform heavy pruning and heading the back of old trees in late fall or during winter when trees are dormant. Trim new growth soon after the spring growing period.

Poles and Appurtenances

Poles require very little maintenance which is generally limited to replacement when they show signs of rotting. Poles, cross arms, pins, bolts, braces, guys, anchors, and insulators should be inspected and repaired/replaced by Consumers Energy.

Depth Sending Pressure Transducers

The operation of pumps is automatically triggered by the water depth in the wet wells of each SPS. This level is monitored by pressure transducers that are connected to the Wet Well Level Transducer Panels inside each SPS. The pumps are placed in operation based on the readings on the Wet Well Level Transducer Panel. This equipment should be inspected and checked to insure the readings are accurate. The transducer should be cleaned periodically. Accumulation of grease, oil, or debris can result in inaccurate readings.

Mobile Pumps

General

All low areas, in all reaches, are served by storm water collection systems discharging directly to the Grand River. Where needed stormwater pump stations exist to keep interior flooding to a depth of less than 12-inches on average during extreme events. Isolated short duration ponding, averaging less than 12-inches in depth, may occur in some areas during extreme rainfall events. These areas (streets) are listed later in this report. If necessary, the City will close these streets to traffic until the water has receded or pump the water from the streets. Provided in Table 6 is a list of mobile pumps that the City has available to address shallow ponding.

Table 6 – Mobile Pumps Available to Localized Flooding

Equipment Description	Quantity on Hand	Max. Discharge per Pump* (cfs)
4" Gorman-Rupp Trash Pump	1	1.58
6" Gorman-Rupp Trash Pump	2	3.45
4" Godwin Trash Pump	1	1.96
6" Godwin Trash Pump	1	4.41
6" Godwin High Head Trash Pump	1	4.51
6" Flygt Submersible Sewage Pump	1	5.35

*Assumes static lift = 10 feet.

The pumps are all stored and maintained at the WRRF.

Maintenance and Inspection

Each mobile pump trailer should be inspected annually to confirm full tire inflation, operating tail and turn signal lights, an operational trailer hitch, and overall condition of the trailer frame. Any problems with the pump trailer should be corrected immediately.

The pump engine oil should be changed annually and the used-oil recycled. The pumps should be lubricated in accordance with manufacturer's recommendations. At least 2 times a year, each pump should be tested to confirm successful motor startup, pump self-priming, and smooth operation. For the pump tests, the pumps should draw water from and discharge it back to the Grand River. Any problems with pump operation should be resolved immediately in accordance with manufacturer's recommendations.

Operation

When the river stage at the USGS gage (station no. 0419000) reaches 21 feet and the flood stage hydrograph shown on the National Weather Service (NWS) *Advanced Hydrologic Prediction Service* internet web site (found at http://water.weather.gov/ahps2/hydrograph.php?wfo=grr&gage=gdrm4) predicts a continuing rise in the flood stage, the mobile pumps shall be moved from their storage location at the WRRF and staged throughout the City as shown in Table 7.

Table 7 Mobile Pump Staging Locations
Parking Lot, southwest corner of Monroe Avenue and Sixth Street intersection
Fulton & Market Parking Lot, southwest corner of Market Avenue and Fulton Street intersection
Southwest parking lot at DeltaPlex Arena on West River Drive NE at Turner Avenue intersection in Walker (coordinate with Walker City Manager)
Kent County Road Commission work yard on Scribner Avenue

When the water depth at each local flood location approaches 9 inches and rising, the mobile pump staged nearby should be moved to the flood location, local traffic should be diverted if necessary, and the pump set-up to begin pumping. The water would be pumped directly to the river or to an adjacent storm water drainage system capable of handling the increased discharge. Pumping should continue until it is clear to the pump operator that water levels in the flooded area are decreasing and will not rise when the pump is turned off. Once the pumping ceases, the mobile pump should be returned to the WRRF for cleaning and storage.

Miscellaneous Facilities

Maintenance

Miscellaneous structures and facilities constructed as a part of the protective works and other structures and facilities which function as a part of, or affect the efficient functioning of the protective works, should be periodically inspected by the Superintendent and appropriate maintenance measures taken. Areas used for ponding in connection with SPSs, or for temporary storage of interior runoff during flood periods, should not be allowed to become filled with silt, debris, or dumped material.

Under the classification of miscellaneous facilities are the ponding areas utilized for storage of large runoff quantities, submerged storage tanks that could float as a result of high groundwater levels, and structures that could be flooded including:

- WRRF underground storage tanks
- Market Avenue SPS discharge control sluice gates (2 gates)
- Garfield Avenue at Westside Ditch discharge control sluice gate (1 gate)
- WWRF primary effluent retention basin
- WRRF stormwater and sanitary sewer valves in manholes in earth dike
- West end of Elmdale Street at river
- Intersection of Crosby Street, NW, and Turner Avenue, NW
- Eastside interceptor sanitary sewer along east bank of river
- Stormwater junction chamber in grassed cloverleaf area, approximately 30-feet west of the west curb line of Market Avenue, south of U.S. Route 131 north bound exit ramp (east bank of river)
- Intersection of Crosby Street, NW, and Scribner Avenue, NW
- Elmdale Street sanitary lift station
- Southeast interceptor sanitary sewer outflow chamber sluice gate at Market Avenue Bridge (1 gate)
- Fulton Street /Monroe Street, NW/Market Avenue, SW, intersection
- Wealthy Street SPS
- Intersection of Jenette Avenue, NW, and Sylvia Street, NW
- Intersection of Tenth Street, NW, and Front Avenue, NW
- Myrtle Street, NW, extension at Scribner Avenue, NW
- City Market Avenue property
- Riverfront building low-level windows
- Forslund Building basement
- Convention Center underground parking garage
- Convention Center entrance doors

Ponding Areas

The ponding areas used for temporary storage of interior runoff will ordinarily require little attention during flood periods other than the taking of usual precautions to block roads that might be cut off in extreme cases. Storm drain inlets should be kept clear of debris so that water will drain when the Grand River water level recedes. Water should be pumped from the following intersections to the river using portable pumps, if necessary:

- Intersection of Tenth Street, NW, and Front Avenue, NW
- Myrtle Street, NW, extension at Scribner Avenue, NW
- Wealthy Street, SW, and Market Avenue, SW
- Market Avenue, SW, between U.S. Route 131 and Fulton Street

- Fulton Street between the parking lot on the southwest corner of the Fulton Street/Market Avenue intersection and Ottawa Avenue, SW
- Campeau Avenue, NW, between the walkway leading to the Blue Pedestrian Bridge and Pearl Street, NW
- Monroe Avenue, NW, between Frank Street, NW, and the railroad crossing south of Sweet Street, NW
- Monroe Avenue, NW, at the intersection of Palmer Street, NW

WRRF Submerged Storage Tanks and Primary Effluent Retention Pond

Underground storage tanks and the bottom of the primary effluent retention pond at the WRRF could float if they are not partially filled during a flood event that causes the groundwater levels to rise. The groundwater level around the tanks and primary effluent retention pond should be checked at regular intervals during a flood event. As needed, the tanks should be filled with water to prevent tank floating. The primary effluent retention pond should be filled to the same level as the Grand River (refer to the WRRF O&M Manual for guidance).

SPS Flooding

The Wealthy Street SPS and the Elmdale Street sanitary pump station are subject to overland flooding during large flood events. At the Wealthy Street SPS, sandbags should be placed around the perimeter of the control building to protect electrical equipment. At the Elmdale Lift Station, flood water levels could exceed the top of the wet well elevation. In this case, the lift station pumps should be turned off. Homes with floor drains that flow to the lift station will be flooded when the top of the wet well elevation is exceeded by the flood elevation.

Sanitary Sewers

The Eastside Interceptor sanitary sewer could float when the Grand River rises to flood stage. Operations of the Market Avenue Pump Station and Market Avenue Retention Basin should be adjusted as necessary to maintain a water level in the sewer no lower than 15-feet below the Grand River level.

Operation

Miscellaneous facilities should be operated to prevent or reduce flooding during periods of high water. Those facilities constructed (or utilized) as a part of the protective works should not be used for purposes other than flood protection without approval of the Superintendent.

Special O&M During High Water Periods

General

This section of the manual is supplementary in nature and describes standard practices that have been used to advantage on levees and floodwalls during high-water emergencies. Most of the methods described herein have been developed during years of experience with the various problems that arise during periods of high water, but they are not intended to restrict the Superintendent, or others concerned, to a rigid set of rules for every possible circumstance. In all cases, the Superintendent should follow standard engineering practices in meeting emergency situations.

Earth Embankment (Levee) and Floodwall System

The earth embankment and floodwall system may be subjected to certain dangers during flood periods from current, ice, debris, or wave action. These dangers diminish with the degree of maintenance that the earth embankment system receives during normal river stages. Properly constructed earth embankments (levees) and floodwalls, if adequately maintained, should withstand any major flood. However, certain unexpected conditions that arise during floods and threaten the earth embankment (levee) system may be met with assurance if prompt action is taken and proper methods of treatment are used. Measures to cope with sand boils, seepage, sloughs, wave wash, ice impact or jams, scour, and possible overtopping of neglected low spots in the earth embankments (levees) and floodwalls, are described herein. Prompt and adequate maintenance will result in minimizing the necessity for such measures during high water periods.

Preparedness

It will be noted in the following paragraphs that various materials and equipment are required to combat such unforeseen conditions as may arise during a flood emergency. It is imperative to know in advance just where such materials and equipment may be secured in emergencies, even though such emergencies may never arise. A definite plan should be prepared by the Superintendent that will enable him to foresee just what materials he will need, where they may be obtained in time for use, what manpower and transportation will be needed, what routes will be open at particular river stages, etc. This information will be particularly vital as the possibility of earth embankment (levee) and/or floodwall overtopping is approached. Such a plan, once formed, must be checked prior to each flood season since the sources of material supply could very likely change during the year. The essential element in a flood emergency is time, therefore local interests should give early attention to the preparation of a list of sources from which the necessary labor, lumber, hardware, sandbags, suitable earth for sacking, equipment, etc., can readily be secured to cover any contingency. Such items should be provided as rapidly as is possible when the need arises.

Materials

For all practical purposes, the materials of consequence used during flood emergencies are:

- Sandbags
- Lumber (rough, common pine)
- Sacked or loose earth
- Plastic tarps/sheets
- Wire (No. 9) and nails

A reserve supply of emergency materials should be kept on hand or be immediately available through arrangements with local suppliers or manufacturers. The principal consideration in obtaining lumber and other materials for emergency construction is their availability. Stored materials subject to damage or deterioration should be checked, and damaged portions replaced, before the start of each high water season.

Sacked Earth or Loose Earth

Sacks filled with earth can be used in almost every phase of emergency high water work. It may best be used when the point of placement is readily accessible by truck. It is advisable to use sacked earth under other conditions. Sacks should be filled about two-thirds full, with the material shaken down into the sack loosely (never tamped). Sacks need not be tied or sewn together at the top if used for capping or on the land side of the earth embankment (levee). Earth-filled sacks used for wave wash, or as weights, should be filled and the ends tied. Sand should be used only if earth is not available, or if the time element is an important factor as in the distance required for hauling. In some cases, it may be better to fill sacks elsewhere and haul them to the site.

Sandbags

The term "sandbags" as used in flood emergency construction might to be considered a misnomer in that the bags are ordinarily filled with earth. Sand is used only when they are used as weights or when earth availability is a problem. An adequate initial supply of sandbags should be maintained to make all necessary sandbag closures. Bags must be checked annually to detect any deterioration. They should be stored in a dry location where there is free passage of air around them to prevent spontaneous combustion. Any bags that are damp, wet, or oily, should not be returned to storage with the main supply. Sacks used for sandbags are mildew treated burlap or ultraviolet light-resistant polypropylene. When they are two-thirds full, they hold about one-third cubic foot of earth. Any type and suitable size sack can be used if burlap or polypropylene is not available.

Earth

The most suitable type of earth to be used for flood emergency construction is a silty loam or a silty clay loam; however, almost any available soil can be used with plastic tarps/sheets to provide a water proof barrier or liner.

Preliminary Preparations

The City should have a trained organization of Supervisors, who may readily be assembled by the Superintendent immediately upon receipt of information that a Grand River flood stage > 12' is forecast. Each Supervisor should have charge of a definite section of levee, floodwall, or structures that may be endangered, or the operation of which is essential during high water. This organization should be capable of quick expansion so that each Supervisor will have sufficient personnel to carry out his function. As his/her initial activity, each supervisor should go over his/her entire sector, and part of adjacent sectors, making a detailed inspection, particularly with reference to the following matters:

- Sector limits; ascertain that the dividing line between sectors is plainly determined and, if necessary, marked
- Condition of earth embankments (levees) and floodwalls and recent repairs
- Condition of drainage structures
- Transportation facilities; roads, rail, and traffic/rail control signals
- Material supply; quantity, location, and condition
- Communications; locate and inspect all available telephones in the sector that may be needed

Initial Work

After initial inspection, the Supervisor should perform the following work immediately where required. To accomplish such work he/she should have organized labor and obtained the supplies and equipment as may be necessary.

- Where new earth embankment (levee) construction has been performed on the riverside of earth embankment (levee), preparation should be made in advance to combat wave wash by facing with sandbags.
- Inspect all flap gates and sluice gates, before the seats are submerged, to ascertain that they are clear of obstructions and will seat properly.

- Ascertain that all roads to and along the earth embankments (levees) and floodwalls are in good condition. The Superintendent should obtain the assistance of the local road forces to have all necessary roads put in usable condition. The Superintendent should be informed at all times of all roads in the vicinity that are closed for repair. An up-to-date route layout should be available at all times showing routes over which any and all types and weights of equipment can be sent to any point in the protection system.
- Locate necessary tools and materials (sacks, sandbags, lumber, lights, etc.), and distribute and store them at points where active maintenance is anticipated.
- Check and obtain repair of all telephones necessary for operation; obtain lists of all team forces, bus, automobile, and truck transportation that can be made available.
- Make thorough arrangements with reliable citizens of the community for supply, transportation, subsistence, and shelter for the necessary labor.
- Investigate all drainage ditches on the landside of the earth embankments (levees) and floodwalls and open these drains when obstructions exist.
- Remove all explosives of any kind from the vicinity of the earth embankments (levees) and floodwalls.

Methods of Treatment – General

After the above preliminary organizations and precautions have been completed, the various methods of combating possible flood emergencies are ready to be employed. Temporary treatment of emergency situations is described in the following paragraphs.

Seepage - Earth Embankments (Levees)

Seepage emerging from the slope, or at the landside toe of an earth (levee) embankment, can cause sloughing of the slope or even lead to piping (internal erosion) of fine sand or silt material. In many cases, high water stages do not act against the earth embankment (levee) long enough for this to happen, but the possibility of the combination of high water and a period of heavy precipitation may bring this about. In order to prevent sloughing where the slope is deeply saturated, small V-shaped drains should be cut in the landside slope to remove the seepage water. If the earth embankment (levee) should become saturated over a relatively large area, it may become necessary to take the measures outlined below to prevent sloughing.

Slope Drainage - Earth Embankments (Levees)

Drainage of the slope should be provided at all places on the landside of the earth embankment (levee) where seepage appears. The drains should be V-shaped, no deeper than necessary, and never more than 6-inches deep. The sod should not be cut unnecessarily. In all instances, drains should be cut straight down the earth embankment (levee) slope. Where possible near the toe of the slope, the small drains should be Y'd together and lead into large drains which lead to ponding areas or SPSs.

Sloughing - Earth Embankments (Levees)

Sloughing is the slipping, or flowing out of position, or the landside slope of an earth embankment (levee), due to being saturated through seepage to the point where that part of the earth embankment (levee) becomes unstable. Reaches in the earth embankment (levee), where the material is of such nature that prolonged high stages may cause sloughing, should be thoroughly drained as described above. After this operation, a single layer of willow brush, if obtainable, or any small trees or limbs, should be laid up and down the slope, butts upward and tops downward, and weighted with earth-fill sacks. If the slope begins to slough down, a log or heavy timber should be laid on top of the willows at the toe of the material sloughed off and fastened to long stakes which have been driven several feet into the ground. A buttress of earth filled sacks should then be built at the toe and extended up the slope. The buttress at the toe should be built in the shape of a small berm. Sandbags or weights

should not be placed more than two-thirds of the distance from the toe of the material sloughed off to the bottom of the slough. See Figure 2.

Sand Boils - Earth Embankments (Levees) and Floodwalls

A sand boil is a definite stream of seepage water issuing from the earth, usually near the landside toe of an earth embankment (levee) or floodwall. The source of this water is usually from pervious materials underlying the earth embankment (levee) or floodwall. Sand boils are serious in any location and should be watched closely, especially when within 100-feet of the earth embankment (levee) toe or floodwall. A sand boil which discharges clear water in a small steady flow, is ordinarily not a serious threat to the safety of the earth embankment (levee) or floodwall, and need not be ringed. However, if the flow increases or carries a substantial load of sand and silt, corrective action should be taken immediately to prevent possible earth embankment (levee) or floodwall failure. A neglected sand boil may gradually undermine an earth embankment (levee) or floodwall and cause failure by subsidence of the levee.

The accepted method of treating a sand boil is to construct a water tight ring of sand bags around the boil, high enough to create a head of water within the ring sufficient to reduce the velocity of flow. See Figure 3. The ring should not be built to a height which stops the flow of water completely. The sacks are filled about two-thirds full of earth, and are laid flat in a ring around the boil with the joints staggered, each layer being placed in alternate directions. The sacks should be lapped at least one-third. The ends are left untied, and are lapped under the sacks. Each complete layer should be tramped or tamped into place after placement. The base width of the ring should be not less than one and one-half times, and preferably twice, the contemplated height. A drain is provided by omitting one bag in the top layer, or by constructing a V-shaped drain of two boards or a piece of sheet metal inserted near the top of the ring.

If ground weakness is indicated close to the sand boil, it is well to include the weak ground within the ring, thereby avoiding the possibility of a breakthrough later. Several sand boils within a relatively small radius should be enclosed as a group in a sub-levee or single sack ring. Sand boils at the toe of the levee or floodwall are sacked in the same manner as those away from the earth embankment (levee) or floodwall, and in the case of an earth embankment (levee), using the earth embankment (levee) slope as one side of the closure.

Sandbags, Cotton Bagging, or Plastic Sheeting

Sections of cotton bagging or plastic sheeting should be placed over the washed areas as shown on Figure 4. If the washed area is considerable, or protection is desired to a predicted higher stage, the bagging may be cut into lengths and laid up and down the slope to cover the area. The strips should be lapped with the current to prevent lifting. See Figure 5. Bagging must be thoroughly weighted down with stone or sandbags to be effective. In using this method, stakes should be driven through the bagging approximately 6-feet apart below the water surface and at the top of protection, to be sure that the bagging is being held in place. As an alternative, sacked earth material may be used as a means to fill small washed areas or holes. The sacks should be placed close together beginning about 2-feet under the water surface. Each succeeding row of sacks should overlap the preceding row like shingles on a roof. The joints should be staggered. All holes should be filled with sufficient sacked earth to meet the original grade line. All sacks should be tamped into place so that wave action will not readily wash them away.

Log Boom

If sacking for the prevention of washes caused by floating ice cannot be placed or used effectively, it is desirable to make a log boom of any available large timbers to deflect ice from the embankment. The logs should be fastened together with steel staples and coil chain, or heavy wire, with a distance of about 12-inches between end faces. The staples at each end of the log should be driven on a line parallel to the axis of the log, and should be allowed to protrude sufficiently to permit enough room for rotation of the logs. Wire or chain should be

passed or wrapped around the logs as staples may pull out. The boom should be strung along the levee slope and anchored about 15-feet out from the water's edge by means of logs or timbers, spaced not more than 50-feet apart, tied to stakes near the shore line. See Figure 6. The booms should also be anchored to the slope approximately every 200-feet, or as conditions may require, with cables placed at angles of about 45 degrees. Additional stakes can be driven up the levee slope in anticipation of a rising river, and the anchor logs and cable ties adjusted as required. This method of protection is particularly effective against ice flows.

Scour

Current scour, or erosion of the riverside slope of the levee or along the floodwall footing, is caused by abnormally high current velocities. Conditions which cause scouring may be detected by the appearance of eddies and general turbulence of the water. Immediate steps should be taken to protect the levee when current scour appears.

Overtopping - Earth Embankment (Levee)

Overtopping, or the flow of water over the earth embankment (levee) crown, is a serious threat to the stability of the earth embankment (levee). The danger from overtopping and the necessity for preventive action cannot be over-emphasized. It is very difficult, if not impossible, to close a breach in an earth embankment (levee) after the substantial amount of material has been washed out. The various methods of increasing the height of the earth embankment (levee) to prevent overtopping are described in the following paragraphs. The required height of topping can best be determined by running a line of levels and setting grade stakes, so that a topping grade parallel to a predicted high water profile can be established. A freeboard of about 2-feet above predicted high water is sufficient for determining height of topping.

Sandbag Topping

This method of raising levees may be used when the required additional height is less than 3-feet. It is constructed of layers of earth filled sacks, which form a small berm on the crown of the levee, as shown on Figure 7. The top layer should be at least 3-feet wide and the side slopes should be about 1 on 1, or not less than required to provide a base width sufficient to prevent failure. In no case should the base width be less than three times the height. The landside slopes should be about 1 on 2-1/2 when the topping is placed on a smooth surface, such as concrete or asphalt instead of earth.

The earth levee crown is prepared by stripping the sod to the required width and to within 1-foot of the riverside edge. The surface is then scarified by plowing furrows, or by similar means to a depth of at least 2-inches. A trench should be dug to accommodate a row of sandbags parallel to the axis of the levee. These steps are very important as they provide a good bond between the topping and the levee surface. The sacks are filled two-thirds full of earth, and should be well tramped or tamped into place. They are laid in alternate directions, those in the bottom layer being lengthwise of the levee, the next layer crosswise, etc. Gravel-filled sacks should be placed on the riverside slope of the topping if wave action becomes more severe than anticipated.

Lumber and Sack Topping

This is one of the most common emergency methods of raising low reaches in levees, especially when the height required is less than 3-feet. It is constructed as shown on Figure 8, and consists of a board fence erected on the levee crown about one foot from the riverside edge; backed with sacked earth or earth fill, placed on a surface stripped of sod, and scarified as described in "Sandbag Topping" in Section 9.4. A row of 2 x 4-inch x 6-foot stakes is driven in as straight a line as practicable, to a minimum penetration of 2-feet, 6-inches. The stakes are spaced at 6-foot intervals for boards 12-feet long. A trench for a row of sandbags is dug adjacent to the landward edges of the stakes, with the riverside edge of the bottom being made as level as possible, in order to provide a secure and even seat for the bottom boards of the fence.

The bottom 1 x 12-inch x 12-foot boards are placed firmly on edge, end to end in the trench, and nailed to the stakes. The required additional rows of boards are nailed to the stakes with joints staggered. The fence should be braced as required, with 2 x 4-inch x 10-foot back braces nailed to 2 x 4-inch x 2-foot stakes as shown on Figure 8.

The bottom edge of the fence should be sealed with well-tamped earth fill on the riverside face. The landside backing is usually composed of earth-filled sacks, filled and laid as described in "Sacked Earth or Loose Earth" in Section 9.2 and "Sandbag Topping" in Section 9.4. In some instances, it may be more practical to use tamped earth fill or sack material should be nailed to the landside face of the fence.

Caving Banks and Slides - Temporary Protection - Earth Embankments (Levees)

Caving banks and slides can cause considerable damage and create hazardous conditions which should be remedied immediately upon discovery. Slides, as distinguished from sloughs, are characterized by the shearing of a mass of the embankment on a slip plane. Slides are brought about generally by undercutting due to current scour over a period-of-time. This action is particularly dangerous if the undercutting reaches the base of the earth embankment (levee) proper, which may result in earth embankment (levee) failure. These conditions should be noted and brought to the attention of the Superintendent. As a temporary remedial measure against active caving of river banks, a rock filled crib as illustrated on Figure 1 is very effective when properly placed. This will serve to alleviate bank or levee damage until permanent corrective measures can be taken.

Cribs are usually 14 x 14-feet in plan by 10 to 14-inches in inside depth. The cribs are constructed of a double thickness of 1 x 4-inch x 14-foot lumber, equivalent to 2 x 4-inch pieces, lapped "rail fence" fashion at all corners and intersections. They are divided into four compartments of about equal areas by two perpendicular cross walls constructed in the same manner as the side walls. The floors and covers are built up of double 1 x 4-inch boards spaced about 9-inches center-to-center. Under the floor, and perpendicular to the direction of the floor boards, are five equally spaced pairs of 1 x 4-inch boards about 3-feet center-to-center. On top of the cover, perpendicular to the direction of the cover boards, are three pairs of top boards, one over each of the side walls and one over the central division wall. The compartments are filled with rock before covering. Each wall intersection of the fabricated crib is securely fastened by a loop of No. 9 wire.

Excessive and Pronounced Floodwall Seepage

The possibility that excessive and pronounced seepage may develop in a flood wall section during its life cannot be discounted. It may be due to rodent holes, new basement construction nearby, utility changes, or other unforeseen circumstances. Excessive seepage connected with a wall section is considered more serious than similar seepage at levee sections. It is, therefore, highly desirable that a specific program of patrol and observation of concrete wall sections be established during flood periods. Adequate supplies of emergency treatment materials that may be required for corrective measures should be available. The following measures or combinations may be used in an emergency. (See Figure 9 for illustrations.)

- Stop leakage through joints or small flow channels on riverside of wall by means of cinders, coal dust, sawdust, or other similar materials.
- Where flow entry holes are too large for the treatment outlined above, sink a plastic, canvas, or similar barrier over the hole and place backfill thereon until flow is retarded.
- Place pervious fill (sand and sandbags) over the base area landside of the seepage to restrict flow and to provide additional stability. A blanket of pervious material (bank run gravel or similar material) not less than one foot thick may be placed over the ground surface and confined by sandbags, the height and width as required for stability of the wall. Boil areas beyond the wall limits should be ringed with sandbags as described for levee seepage control.
- Place heavy fill of sandbags over both landside and riverside area of base to weight down wall and restrict movement where it appears that movement may develop.

Flood Wall Extension

The methods for raising concrete walls in emergencies are shown on Figure 10. The wall treatment is similar to the lumber and sack topping for levees described above, in that a board box is built and filled with loose earth, well tamped into place.

Appendix 2

Grand Rapids Flood Protective System
Policies, Procedures, and Inspection Checklist Forms

POLICIES, PROCEDURES, AND INSPECTION REPORT FORMS

FOR

FLOOD PROTECTION WORKS – GRAND RAPIDS, MICHIGAN

1. The City Environmental Services Department has established policies and procedures for the operation of the Water Resource Recovery Facility (WRRF) during emergency conditions inside and outside of the facility. Several of these policies and procedures are directly related to operations during flood conditions in the Grand River. These policies and procedures are included in this appendix.

2. Forms similar to the sample inspection report forms contained herein can be used in submitting reports to the Superintendent who will evaluate the flood protection system condition and ability to protect Grand Rapids from floods on the Grand River. The forms cover inspection, maintenance, and operation of the flood protection works. All information desired and all remarks should be given precisely and accurately. Additional sheets and sketches should be added where necessary to clearly convey the submitted information.

3. Inspection of the features comprising the flood protection system should be made as indicated below.

4. Inspections of the stormwater pump stations should be made annually. Each item of pumping equipment should be trial-operated annually.

5. Earth embankments should be inspected annually through the Office of the City Engineer, immediately following any flood in excess of 31,000 cfs (Stage = 19.34 feet) as measured at the U.S. Geological Survey (USGS) Station 04119000, Grand River at Grand Rapids, Michigan, or at such times deemed necessary by the City Engineer.

6. Periodic detailed inspections and condition evaluations of the floodwalls should be made by the Office of the City Engineer in accordance with the flood protection system asset management plan. The floodwalls shall be visually inspected on an annual basis.

7. An annual report covering inspection, maintenance and operation of the flood protection works should be submitted in April to the City Manager. This report should include all logs of operation and dated copies of all inspection check lists made during the period covered by the reports.

INSPECTION REPORT
FOR
FLOOD PROTECTION WORKS – GRAND RAPIDS, MICHIGAN

SUMMARY OF PUMPING PLANTS

1. **Date of this inspection:** _____
2. **Date of last inspection:** _____

3.

Stormwater Pump Station	Dates of Inspections since last report	Dates of Pumps Operations since last report	Dates of Operation Logs since last report
Market Avenue			
Wealthy Street			
Front - Scribner			
Indian Mill Creek			
Caledonia Street			
Palmer Street			

4. **Unusual occurrences or remarks concerning trial operations and inspections during period covered by this report:** _____
   _____
   _____
   _____
   _____
   _____
5. **Have the key operating personnel been changed? If changes have been made, submit revised list of personnel.**
6. **This inspection revealed the following necessary repairs. (Enclose rough plan of anticipated repair or explain.)** _____
   _____
   _____
   _____
   _____
   _____
7. **At what date (state specific date) will the appropriate City department perform the above repairs?** _____

8. **Remarks and explanations:** _____

_____

_____

No. of additional sheets: _____

Signed _____

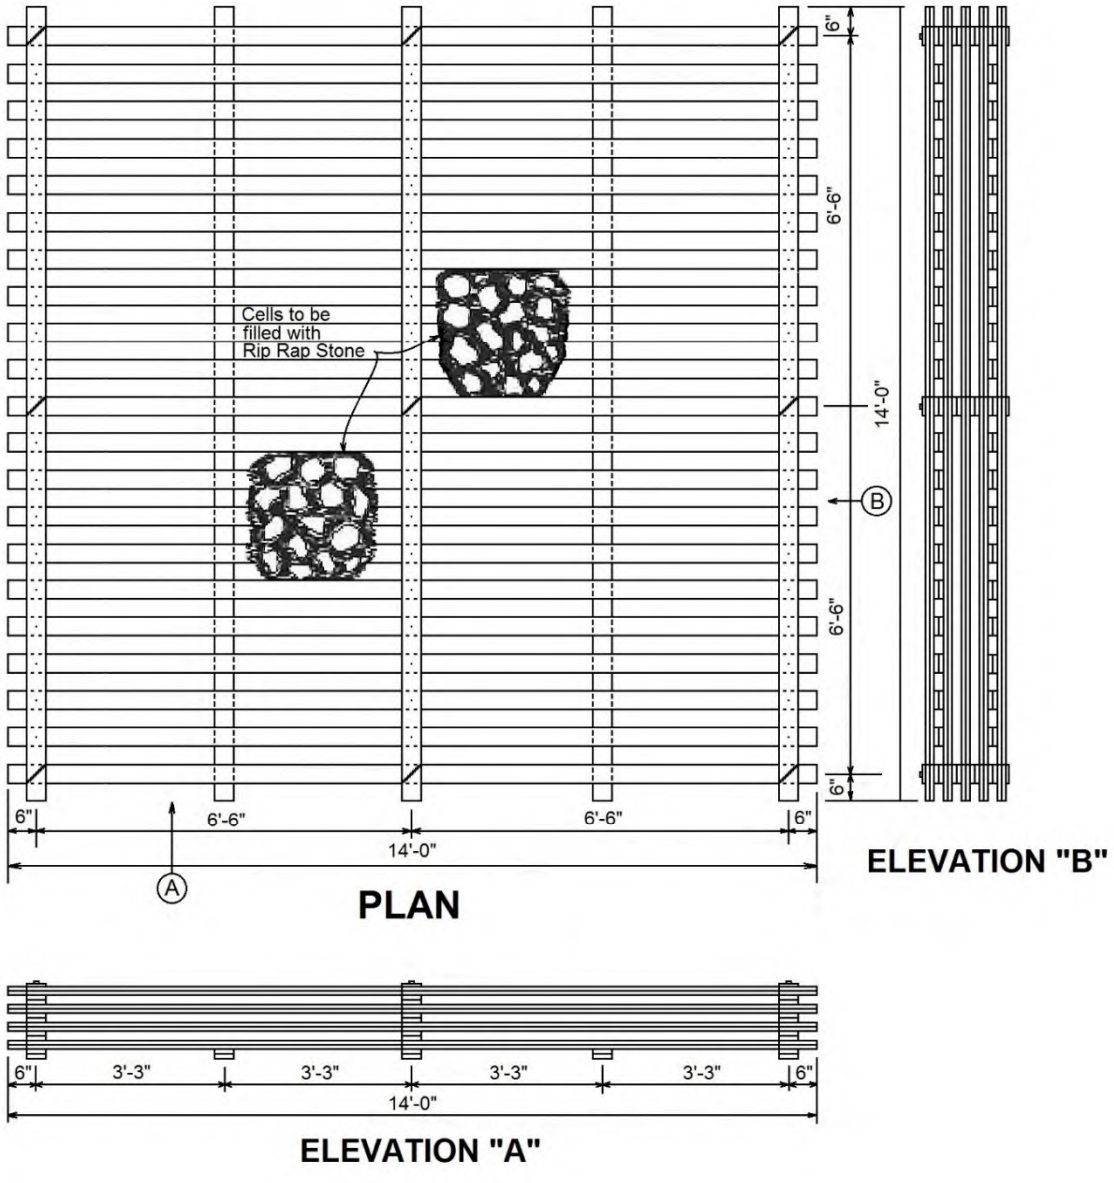
Appendix 3

Grand Rapids Flood Protective System
Figures – Earth Embankment (Levee) and Floodwall Remedial Measures



NOTE:

Cribs constructed of double thicknesses of 1" X 4" X 14' lumber. Nail all intersections with 1-20d. nail. Each intersection of walls securely fastened by a loop of 1/4" strand, tightly twisted. If rock or concrete blocks are unobtainable, sacks filled with gravel or soil cement may be used.

BILL OF MATERIALS

Dimensions based on rough cut lumber

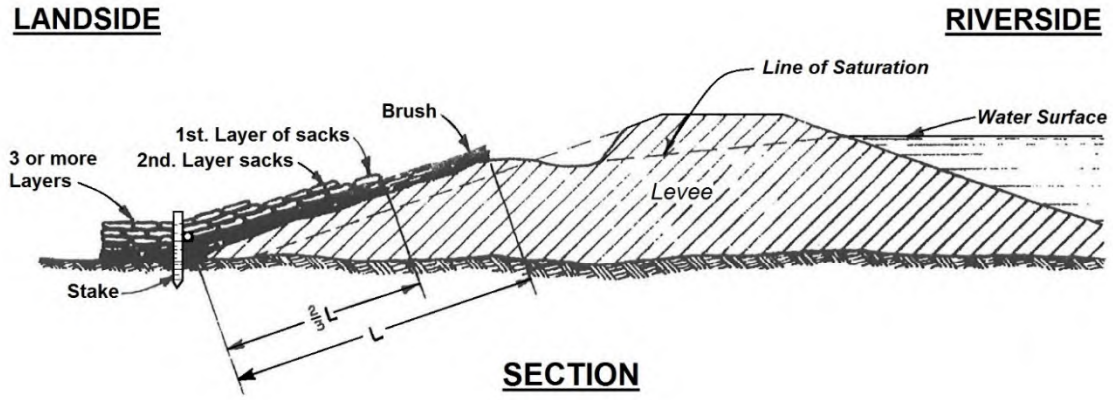
140 Pcs. 1" X 4" X 14' = 653 Bd. Ft.
12 Lbs. 20d. Common Nails
60 Ft. 1/4" Strand
1-1/2 Cu. Yds. Rip Rap Stone
Actual quantities. No allowance for waste.

FIGURE 1

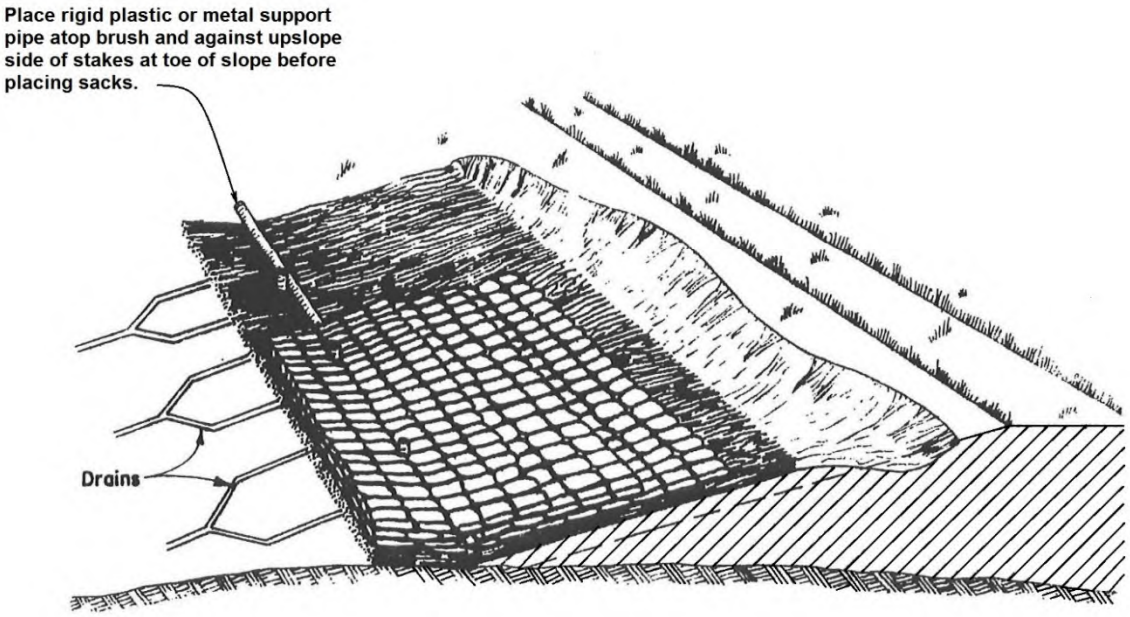
CITY OF GRAND RAPIDS, MICHIGAN

HIGH WATER MAINTENANCE CAVING BANK PROTECTION

ROCK-FILLED CRIB



SECTION

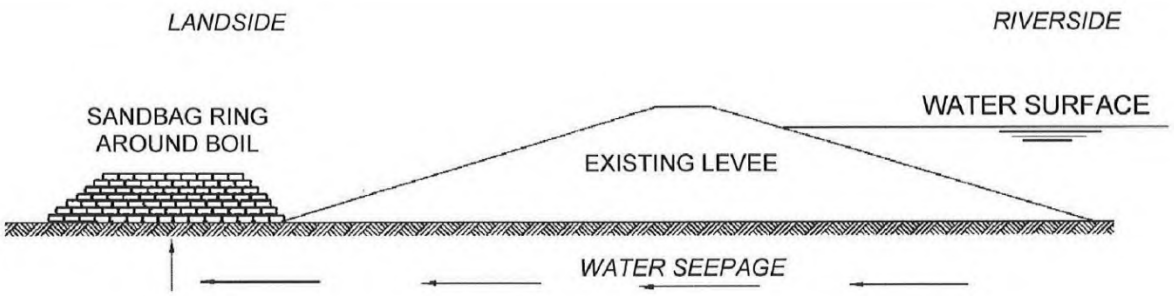


NOTE:
Cut V-Shaped drains no deeper than necessary and not more than 6" deep. Sandbags should be only 2/3 full.

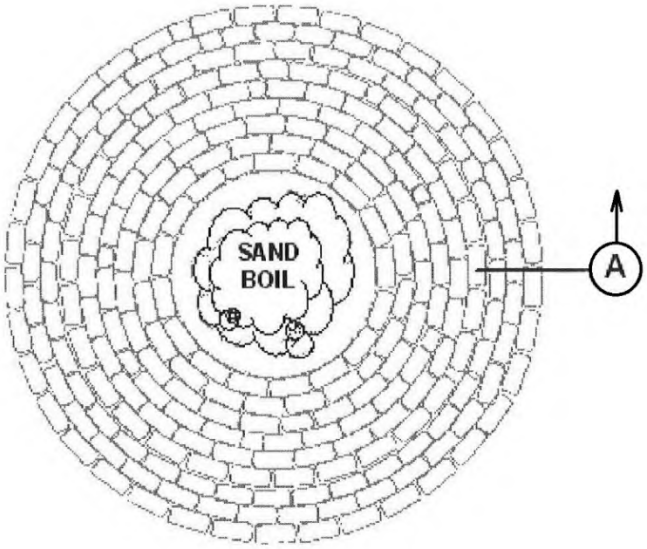
FIGURE 2
CITY OF GRAND RAPIDS, MICHIGAN

HIGH WATER MAINTENANCE
SLOUGHING

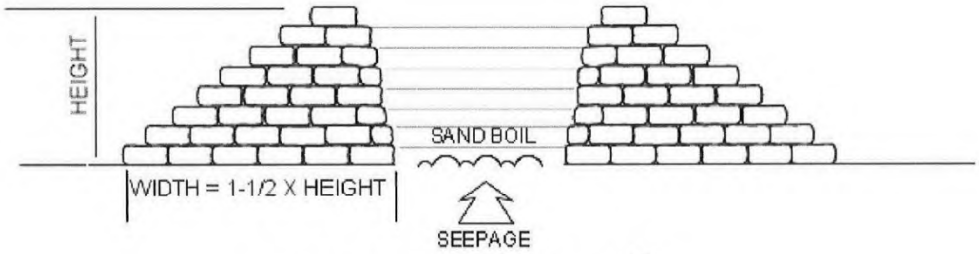
SANDBAG & BRUSH MAT



ELEVATION



PLAN VIEW



SECTIONAL ELEVATION — A

NOTES:

1. Do not sack a boil that does not eject soil material and whose flow is small.
2. Prepare base of sack ring by clearing debris, sod, loose soil or other objectionable material and scarify base.
3. Tamp sand bags into place.
4. Loose soil to be used between all sacks.
5. All sack joints to be staggered.
6. Bottom width to be no less than 1-1/2 times the height. Tie into levee if boil is near toe.
7. Height of sack ring should be only sufficient to create enough head to slow down flow through boil so that no more soil material is displaced and boil runs clear.
8. Never attempt to completely stop flow through boil.
9. Carry off water by omitting one sack in top layer or construct a "V"- shaped drain of boards or sheet metal to protect slope of sack ring.

FIGURE 3

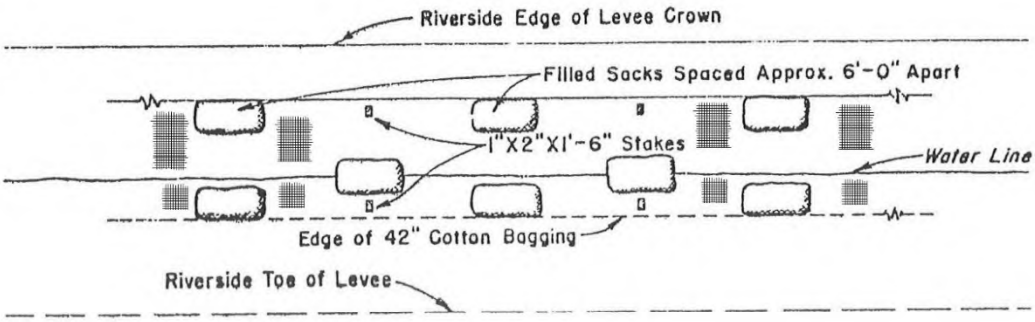
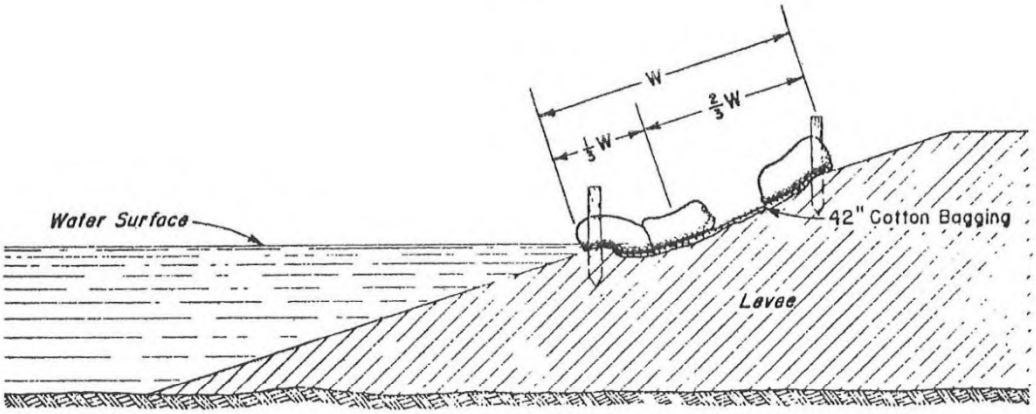
SACKED EARTH RING



PLAN



SECTION

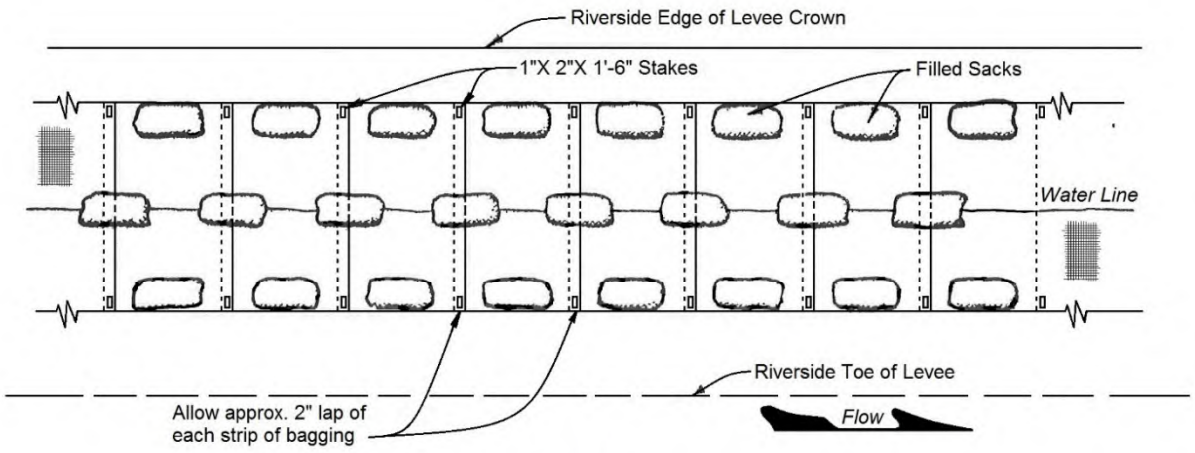
BILL OF MATERIAL TO CONSTRUCT 180 FEET OF PROTECTION		
LUMBER	BAGGING	SANDBAGS
60 - 1"X 2"X 1'-6" Stakes (Sharpened)	One roll regular (jute) Cotton Bagging 42" X 180'- 0"	90 - Filled Sacks

INSTRUCTIONS:
1. Lay 42" cotton bagging (jute) longitudinally along riverside slope of levee with approximate 2/3 width above water surface.
2. Weight bagging along edges and at water surface with filled sacks spaced approximately 6' apart. Drive stakes alternately between sacks along both edges of bagging.
3. If additional width is required, lace two or more widths of bagging together and lay as desired.
4. Plastic sheeting or burlap may be substituted for cotton bagging.

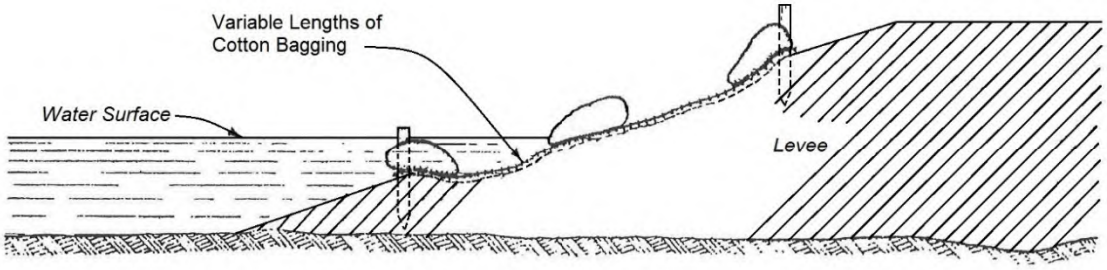
FIGURE 4
CITY OF GRAND RAPIDS, MICHIGAN

HIGH WATER MAINTENANCE
WAVE WASH PROTECTION

SANDBAG & COTTON BAGGING - NO. 1



PLAN



SECTION

Notes:

1. Lay lengths as required of Cotton Bagging approximately parallel with levee slope and across damaged section.
2. Lap strips with river current to prevent lifting.
3. Weight top and edges of bagging with filled sacks as shown above.
4. The filled sacks should be wired or tied to each strip before laying in place.
5. Stake the corners of each strip above the water surface
6. Plastic sheeting or burlap may be substituted for cotton bagging.

BILL OF MATERIAL FOR 100 LINEAR FEET OF LEVEE
LUMBER
120 pieces 1"X 2" x 1'-6" (Sharpened)
SANDBAGS
180 Filled Sacks Cotton Bagging as Required

FIGURE 5

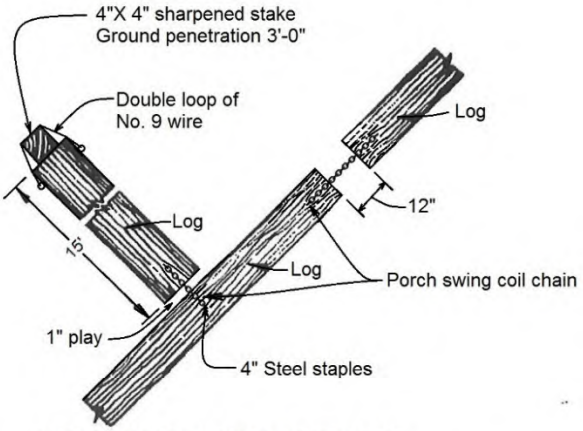
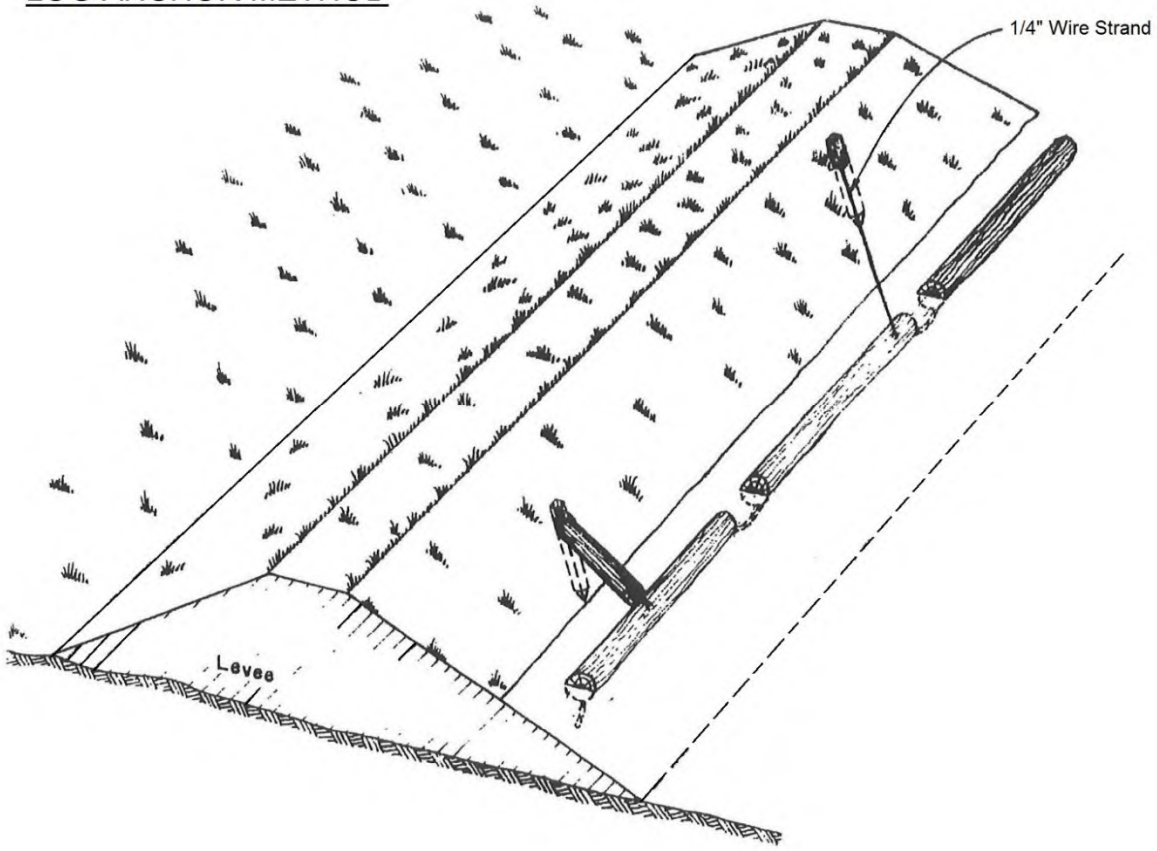
SANDBAG & COTTON BAGGING - NO. 2



LOG ANCHOR METHOD



Notes:
1. Do not drive steel staples all the way in. Staples should protrude sufficiently to allow enough play for rotation of logs.
2. Substitute 3 doubled loops of No. 9 wire if porch swing coil chain is not available.
3. Anchor logs spaced a maximum of 50' apart.

FIGURE 6

Notes:
1. Start upstream.
2. Strip sod before laying.
3. Alternate direction of sacks with bottom layer parallel to flow.
4. Next layer perpendicular to flow with open ends of sacks directed away from wet side.
5. Lap unfilled portion under next sack.
6. Tying of sewing sacks is not necessary.
7. Tamp thoroughly in place. Sacks should be approximately 1/2-full of sand or earth.
8. Width of sack levee should be 3 times the height.

Grand Rapids Flood Protective System
Operations To Be Performed At Various River Stages

Flood Protection System - Operations, Maintenance & Inspection Manual
Operations to be Preformed at Various River Stages

Item No.	Address/Item	Location of Item	Description of Item	Critical Elevation (when problem occurs)		Action Required	Materials Needed (during 100-year event)	Equipment Needed (to deliver and onsite)	Responsible Department
				USGS Flood Stage (at Blue Bridge) 100-year = 25.36	NAVD 88 (at Location of Item)				
1	Storm Water Valve MH castings in Berm at WRRF	**East Side** - WRRF	Two 24" and two 12" storm sewers enter the WWTP from the CSX property to the south. The CSX property is below the the BFE. There are valves on these sewers in the grass embankment between the asphalt drive and perimeter fence. If these valves are open during an extreme flood the WRRF is susceptible to flooding.	19.9	602.0	Close all four valves.	None	2" Square valve key	Environmental Services Department
2*	Underground Tanks at WWRF	East Side - WRRF	Partially filled tanks can become bouyant if groundwater levels are high.	12.0	581.8 groundwater elevation	Check groundwater level around empty or partially empty tanks. Fill tanks as necessary per WWTP O&M Manual.	None	None	Environmental Services Department
3*	Primary Effluent Retention Basin at WWRF	East Side - WRRF	High groundwater levels may exceed the underdrains ability to keep the basin from floating.	12.0	588.8 groundwater elevation	Fill basin to the same elevation and the Grand River level.	None	None	Environmental Services Department
4	East Side Interceptor	**East Side** - Along Eastside of Grand River from MARB to Pearl Street	When the river rises the East Side Interceptor may become bouyant. The pipe is 12' wide and 11.25' tall and is cast-in-place concrete. The invert elevation at the Market Avenue Pump Station is approximately 584.0. The normal water level in the pipe is approximately 24".	12.0	594.5	Keep water level in East Side Interceptor no lower than 15 feet below the Grand River.	None	None	Environmental Services Department
5	240 Front Avenue	**West Side** - Floodwall between Letellier and Emperor Streets (Outfall 83D)	4" core in floodwall for driveway drainage	21.0	604.8	Install 4" inflatable sewer plug.	• 4" inflatable sewer plug = 1 Stored at Wastewater Treatment Plant	Small air compressor	Environmental Services Department
6	242 Front Avenue (Chesapeake & Ohio Railroad)	**West Side** - RR Bridge between Emperor and Butterworth Streets	The top off railroad ballast is slightly below the BFE.	24.5	608.6	Install prefabricated closure.	• prefabricated temporary closure Stored at Wastewater Treatment Plant	Flat bed delivery truck	Environmental Services Department
7*	Fulton/Monroe/Market Avenue Intersection	**East Side** - Fulton/Monroe/Market Avenue Intersection	The area is susceptible to shallow flooding, less than 12 inches in depth, should an extreme rainfall event occur during an extreme flood.	23.5	607.6	Close roads and/or connect portable pumps to quick connect located in chamber outside the curbline at the northeast corner of the intersection and pump water from intersection. (Pump hose to fit Andrews #600B 6" male N.P.T. aluminum quick coupler)	• Sandbags = 3,000 Sand = 28 cyd	• Portable pumps • Flat bed delivery truck • Fork lift	• Traffic Safety Environmental Services Department
8*	Bond Avenue at Newberry Street	**East Side** - Bond Avenue at Newberry Street	The area is susceptible to shallow flooding, less than 12 inches in depth, should an extreme rainfall event occur during an extreme flood.	24.0	612.7	Close roads and/or drain area with portable pumps.	• Sandbags = 3,000 Sand = 28 cyd	Portable pumps	• Street Maintenance Department • Environmental Services Department
9	624 Front Avenue (Fish Ladder Park)	**West Side** - Front Avenue and 4th Street	The sidewalk from the parking lot to the Fishladder is not high enough for extreme flood events.	23.5	611.0	Erect closure by placing aluminum stop logs into guides cast in retaining walls on either side of the sidewalk.	Aluminum stop logs stored at Front Avenue Stormwater Pumping Station	Flat bed delivery truck	Environmental Services Department
10	678 Front Avenue	**West Side** - Floodwall south of 6th Street (Outfalls 109C & 109D)	5" core in floodwall for riverwalk drainage & 4" transformer vault drain.	21.0	609.6	Install 4" & 5" inflatable sewer plugs.	• 4" inflatable sewer plug = 1 • 5" inflatable sewer plug = 1 Stored at Wastewater Treatment Plant	Small air compressor	Environmental Services Department
11*	Myrtle Street from Grand River to Scribner Avenue	**West Side** - Myrtle Street from Grand River to Scribner Avenue	The area is susceptible to shallow flooding, less than 12 inches in depth, should an extreme rainfall event occur during an extreme flood.	20.0	611.0	Close roads and/or drain area with portable pumps.	• Sandbags = 10,000 Sand = 195 cyd	Portable pumps	Environmental Services Department
12*	Jennette Avenue and Silvia Street	**West Side** - Jennette Avenue and Sylvia Street intersection	Shallow flooding occasionally occurs at high Indian Mill Creek flood staeg.	NA	620.8	Close intersection.	• Type 3 Lighted Barricades = 4 • Sandbags = 50 cyd	Flat bed delivery truck	Street Maintenance Department
13*	525 Ann Street	**West Side** - Jeanette Avenue and Sylvia Street intersection.	Trench drain for loading dock	24.5	615.2	Construct 150' of sandbag berm (1' to 1.5')	• Sandbags = 2,250 Sand = 21 cyd	Flat bed delivery truck	Environmental Services Department
14*	2201 & 2401 Monroe Avenue (Riverside Park)	**East Side** - Guild Avenue entrance drive to Riverside Park	The Guild Avenue entrance drive is below the BFE. If river levels area high enough Monroe Avenue will flood between Melbourne Street and 3 Mile. The houses on the eastside of Monroe Avenue in this same stretch are also at risk of flooding, particular homes between Guild Street and Boltwood Drive that have first floors lower than the BFE. These are: 2342 through 2526 Monroe Avenue; 37 Katherine Drive; 28 & 45 Pershing Drive; 64 Parklane Drive; 100 Boltwood Drive.	23.0	614.9	Construct 100' of sandbag berm (0' to 3') across Guild entrance drive.	• Sandbags = 4,500 Sand = 42 cyd	Flat bed delivery truck high low	Environmental Services Department
15*	2201 & 2401 Monroe Avenue (Riverside Park)	**East Side** - Guild Avenue to 3 Mile Road	The existing flood control berm is slightly lower than the BFE. If the river levels are high enough and same issue described in item 15 will result.	23.5	614.4	Construct 3,000' of 2' highh sandbag berm on top of existing berm from Guild to Three Mile.	• Sandbags = 63,000 Sand = 585 cyd	Flat bed delivery truck high low	Environmental Services Department
16*	Elmdale Street @Grand River (Sanitary Lift Station)	**East Side** - Elmdale Street @ Grand River	The river can over to the wetwell. It is also above the level of floor drains or houses contributory to the lift station.	22.0	615.8	If river is over wet well, turn off pumps.	None	None	Environmental Services Department
17*	Elmdale Street @ Grand River	**East Side** - Elmdale Street @ Grand River	This street frequently floods when the Grand River is at flood stage. Also subject to flooding due to sewer surcharging.	16.0	609.5	Close roadways.	• Type 3 Lighted Barricades = 3 • Sandbags = 4 cyd	Flat bed delivery truck	Environmental Services Department

* Flood control measures beyond those required to meet minimum certification requirements; not included in Emergency Action Plan.

KEY NOTES

1. REMOVE SOD AND TOPSOIL FROM NEW GRADING AREA. PLACE FILL TO ACHIEVE NEW ELEVATIONS AS SHOWN. TOP OF BERM = 614. PLACE 4" TOPSOIL AND SOD DISTURBED AREAS.
2. PLACE 4" TOPSOIL AND SEED DISTURBED AREAS.
3. REMOVE EXISTING CONCRETE WALK AND GRAVEL BASE.
4. REMOVE EXISTING PINE TREES.
5. PLACE 6" THICK CONCRETE WALK. SAWCUT 8'x8' SQUARES (MAX)
6. REMOVE AND REINSTALL FENCE AND GUARD RAILING.

SOIL EROSION AND SEDIMENTATION CONTROL

1. SEE SHEET 20 FOR SOIL EROSION AND SEDIMENTATION CONTROL NOTES AND DETAILS.
2. PREDOMINANT SOILS TYPE: URBAN LAND (NRCS WEB SOIL SURVEY)
3. PROXIMITY TO GRAND RIVER: 50 FEET

TITLE: Improvements to Grand River

AS-BUILT 6/2017

DATE: 10.13.16

GENERAL NOTES IBC:

1. The structural design of these removable flood panels has been designed for hydrostatic flood loads with water pressures corresponding to maximum water height as depicted in the enclosed drawings plus hydrodynamic pressure. Free board of 1 foot in ht. is added to the system height of each opening in accordance with the documents listed below in notes 2,3 and 5.
2. It shall be determined, on a job by job basis, the required Panel height and flow speed for the design of Removable Flood Panels, based on FEMA's criteria (See Note #3) as well as per ASCE 24–05 Standard. Installation and construction of these Flood Panels for use within flood hazard areas shall be in accordance with the American Society of Civil Engineers Flood Resistant Design and Construction Standard SEI/ASCE 24–05.
3. Design criteria has been based on the 2012 Edition of the International Building Code, the corresponding provisions of ASCE 24–05, FEMA flood proofing non–residential structures manual FEMA 102, FEMA P–936 dated July, 2013 and FEMA Technical Bulletin 3–93. Design flood loads have been determined in accordance with ASCE 7–10. Design wind loads have been determined in accordance with ASCE 7–10 for 130 mph Basic Wind Speed for category 2 building.
4. Flood Panels shall not be installed within areas where ice flows or ice jams occur.
5. In order to certify flood elevation, Flood Panel design have tested by an independent testing lab for water infiltration in accordance with FEMA 102 manual for flood proofing of non–residential structures, specifications Section 8, Page 70.
6. Flood Panel installer to use gaskets and approved sealants following all the recommendations and specifications of the manufacturers respectively.
7. Owner, General contractor or installer to verify all dimensions, wall and floor conditions at site before proceeding with the work, and shall notify this engineer if any discrepancy is found that would alter the structural design of these Flood Panels.
8. Existing slabs and walls adjacent to opening where Flood Panel is to be installed shall be given a surface treatment by means of water proof sealer before flood Panel is installed. Surface must be smooth, square, plumb and level.
9. Existing slabs and walls adjacent to openings where Flood Panels are to be installed shall be structurally designed by engineer of record, to sustain the same hydrostatic, hydrodynamic and impact pressures that correspond to maximum water elevation above finished floor at top of Panel , based on criteria mentioned on Note #3.
10. Drop–in anchors embedded into concrete for removable support installation shall be covered with a cap or similar device to protect their inside hold from dust, so that machine screws can easily be installed at time of flood warning. Concrete anchors by others.
11. Separation of Panel to window/door shall be measured from back of Panel to window/door including any knob, handle, or protruding device, and shall be 2" minimum.
12. All aluminum extrusions to be 6063–T6 alloy, and 6005–T5 alloy.
13. All sheet metal screws shall be as manufactured by ITW/Buildex "TEK Screws", and to be made of non–corrosive material.
14. All bolts to be galvanized steel ASTM A–307 designation or 304 Series Stainless Steel.
15. All gaskets installed shall be neoprene per drawings.
16. All welding to conform to the American Welding Society AWS D1.2. 1998 Regulations. Use certified welders. Use ER–5356 Electrodes.
17. The engineer, Architecture Metals Ltd. or Flood Panel LLC. is not responsible for construction safety at site which is the owner, general contractor or installer's responsibility. Flood Panel Manufacturer to be responsible for providing the tenant with shop drawings and proper instructions for the installation of these Flood Panels.
18. Surfaces against which the sealing gasket presses must be built "paper–smooth" to prevent excessive water extrusion, beyond that allowed by requirements. All surfaces must be plumb, square and level.
19. To receive a warranty for the flood barriers provided by Flood Panel LLC as depicted in this set of drawings, the following information must be provided by the building owner to Flood Panel LLC:

To receive credit for flood proofing, a completed Flood proofing Certificate for Non–Residential Structures is required for non–residential and business buildings in the Regular Program communities, located in zones A1–A30, AE, AR, AR Dual, AO, AH, and A with BFE.

In order to ensure compliance and provide reasonable assurance that due diligence had been applied in designing and constructing flood proofing measures, the following information must be provided with the completed Flood proofing Certificate:

1. Photographs of shields, gates, barriers, or components designed to provide flood proofing protection to the structure installed and deployed on the building.
2. Written certification that the barrier system was inspected during and after initial installation and is installed per the drawings, engineering and instructions provided by the manufacturer.
3. Written certification that the envelope of the structure is watertight with walls substantially impermeable to the passage of water required under 44 Code of Federal Regulations (44 CFR 60.3 (c)(3))
4. A comprehensive Maintenance Plan for the entire structure to include but not limited to:
   - Exterior envelope of the structure
   - All penetrations to the exterior of the structure
   - All shields, gates, barriers, or components designed to provide flood proofing protection to the structure
   - All seals or gaskets for shields, gates, barriers, or components
   - Location of all shields, gates, barriers, and components as well as all associated hardware, and any
   - Materials or specialized tools necessary to seal the structure.

U.S. DEPARTMENT OF HOMELAND SECURITY
FEDERAL EMERGENCY MANAGEMENT AGENCY
National Flood Insurance Program
NFIP Flood proofing

19. Responsibility for filing the building "Flood Proofing Certificate" is the responsibility of the owner's architect and/or engineer and not of Architecture Metals Ltd. or Flood Panel LLC.

Inflatable Plug Manufacturer's Literature

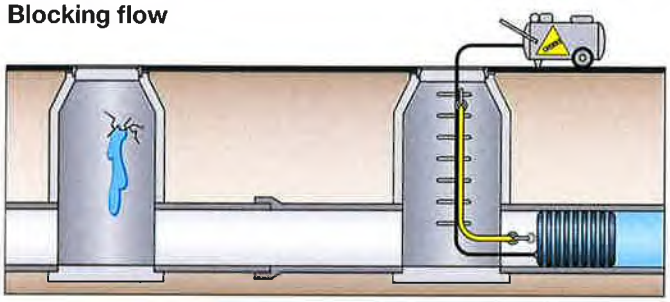
Test Ball® Plugs – Underground

Cherne's Original Single Size and Multi-Size Test Ball Plugs are our most economical pneumatic plugs for blocking flow to do maintenance in sanitary and storm sewer systems. These plugs may also be used as a back plug for sewer air tests.

All of the single-size and multi-size Test Ball plugs have eyebolts for attaching a rope or clevis for lifting and lowering the plug. And each plug also has a removable Schrader valve for easy replacement or substitution with a quick disconnect fitting.

Made from natural rubber, these plugs are tough, tear-resistant and will work on any type of pipe, including out-of-round pipe.

Blocking flow



Single Size Original Test Balls

Part Number	Nominal Size	Usage Range	Maximum Back Pressure		Inflation Pressure	Product Weight	Deflated Length	Deflated Diameter	Inflation Thread	Chain / Eye bolts
041386	8" (200 mm)	7"-8.25" (178-210 mm)	17 psi (1,2 bar)	40 ft. (12 M)	25 psi (1,7 bar)	3.4 lbs (1.6 kg)	10.25" (257 mm)	6.75" (172 mm)	1/4" (1)	3/8" (1)
041394	10" (250 mm)	9"-10.25" (229-260 mm)	17 psi (1,2 bar)	40 ft. (12 M)	25 psi (1,7 bar)	5.6 lbs (2.5 kg)	11.75" (298 mm)	8.75" (221 mm)	1/4" (1)	3/8" (1)
041408	12" (300 mm)	10.5"-12.25" (267-311 mm)	17 psi (1,2 bar)	40 ft. (12 M)	25 psi (1,7 bar)	10.9 lbs (5 kg)	13.75" (351 mm)	10.25" (262 mm)	1/4" (1)	3/8" (1)
041416	15-16" (375-400 mm)	14" - 16.25" (356-413 mm)	13 psi (0,9 bar)	30 ft. (9,1 M)	25 psi (1,7 bar)	29.5 lbs (13.4 kg)	19.75" (502 mm)	13.75" (346 mm)	1/4" (1)	3/8" (2)

Multi-Size Original Test Balls

Part Number	Nominal Size	Usage Range	Maximum Back Pressure		Inflation Pressure	Product Weight	Deflated Length	Deflated Diameter	Inflation Thread	Chain / Eye bolts
275048	4" - 6" (100-150 mm)	3.75"-6.25" (92-159 mm)	17 psi (1,2 bar)	40 ft. (12 M)	30 psi (2,1 bar)	2 lbs (0.91 kg)	9.8" (250 mm)	3.5" (85 mm)	1/8" (1)	1/4" (1)
275058	6" - 8" (150-200 mm)	5.25"-8.25" (135-210 mm)	17 psi (1,2 bar)	40 ft. (12 M)	30 psi (2,1 bar)	3.5 lbs (1.6 kg)	14" (356 mm)	5" (127 mm)	1/4" (1)	3/8" (1)
275088	8" - 12" (200-300 mm)	7"-12.25" (178-311 mm)	11 psi (0,75 bar)	25 ft. (8 M)	20 psi (1,4 bar)	6.63 lbs (3 kg)	16" (406 mm)	6.75" (171 mm)	1/4" (1)	3/8" (1)
275128	12" - 18" (300-450 mm)	10.75"-18.25" (273-464 mm)	11 psi (0,75 bar)	25 ft. (8 M)	25 psi (1,7 bar)	22.4 lbs (10.2 kg)	24" (610 mm)	10.5" (267 mm)	1/4" (1)	3/8" (1)

Always block plugs when conducting air tests.

Appendix 7

CSX RR Bridge Closure Structure

Installation Instructions - CSX Bridge Abutment Closure (Westside of the Grand River)

Existing Conditions
100-Year Flood Elevation = 609.44 (USGS Flood Stage at Blue Bridge = 25.46')
Top of RR Abutment = 608.67 (USGS Flood Stage at Blue Bridge = 24.69')
Unprotected Height = 0.77'
Top of Adjacent Floodwalls = 610.00
Width Between Floodwalls = 38.65'
Temporary Closure Storage Location = GR WWTP (less than 1 mile from site)
Closure includes all materials and fasteners necessary for installation.

Action Level = If USGS Flood Stage at Blue Bridge is predicted to be above 24.50'.

Reference Temporary Closure Drawings 1 through 7 in Appendix 3 of the Closure Evaluation (44 CFR 65.10 (b) (2))

- Contact CSX Bridge and Rail Emergencies at (800) 232-0144
- Remove existing loose railroad tie as shown on Sheet 2; Replace with new 7.2" x 10" x 9'-7" hardwood tie as shown on Sheet 3.
- Shift second existing loose railroad tie to align with abutment face as shown on Sheet 2.
- Place ½" x 8" wide NBR gasket material on top of ties and concrete abutment wall per Sections "A thru F" on Sheet 5.
- Set steel brackets 1, 2 and 3 (Sheet 3) and steel brackets 4, 5, 6 and 7 (Sheet 4) over NBR gasket as shown on Sheet 5.
    - Install ½" x 8" NBR gasket between existing vertical floodwall and steel brackets 1 and 7; See note on Section "A" on Sheet 5.
    - Secure brackets to existing structure (floodwall and ties) per Section "A thru F" on Sheet 5.
- Position the five ½" NBR gasket plates per Sheets 3 and 4 and Section "F" on Sheet 5.
- Position ½" x 4" wide NBR gasket strip as shown on Sections "A thru E" on Sheet 5.
- Install steel stop log 3, NBR gasket plates 2-5 and steel backing plates (Sheet 4) per Section "F" on Sheet 5.
- Install wooden stop logs 1 and 2 (Sheet 3), NBR gasket plate 1, ½" x 4" NBR gasket strip (Sheet 3) per Sections "B thru E" on Sheet 5.
- Install wooden stop log 4 (Sheet 4) and ½" x 4" NBR gasket strips per Sections "B, C and E" on Sheet 5

Installation Instructions - CSX Bridge Abutment Closure (Westside of the Grand River)

Existing Conditions
100-Year Flood Elevation = 609.44 (USGS Flood Stage at Blue Bridge = 25.46')
Top of RR Abutment = 608.67 (USGS Flood Stage at Blue Bridge = 24.69')
Unprotected Height = 0.77'
Top of Adjacent Floodwalls = 610.00
Width Between Floodwalls = 38.65'
Temporary Closure Storage Location = GR WWTP (less than 1 mile from site)
Closure includes all materials and fasteners necessary for installation.

Action Level = If USGS Flood Stage at Blue Bridge is predicted to be above 24.50'.

Reference Temporary Closure Drawings 1 through 7 in Appendix 3 of the Closure Evaluation (44 CFR 65.10 (b) (2))

- Contact CSX Bridge and Rail Emergencies at (800) 232-0144
- Remove existing loose railroad tie as shown on Sheet 2; Replace with new 7.2" x 10" x 9'-7" hardwood tie as shown on Sheet 3.
- Shift second existing loose railroad tie to align with abutment face as shown on Sheet 2.
- Place ½" x 8" wide NBR gasket material on top of ties and concrete abutment wall per Sections "A thru F" on Sheet 5.
- Set steel brackets 1, 2 and 3 (Sheet 3) and steel brackets 4, 5, 6 and 7 (Sheet 4) over NBR gasket as shown on Sheet 5.
    - Install ½" x 8" NBR gasket between existing vertical floodwall and steel brackets 1 and 7; See note on Section "A" on Sheet 5.
    - Secure brackets to existing structure (floodwall and ties) per Section "A thru F" on Sheet 5.
- Position the five ½" NBR gasket plates per Sheets 3 and 4 and Section "F" on Sheet 5.
- Position ½" x 4" wide NBR gasket strip as shown on Sections "A thru E" on Sheet 5.
- Install steel stop log 3, NBR gasket plates 2-5 and steel backing plates (Sheet 4) per Section "F" on Sheet 5.
- Install wooden stop logs 1 and 2 (Sheet 3), NBR gasket plate 1, ½" x 4" NBR gasket strip (Sheet 3) per Sections "B thru E" on Sheet 5.
- Install wooden stop log 4 (Sheet 4) and ½" x 4" NBR gasket strips per Sections "B, C and E" on Sheet 5

Preface

The Grand River Flood Protection System (GRFPS) was constructed along the left and right banks of the Grand River to provide protection for the residents, commercial and institutional establishments, and industries of Walker and Grand Rapids, Michigan from the 100-year return interval flood. The flood protection system was constructed in segments and modified through the years making use of natural stream banks, floodwalls, levees, and road and railroad embankments.

This manual is compiled to assist City of Walker (City) officials in the operation, maintenance and inspection (OM&I) of the GRFPS within the city boundaries including levees and backflow prevention devices. The procedures described in this manual are generally for conditions in the Grand River when the stage, as measured by the U.S. Geological Survey (USGS) gage, upstream of the Fulton Street Bridge in Grand Rapids, is less than 12 feet; however, this manual also provides guidance on flood preparatory measures that may be enacted when flood conditions are predicted to occur. For flood conditions where the stage is above 12 feet and predicted to rise to 18 feet or higher, refer to the GRFPS Emergency Action Plan (EAP).

The successful functioning of the GRFPS is not assured by the mere construction of an adequate system of levees, walls, gates, SPSs, etc. If the GRFPS is to function, it must be carefully maintained throughout normal river stage periods and properly operated during flood periods. Failure to do so can result in severe losses in property and life and may undermine the confidence of the citizens in their reliance on the system. The necessity for proper continuous maintenance cannot be too highly stressed. Considerable damage may be incurred through failure of a minor element of the system at flood times caused by neglect, deterioration, or damage that could have been prevented by proper maintenance. Proper maintenance and operation require that responsible local officials have a thorough understanding of the functions of the various units of the system and the knowledge of best methods of maintaining the system and operating it during flood emergencies. It is with this purpose in mind that this manual has been prepared for the guidance of those responsible for the maintenance and operation of the GRFPS.

Introduction

System Overview

Reach W-1 of the GRFPS is located along the west back of the Grand River in the Cities of Walker and Grand Rapids, Kent County, Michigan. A general plan of the protected area is shown on Figure 11. The protected area in Reach W-1 is approximately 169 acres of which 118 are in the City of Walker, the GRFPS consists of a combination of natural ground and earth embankments built along the banks of the Grand River, which protect approximately 169 acres on the right (west) bank consisting of residential, commercial, institutional, and industrial properties.

Construction History

In Walker, the protective structures consist of earth embankments, flap gates, a short wall and a relief sewer. The construction of the road embankment for U.S. Route 131 occurred in the 1950's when the two-lane State Route M-13, predecessor to U.S. Route 131, was converted into a full freeway. The construction of the I-96 embankments and ramps took place between 1956 and 1962.

The existing storm water collection system serving Turner Avenue discharges to the Grand River at 3 locations. Three small private outfalls also exist. Flow from these pipes discharges to the US-131 drainage system where it is conveyed under US-131 through multiple large culverts. In 2015 six new flap gates were installed on outfalls upstream of the US-131 drainage system to prevent Grand River floodwaters from backing up into Turner Avenue.

In 2016, a relief storm sewer was installed to tie the existing Turner Avenue storm sewer system to storm sewers leading to the Indian Mill Creek Storm Water Pump Station in Grand Rapids. In addition, a short wall was built along US-131 provides approximately once foot of freeboard above the base flood elevation.

Floodplain management regulations are codified in the City of Walker Code of Ordinances, Chapter 42 – Floods and Chapter 67 - Stormwater Management and Control.

Procedures

Purpose

The successful functioning of the GRFPS can be assured by following the procedures set forth in this manual. By doing so, the benefits and protection against floods for which the GRFPS were designed can be secured.

Proper OM&I require that responsible local officials have a thorough understanding of the functions of the various units of the flood protection system; the best methods of maintaining them during normal river stages; and of operating them during flood emergencies. It is with this purpose in mind that this manual has been prepared for the guidance of the City in the OM&I of the GRFPS. This manual assembles and correlates all the details essential for satisfactory OM&I of the flood protection system, so maximum flood protection may be available during the service life of each component of the entire asset.

Duties of the Superintendent

The Superintendent of the flood protection system should be the City Engineer and designated members of his/her support staff. The duties of the Superintendent should include the OM&I oversight, records keeping, and correspondence with the other City officials and departments. The Superintendent should have available the names, addresses, and telephone numbers of all key personnel, and a reasonable number of substitutes. The key personnel should have similar information on all the persons that will be required for assistance in the discharge of their duties. These persons should include the following:

- An assistant to act in the Superintendent's place in cases of his/her absence or indisposition.
- Supervisors in sufficient number to lead maintenance, operation and inspection of the GRFPS. High qualities of leadership and responsibility are necessary for these positions.

The Superintendent should ascertain that key persons have read the portions of the OM&I Manual pertaining to their duties.

The Superintendent should be responsible for the development of an organization capable of providing for the efficient OM&I of the GRFPS, and the necessary maintenance of the entire asset during normal stages of the river.

The provisions of this manual include general requirements that cover practically all types of local flood protection works. They are supplemented by technical data and instructions pertinent to the GRFPS which are necessary for its efficient OM&I.

OM&I Management

The general requirements for the OM&I management of the GRFPS are as follows:

- The structures and facilities should be continually maintained as necessary to obtain the maximum benefits.
- The Superintendent shall be responsible for the efficient OM&I of all the structures and facilities and for routine inspection and maintenance of the entire asset.
- A reserve supply of materials needed during a flood emergency should always be kept on hand.
- No encroachment or trespass which will adversely affect the efficient operation or maintenance of the GRFPS should be permitted upon the rights-of-way for the GRFPS.
- No improvement or construction shall be permitted within the limits of the GRFPS right-of-way, nor should any change be made in any feature of the GRFPS without prior determination by the City Engineer that such improvement, construction, or alteration will not adversely affect the functioning of the GRFPS. Such improvements or alterations, as may be found to be desirable and permissible under the above determination, should be constructed in accordance with standard engineering practice. Record drawings or

prints showing such improvements or alterations as finally constructed should be furnished to the City Engineer after completion of the work.

- At no time should the level of flood protection provided by the GRFPS during construction or any alterations, including excavation, of improvements that pass over, under, or through the GRFPS, be less than that provided for a 100-year flood (1% annual chance of occurrence). All temporary or permanent flood prevention measures made to the GRFPS to facilitate construction must be approved by the City Engineer.
- The City Engineer or authorized representatives should always have access to all portions of the GRFPS.

Permits for Use of Rights-of-Way

The rights-of-way for the GRFPS have been procured and protective works have been constructed thereon for the protection of life and property in times of flood. The Office of the City Engineer provides for the legitimate use of the rights-of-way in addition to crossing by gas lines, oil lines, and utilities, or other use of a similar nature.

A permit from the Michigan Department of Environment, Great Lakes, and Energy (EGLE) may be required for construction along or modifications to the flood protection system under Part 301, Inland Lakes and Streams, of the Natural Resources and Environmental Protection Act (NREPA), 1994 PA 451, as amended. The routine OM&I of the GRFPS is the responsibility of the Department of Public Works, and will be completed in accordance with this manual. The right-of-way for the GRFPS is issued, recorded, and maintained in document form by the Office of the City Engineer.

Adjacent Construction by Others

When owners of properties adjacent to the levees and/or floodwalls initiate new construction, particularly if it involves deep excavation, the City Engineer should be notified and take such action as may be necessary to assure that there is no encroachment on right-of-way, that adequate shoring is used to prevent disturbing flood protection foundations, and that the work insofar as possible is performed outside of flood periods.

River Stage Prediction

It is the responsibility of the City Engineer to keep advised of predicted river stages. This information will enable the City Engineer to make all the necessary preparations required for the operation and erection of those features of the system for the protection of the areas against high river stages in advance of their occurrence.

The river stages referred to herein correspond to automated gage readings taken at the USGS Station 04119000, Grand River at Grand Rapids, Michigan. The gage station is located at latitude 42˚ 57’ 52”, longitude 85˚ 40’ 35” referenced to North American Datum of 1927, in NE 1/4 Section 25, Township 7 N, Range 12 W, Kent County, Michigan, on the right (west) river bank, 500-feet upstream from the Fulton Street bridge in Grand Rapids and 1.7 miles upstream from Plaster Creek. The datum for the gage is 585.70-feet National Geodetic Vertical Datum of 1929 (NGVD 29) (elevation 585.25-feet North American Vertical Datum of 1988 [NAVD 88]). Current river stage information can be obtained from the National Weather Service (NWS) Forecast Office, Grand Rapids, Michigan, Advanced Hydrologic Prediction Service at: http://water.weather.gov/ahps2/hydrograph.php?wfo=grr&gage=gdrm4 or the USGS Michigan Water Science Center at: http://waterdata.usgs.gov/mi/nwis/sw

The predicted stages are available for up to five days in advance. This is sufficient time to allow the City Engineer to make all necessary emergency preparations and conduct such operations as may be required for various river stages as described in this manual and the National Incident Management System (NIMS). It should be kept in mind that the predicted stage is only an approximation and may possibly range higher.

Procedure at Various River Stages

Appendix 4 lists the operations to be performed at various river stages.

The actual time of mobilization of the various personnel will be dependent upon the rate of rise of the Grand River (see "Grand River – Rate of Rise – Closure Operation" in Emergency Closure Structures), the various functions to be performed, the condition of the flood protection system, the time required to erect sandbag and other closures, and other pertinent requirements of the Special Operation & Maintenance During High Water Periods section of this manual.

Reference Drawings

A list of reference drawings including record drawings is included in Appendix 1. The station references used in this manual are referenced to a survey baseline along the centerline of the Grand River that begins at Station (Sta.) 2003+05.20, at the right lane edge of pavement on the east bound lanes of the Interstate 196 (I-196) bridge. The survey baseline station numbers increase in the upstream direction.

Elevations

The GRFPS was constructed at different times under different construction contracts. Therefore, different vertical datums were used throughout the history of construction. To the extent possible, the elevation datum for all elevations used in this manual are identified in its paragraphs. The user of this manual should be careful to discern which vertical datum is being used when comparing to published flood elevations. The conversion between elevations using the NAVD 88 and those using NGVD 29 is given by:

NAVD 88 = NGVD 29 – 0.4495 feet

Safety

The Superintendent should provide a health and safety plan in accordance with the Occupational Safety and Health Administration law and regulations for all personnel involved in the maintenance of the GRFPS. The Superintendent and maintenance personnel should familiarize themselves with the safety procedures and implement them during routine maintenance and flood operations. Safety precautions should be complied with as follows:

- Personnel should remain alert to the possibility of hazardous gases at the structures, primarily at the manholes and junction chambers, and take appropriate safety measures when inspecting, maintaining, or operating the structures.
- Two persons should always be present during maintenance, inspection, or operation of all drainage structures. The buddy system should be used to provide necessary help and assistance to each other in the event an accident occurs.
- Since a potential drowning hazard exists during flood emergencies, emergency response teams from the City's Fire Department with appropriate personnel and equipment shall respond accordingly.

Inspections

Annual inspections of the portion of the GRFPS within Walker will be completed by the Department of Public Works, or their consultants. Repair and maintenance of the GRFPS should be completed as soon as possible under the direction of the City Engineer.

Earth Embankments (LEVEES)

Earth Embankment Maintenance

The pertinent requirements for maintenance of the earth embankments are as follows:

The City Engineer shall provide for maintenance as may be required to insure serviceability of the earth embankments in time of flood. Measures should be taken to promote the growth of sod, exterminate or remove burrowing animals, and to provide for routine mowing of the grass and weeds, removal of wild growth and drift deposits, and repair of damage caused by erosion or other forces. Where practicable, measures should be taken to retard bank erosion by placement of riprap stone or by planting suitable plants on areas riverward of the levees. Inspection of the earth embankment should be completed by the City Engineer, or designee, to ensure the above maintenance measures are being effectively carried out and to be certain that:

- No unusual settlement, sloughing, or material loss of grade or earth embankment cross section has taken place.
- No caving has occurred on either the land side or the river side of the earth embankment which might affect the stability of the earth embankment section.
- No seepage, saturated areas, or sand boils are occurring.
- Toe drainage systems are in good working condition and that such facilities are not becoming clogged.
- Drains through the earth embankments and backflow gates on said drains are in good working condition.
- No revetment work or riprap has been displaced, washed out, or removed.
- No action is being taken, such as burning grass and weeds during inappropriate seasons, which will retard or destroy the growth of sod.
- Access roads to and on the earth embankments are being properly maintained.
- Crown of the earth embankment is shaped to drain readily and roadway, if any, is well shaped and maintained.
- There is no unauthorized vehicular traffic on the earth embankment.
- Encroachments are not being made on the earth embankment right-of-way which might endanger the structure or hinder its proper and efficient functioning during times of emergency.

Burrowing Animals

Burrowing animals (muskrats and groundhogs) create seepage paths in earth embankments. Burrowing animals should be removed from the earth embankment and the burrows filled with a mud-pack prepared by adding water to a 90 percent soil and 10 percent cement mixture until a slurry or thin cement consistency is attained. After filling the burrow with the mud pack mixture, the burrow entrance should be filled with dry earth and seeded.

Drift

Drift (river-borne debris) should be removed from the earth embankment and other grassed areas on the right-of-way at the end of each winter flood season before the new growth of grass starts in the spring, and after each flood occurring during the growing season.

Gullies, Holes, and Washes

Gullies, holes, and washes in the levee, slopes, and berms should be repaired using compacted clay soils in an approved manner.

Earth Embankments Crest Depressions

Gaps occurring where trail or road crossings have been worn down or where the earth embankment may be below grade should be remedied. It is advisable to run levels occasionally to determine whether depressions have occurred in the top of the earth embankment. The profile of the top of the earth embankment should be maintained to the elevations shown on the construction plans.

Spare Cover Vegetation

All areas deficient in sod should be reseeded or resodded.

Seeding

When new permanent seeding is necessary to obtain cover for bare areas, it is recommended that such work be done in the late summer, between July 15 and September 15, or in the spring between April 10 and June 5. Temporary seeding can be performed up to a month before or a month after the above dates, respectively; however, temporary seeding must be followed-up with permanent seeding during the appropriate season.

Sodding

Where sodding is considered the most favorable method of reestablishing a good stand of grass on the earth embankment, it should be performed in advance of the flood season to ensure knitting of the transplanted sod with the prepared base. Sodding should preferably be done between May 1 and October 20, if irrigation can be provided as needed. Sod should not be laid between June 10 and September 10 without irrigation.

Grass Mowing

Grass should be mowed as necessary to help maintain a good stand of grass.

Earth Embankment (Levee) Inspection

Sample check list forms for use in performing inspections of earth embankments (levees) are included in Appendix 2.

Earth Embankment (Levee) Operation

When the Grand River flood stage exceeds 12 feet at the USGS gauge station, the earth embankment should be patrolled daily, or more frequently as conditions warrant, to locate possible sand boils or unusual wetness of the landward slope and to be certain that:

- There are no indications of slides or sloughs developing.
- Wave wash or scouring action is not occurring.
- No low reaches of earth embankment exist that may be overtopped.
- No other conditions exist which might endanger the structure as determined by the City Engineer.

Earth Embankment Damage Due to High Water:

If it is found that sand boils, scouring, or other hazardous conditions are occurring, immediate steps should be taken to control the situation and repair or correct any damage. In the face of such dangerous conditions due to high water, the provisions of the NIMS shall be implemented. Suggested methods of operations for combating such flood conditions are given in the Special Operation & Maintenance During High Water Periods section of this manual.

Sand Boils and Seepage Areas:

When sand boils or other seepage areas are observed which are of small magnitude, posing no major threat to structure safety, and therefore are not economically feasible to repair, their locations should be recorded for future action.

Drainage Structures

Maintenance

Under the classification of drainage structures include: culverts, manholes, storm sewers, and flap gates. The various backflow prevention measures on the pipe penetrations through the GRFPS with outfalls below the Base Flood Elevation (BFE) are described in detail in the Closure Analysis Report.

Adequate measures should be taken to ensure that inlet and outlet channels are kept open and that trash, or debris is not allowed to accumulate near drainage structures. Flap gates on drainage structures should be examined, lubricated, and operated annually. Periodic inspections should be made by the Superintendent to be certain that:

- Pipes, riprap, and headwalls are in good conditions.
- Inlet and outlet channels are open.
- Care is being exercised to prevent the accumulation of trash and debris near the structures, and that no fires are being built near bituminous coated pipes.
- Erosion is not occurring adjacent to the structure which might endanger its water tightness or stability.

Immediate steps will be taken to repair damage, replace missing or broken parts, or remedy adverse conditions disclosed by such inspections.

In addition, there are flap gates on the outlets of the storm drains at the locations listed in Table 1. Note that all the gates in the following tables are flap gates unless otherwise noted.

Table 1 – Drainage Structures West Side of Grand River				
River Station	Outfall No.	Facility ID No.	Pipe Size & Material	Flap Gate Location
2257+00	135-B1	2084177	36" RCP	At riverside toe of embankment for U.S. Route 131 and at head of channel draining to river north of Ann Street, NW
2268+00	135-C1	*	12" RCP	On end of pipe in drainage swale on west side of U.S. Route 131 at rear of and between 2204 Turner Avenue, NW and 2280 Turner Avenue, NW
2273+00	135-C2	*	12" RCP	On end of pipe in drainage swale on west side of U.S. Route 131 at rear of and between 2280 Turner Avenue, NW and 2356 Turner Avenue, NW

Pipe Material Key RCP = reinforced concrete pipe

The flap gates should be operated, serviced, and lubricated annually to be certain that they swing freely and do not bind. Clear all debris that prevents full closing of the flap gate. Caution: To prevent possible damage, do not allow the flaps to slam against their seats.

Inspection

Drainage structures should be inspected annually. Sample inspection check list forms are provided in Appendix 2.

Operation

Whenever a flood stage exceeding 18 feet as measured at the USGS Station 04119000, Grand River at Grand Rapids, Michigan, is predicted by the NWS Forecast Office, Advanced Hydrologic Prediction Service (see Permits for Use of Rights-of-Way section), all gates should be inspected before water reaches the invert of the pipe and any object which might prevent closure of the gate should be removed. All drainage structures in earth embankments (levees) should be inspected frequently during floods to ascertain whether seepage is taking place along the lines of their contact with the embankment. Immediate steps should be taken to correct any adverse condition.

Flap Gate Operation Caution

Observe cautions for operating the flap gates as directed in the maintenance instructions.

Flap Gate Operation

The flap gates should be inspected in order that objects that would prevent the gate from seating properly or sealing may be removed. The flap gates should be closely monitored until it is determined that they are securely closed and that no more debris will pass through their outlets. Water will pass through a flap gate outlet when the landside water surface is above the riverside water surface. Until both surfaces are above the crown of the pipe, floating debris and trash will attempt to pass through the drainage structure and can possibly keep the gate from seating properly when the water on the riverside reaches an elevation above that on the landside.

Emergency Closure Structures

Maintenance

When the flap gates on the drainage structures fail to close or leak excessively during a flood, emergency closure structures will be required. Emergency closures consist of either sewer plugs or other closures. The sewer plugs and other closures should be inspected annually to be certain that:

- Proper closure can be made promptly when necessary (no obstructions are found in the area where the closure would be installed that would obstruct installation).
- Sufficient materials and supplies are on hand for the placement of sewer plugs and other closures (e.g. sandbags, lumber, wire, etc.) and that the location of such materials and supplies will be readily accessible in times of emergency.
- Sewer plugs are clean and free of leaks, bulges, cracks, or other damage that would prevent proper installation.

Inspection

The other closures and sewer plugs should be inspected annually. Sample inspection check list forms are provided in Appendix 2. The forms contain an inventory of materials necessary for the complete erection and operation of the closures. All materials should be checked against the check list to ascertain their presence at the City storage location. It is advisable to check the material storage areas immediately before impending high water to see that no materials are missing. Any irregularities observed during inspections should be noted and immediate measures taken to correct them.

Operation

The closing of flow paths for flood waters should be started in sufficient time to permit full closure before flood waters flow into the protected areas. The closures will be inspected frequently during flood periods to ascertain that no undue leaking is occurring and that drains provided to care for ordinary leakage are functioning properly.

Closures and Sewer Plug Closing

The sewer plug and other closures should be installed as instructed in the Special Operation & Maintenance During High Water Periods section of this manual. The installation of closures require labor crews, backhoes, dump trucks, and experienced supervisors to minimize the time involved to complete the closures. The sandbags, filled approximately two-thirds full of earth, are laid with ends not tied and with joints staggered. The untied end is lapped under the adjacent sack. Each layer of sacks should be laid in alternate directions. The riverside face should have a batter of approximately 1 on 1, and the landside slope should be approximately 1 on 2-1/2, with the width of sacking at the top of the levee being 3-feet. The installation of sewer plugs requires experienced crews with portable air compressors and pneumatic hoses.

Grand River - Rate of Rise - Closure Operation

It is imperative that ample time be allowed to install the closures before the water reaches the predicted flood elevation. It is the responsibility of the Superintendent to keep advised of predicted river stages and of possible additional local rainfall. This information will enable the Superintendent to make all the necessary preparations required for the erection of those features of the system for the protection of the area against high river stages in advance of their occurrence. River stage predictions for the Grand River and forecasts of local rainfall are issued by the NWS, Advanced Hydrologic Prediction Service, NOAA, Grand Rapids Michigan, at the internet web site: http://water.weather.gov/ahps2/hydrograph.php?wfo=grr&gage=gdrm4

With this information, it will be possible to perform such operations as may be required for various stages. The predicted stages are usually available five days in advance. This is sufficient time to allow the Superintendent to make all necessary emergency preparations. Due consideration must be given to the rate of rise of the river. Table 2 contains Rates of Rise in feet per hour for various gage readings up to flood crest of major flood experiences. By comparing a predicted flood with records of past floods (Table 2), it is possible to estimate and use as a guide Rates of Rise to be expected at various gage readings over the period required to effect closure. There are many factors determining the Rates of Rise, and the City Engineer shall be consulted in understanding the predictability of the Grand River and the Rates of Rise that may be anticipated. The period required to install each closure must also consider the possible delays because of inexperienced help and other delays.

NOTES:

(1) Action stage - River is bank full upstream and downstream of floodwalls in downtown Grand Rapids.

Clean Up

Upon final recession of flood waters, the sandbags and other closures should be disassembled and emptied of sand into stockpiles. All closures should be inspected, repaired or replaced, as required, and restored to appropriate storage locations. Sewer plugs should be deflated, removed from the pipes, and inspected for damage and leaks. All damaged and unsalvageable materials should be removed and disposed.

Special O&M During High Water Periods

General

This section of the manual is supplementary in nature and describes standard practices that have been used to advantage on levees and floodwalls during high-water emergencies. Most of the methods described herein have been developed during years of experience with the various problems that arise during periods of high water, but they are not intended to restrict the Superintendent, or others concerned, to a rigid set of rules for every possible circumstance. In all cases, the Superintendent should follow standard engineering practices in meeting emergency situations.

Earth Embankment (Levee) System

The earth embankment system may be subjected to certain dangers during flood periods from current, ice, debris, or wave action. These dangers diminish with the degree of maintenance that the earth embankment system receives during normal river stages. Properly constructed earth embankments (levees), if adequately maintained, should withstand any major flood. However, certain unexpected conditions that arise during floods and threaten the earth embankment (levee) system may be met with assurance if prompt action is taken and proper methods of treatment are used. Measures to cope with sand boils, seepage, sloughs, wave wash, ice impact or jams, scour, and possible overtopping of neglected low spots in the earth embankments (levees) and floodwalls, are described herein. Prompt and adequate maintenance will result in minimizing the necessity for such measures during high water periods.

Preparedness

It will be noted in the following paragraphs that various materials and equipment are required to combat such unforeseen conditions as may arise during a flood emergency. It is imperative to know in advance just where such materials and equipment may be secured in emergencies, even though such emergencies may never arise. A definite plan should be prepared by the Superintendent that will enable him to foresee just what materials he will need, where they may be obtained in time for use, what manpower and transportation will be needed, what routes will be open at particular river stages, etc. This information will be particularly vital as the possibility of earth embankment (levee) and/or floodwall overtopping is approached. Such a plan, once formed, must be checked prior to each flood season since the sources of material supply could very likely change during the year. The essential element in a flood emergency is time, therefore local interests should give early attention to the preparation of a list of sources from which the necessary labor, lumber, hardware, sandbags, suitable earth for sacking, equipment, etc., can readily be secured to cover any contingency. Such items should be provided as rapidly as is possible when the need arises.

Materials

For all practical purposes, the materials of consequence used during flood emergencies are:

Sandbags.

- Lumber (rough, common pine)
- Sacked or loose earth
- Plastic tarps/sheets
- Wire (No. 9) and nails

A reserve supply of emergency materials should be kept on hand or be immediately available through arrangements with local suppliers or manufacturers. The principal consideration in obtaining lumber and other materials for emergency construction is their availability. Stored materials subject to damage or deterioration should be checked, and damaged portions replaced, before the start of each high-water season.

Sacked Earth or Loose Earth

Sacks filled with earth can be used in almost every phase of emergency high water work. It may best be used when the point of placement is readily accessible by truck. It is advisable to use sacked earth under other conditions. Sacks should be filled about two-thirds full, with the material shaken down into the sack loosely (never tamped). Sacks need not be tied or sewn together at the top if used for capping or on the land side of the earth embankment (levee). Earth-filled sacks used for wave wash, or as weights, should be filled and the ends tied. Sand should be used only if earth is not available, or if the time element is an important factor as in the distance required for hauling. In some cases, it may be better to fill sacks elsewhere and haul them to the site.

Sandbags

The term "sandbags" as used in flood emergency construction might to be considered a misnomer in that the bags are ordinarily filled with earth. Sand is used only when they are used as weights or when earth availability is a problem. An adequate initial supply of sandbags should be maintained to make all necessary sandbag closures. Bags must be checked annually to detect any deterioration. They should be stored in a dry location where there is free passage of air around them to prevent spontaneous combustion. Any bags that are damp, wet, or oily, should not be returned to storage with the main supply. Sacks used for sandbags are mildew treated burlap or ultraviolet light-resistant polypropylene. When they are two-thirds full, they hold about one-third cubic foot of earth. Any type and suitable size sack can be used if burlap or polypropylene is not available.

Earth

The most suitable type of earth to be used for flood emergency construction is a silty loam or a silty clay loam; however, almost any available soil can be used with plastic tarps/sheets to provide a waterproof barrier or liner.

Preliminary Preparations

The City should have a trained organization, who may readily be assembled by the Superintendent immediately upon receipt of information that a Grand River flood stage > 12' is forecast. This organization should be capable of quick expansion so that sufficient personnel are available to complete the necessary work. As his/her initial activity, the Supervisor should make a detailed inspection, particularly with reference to the following matters:

- Condition of earth embankments (levees and recent repairs)
- Condition of drainage structures
- Transportation facilities; roads, rail, and traffic/rail control signals
- Material supply; quantity, location, and condition
- Communications; verify that phones to be used by emergency personnel are operational

Initial Work

After initial inspection, the Supervisor should perform the following work immediately where required. To accomplish such work, he/she should have organized labor and obtained the supplies and equipment as may be necessary.

- Where new earth embankment (levee) construction has been performed on the riverside of earth embankment (levee), preparation should be made in advance to combat wave wash by facing with sandbags.
- Inspect all flap gates, before the seats are submerged, to ascertain that they are clear of obstructions and will seat properly.
- Ascertain that all roads to and along the earth embankments (levees) are in good condition. The Superintendent should obtain the assistance of the local road forces to have all necessary roads put in usable condition. The Superintendent should be informed at all times of all roads in the vicinity that are closed for

repair. An up-to-date route layout should be available at all times showing routes over which any and all types and weights of equipment can be sent to any point in the protection system.

- Locate necessary tools and materials (sacks, sandbags, lumber, lights, etc.), and distribute and store them at points where active maintenance is anticipated.
- Check and repair of all telephones necessary for operation; obtain lists of all team forces, bus, automobile, and truck transportation that can be made available.
- Make thorough arrangements with reliable citizens of the community for supply, transportation, subsistence, and shelter for the necessary labor.
- Investigate all drainage ditches on the landside of the earth embankments (levees) and open these drains when obstructions exist.

Methods of Treatment – General

After the above preliminary organizations and precautions have been completed, the various methods of combating possible flood emergencies are ready to be employed. Temporary treatment of emergency situations is described in the following paragraphs.

Seepage - Earth Embankments (Levees)

Seepage emerging from the slope, or at the landside toe of an earth (levee) embankment, can cause sloughing of the slope or even lead to piping (internal erosion) of fine sand or silt material. In many cases, high water stages do not act against the earth embankment (levee) long enough for this to happen, but the possibility of the combination of high water and a period of heavy precipitation may bring this about. To prevent sloughing where the slope is deeply saturated, small V-shaped drains should be cut in the landside slope to remove the seepage water. If the earth embankment (levee) should become saturated over a relatively large area, it may become necessary to take the measures outlined below to prevent sloughing.

Slope Drainage - Earth Embankments (Levees)

Drainage of the slope should be provided at all places on the landside of the earth embankment (levee) where seepage appears. The drains should be V-shaped, no deeper than necessary, and never more than 6-inches deep. The sod should not be cut unnecessarily. In all instances, drains should be cut straight down the earth embankment (levee) slope. Where possible near the toe of the slope, the small drains should be Y'd together and lead into large drains which lead to ponding areas or SPSs.

Sloughing - Earth Embankments (Levees)

Sloughing is the slipping, or flowing out of position, or the landside slope of an earth embankment (levee), due to being saturated through seepage to the point where that part of the earth embankment (levee) becomes unstable. Reaches in the earth embankment (levee), where the material is of such nature that prolonged high stages may cause sloughing, should be thoroughly drained as described above. After this operation, a single layer of willow brush, if obtainable, or any small trees or limbs, should be laid up and down the slope, butts upward and tops downward, and weighted with earth-fill sacks. If the slope begins to slough down, a log or heavy timber should be laid on top of the willows at the toe of the material sloughed off and fastened to long stakes which have been driven several feet into the ground. A buttress of earth filled sacks should then be built at the toe and extended up the slope. The buttress at the toe should be built in the shape of a small berm. Sandbags or weights should not be placed more than two-thirds of the distance from the toe of the material sloughed off to the bottom of the slough. See Figure 2.

Sand Boils - Earth Embankments (Levees)

A sand boil is a definite stream of seepage water issuing from the earth, usually near the landside toe of an earth embankment (levee). The source of this water is usually from pervious materials underlying the earth embankment (levee) or floodwall. Sand boils are serious in any location and should be watched closely, especially when within 100-feet of the earth embankment (levee) toe. A sand boil which discharges clear water in a small steady flow, is ordinarily not a serious threat to the safety of the earth embankment (levee) or floodwall, and need not be ringed. However, if the flow increases or carries a substantial load of sand and silt, corrective action should be taken immediately to prevent possible earth embankment (levee) failure. A neglected sand boil may gradually undermine an earth embankment (levee) and cause failure by subsidence of the levee.

The accepted method of treating a sand boil is to construct a watertight ring of sand bags around the boil, high enough to create a head of water within the ring sufficient to reduce the velocity of flow. See Figure 3. The ring should not be built to a height which stops the flow of water completely. The sacks are filled about two-thirds full of earth, and are laid flat in a ring around the boil with the joints staggered, each layer being placed in alternate directions. The sacks should be lapped at least one-third. The ends are left untied, and are lapped under the sacks. Each complete layer should be tramped or tamped into place after placement. The base width of the ring should be not less than one and one-half times, and preferably twice, the contemplated height. A drain is provided by omitting one bag in the top layer, or by constructing a V-shaped drain of two boards or a piece of sheet metal inserted near the top of the ring.

If ground weakness is indicated close to the sand boil, it is well to include the weak ground within the ring, thereby avoiding the possibility of a breakthrough later. Several sand boils within a relatively small radius should be enclosed as a group in a sub-levee or single sack ring. Sand boils at the toe of the levee or floodwall are sacked in the same manner as those away from the earth embankment (levee), and in the case of an earth embankment (levee), using the earth embankment (levee) slope as one side of the closure.

Sandbags, Cotton Bagging, or Plastic Sheeting

Sections of cotton bagging or plastic sheeting should be placed over the washed areas as shown on Figure 4. If the washed area is considerable, or protection is desired to a predicted higher stage, the bagging may be cut into lengths and laid up and down the slope to cover the area. The strips should be lapped with the current to prevent lifting. See Figure 5. Bagging must be thoroughly weighted down with stone or sandbags to be effective. In using this method, stakes should be driven through the bagging approximately 6-feet apart below the water surface and at the top of protection, to be sure that the bagging is being held in place. As an alternative, sacked earth material may be used as a means to fill small washed areas or holes. The sacks should be placed close together beginning about 2-feet under the water surface. Each succeeding row of sacks should overlap the preceding row like shingles on a roof. The joints should be staggered. All holes should be filled with sufficient sacked earth to meet the original grade line. All sacks should be tamped into place so that wave action will not readily wash them away.

Log Boom

If sacking for the prevention of washes caused by floating ice cannot be placed or used effectively, it is desirable to make a log boom of any available large timbers to deflect ice from the embankment. The logs should be fastened together with steel staples and coil chain, or heavy wire, with a distance of about 12-inches between end faces. The staples at each end of the log should be driven on a line parallel to the axis of the log, and should be allowed to protrude sufficiently to permit enough room for rotation of the logs. Wire or chain should be passed or wrapped around the logs as staples may pull out. The boom should be strung along the levee slope and anchored about 15-feet out from the water's edge by means of logs or timbers, spaced not more than 50-feet apart, tied to stakes near the shoreline. See Figure 6. The booms should also be anchored to the slope approximately every 200-feet, or as conditions may require, with cables placed at angles of about 45 degrees.

Additional stakes can be driven up the levee slope in anticipation of a rising river, and the anchor logs and cable ties adjusted as required. This method of protection is particularly effective against ice flows.

Scour

Current scour, or erosion of the riverside slope of the levee, is caused by abnormally high current velocities. Conditions which could cause scour may be detected by the appearance of eddies and general turbulence of the water. Immediate steps should be taken to protect the levee when current scour appears.

Overtopping - Earth Embankment (Levee)

Overtopping, or the flow of water over the earth embankment (levee) crown, is a serious threat to the stability of the earth embankment (levee). The danger from overtopping and the necessity for preventive action cannot be over-emphasized. It is very difficult, if not impossible, to close a breach in an earth embankment (levee) after the substantial amount of material has been washed out. The various methods of increasing the height of the earth embankment (levee) to prevent overtopping are described in the following paragraphs. The required height of topping can best be determined by running a line of levels and setting grade stakes, so that a topping grade parallel to a predicted high-water profile can be established. A freeboard of about 2-feet above predicted high water is sufficient for determining height of topping.

Sandbag Topping

This method of raising levees may be used when the required additional height is less than 3-feet. It is constructed of layers of earth filled sacks, which form a small berm on the crown of the levee, as shown on Figure 7. The top layer should be at least 3-feet wide and the side slopes should be about 1 on 1, or not less than required to provide a base width sufficient to prevent failure. In no case should the base width be less than three times the height. The landside slopes should be about 1 on 2-1/2 when the topping is placed on a smooth surface, such as concrete or asphalt instead of earth.

The earth levee crown is prepared by stripping the sod to the required width and to within 1-foot of the riverside edge. The surface is then scarified by plowing furrows, or by similar means to a depth of at least 2-inches. A trench should be dug to accommodate a row of sandbags parallel to the axis of the levee. These steps are very important as they provide a good bond between the topping and the levee surface. The sacks are filled two-thirds full of earth, and should be well tramped or tamped into place. They are laid in alternate directions, those in the bottom layer being lengthwise of the levee, the next layer crosswise, etc. Gravel-filled sacks should be placed on the riverside slope of the topping if wave action becomes more severe than anticipated.

Lumber and Sack Topping

This is one of the most common emergency methods of raising low reaches in levees, especially when the height required is less than 3-feet. It is constructed as shown on Figure 8, and consists of a board fence erected on the levee crown about one foot from the riverside edge; backed with sacked earth or earth fill, placed on a surface stripped of sod, and scarified as described in ”Sandbag Topping” in Section 9.4. A row of 2 x 4-inch x 6-foot stakes is driven in as straight a line as practicable, to a minimum penetration of 2-feet, 6-inches. The stakes are spaced at 6-foot intervals for boards 12-feet long. A trench for a row of sandbags is dug adjacent to the landward edges of the stakes, with the riverside edge of the bottom being made as level as possible, in order to provide a secure and even seat for the bottom boards of the fence.

The bottom 1 x 12-inch x 12-foot boards are placed firmly on edge, end to end in the trench, and nailed to the stakes. The required additional rows of boards are nailed to the stakes with joints staggered. The fence should be braced as required, with 2 x 4-inch x 10-foot back braces nailed to 2 x 4-inch x 2-foot stakes as shown on Figure 8.

The bottom edge of the fence should be sealed with well-tamped earth fill on the riverside face. The landside backing is usually composed of earth-filled sacks, filled and laid as described in “Sacked Earth or Loose Earth” in

Section 9.2 and “Sandbag Topping” in Section 9.4. In some instances, it may be more practical to use tamped earth fill or sack material should be nailed to the landside face of the fence.

Caving Banks and Slides - Temporary Protection - Earth Embankments (Levees)

Caving banks and slides can cause considerable damage and create hazardous conditions which should be remedied immediately upon discovery. Slides, as distinguished from sloughs, are characterized by the shearing of a mass of the embankment on a slip plane. Slides are brought about generally by undercutting due to current scour over a period-of-time. This action is particularly dangerous if the undercutting reaches the base of the earth embankment (levee) proper, which may result in earth embankment (levee) failure. These conditions should be noted and brought to the attention of the Superintendent. As a temporary remedial measure against active caving of riverbanks, a rock filled crib as illustrated on Figure 1 is very effective when properly placed. This will serve to alleviate bank or levee damage until permanent corrective measures can be taken.

Cribs are usually 14 x 14-feet in plan by 10 to 14-inches in inside depth. The cribs are constructed of a double thickness of 1 x 4-inch x 14-foot lumber, equivalent to 2 x 4-inch pieces, lapped “rail fence” fashion at all corners and intersections. They are divided into four compartments of about equal areas by two perpendicular cross walls constructed in the same manner as the side walls. The floors and covers are built up of double 1 x 4-inch boards spaced about 9-inches center-to-center. Under the floor, and perpendicular to the direction of the floor boards, are five equally spaced pairs of 1 x 4-inch boards about 3-feet center-to-center. On top of the cover, perpendicular to the direction of the cover boards, are three pairs of top boards, one over each of the side walls and one over the central division wall. The compartments are filled with rock before covering. Each wall intersection of the fabricated crib is securely fastened by a loop of No. 9 wire.

GRAND RAPIDS FLOOD PROTECTION SYSTEM POLICIES, PROCEDURES, AND INSPECTION CHECKLIST FORMS

POLICIES, PROCEDURES, AND INSPECTION REPORT FORMS

FOR

FLOOD PROTECTION WORKS – WALKER, MICHIGAN

1. Forms similar to the sample inspection report forms contained herein can be used in submitting reports to the Superintendent who will evaluate the flood protection system condition and ability to protect Walker from floods on the Grand River. The forms cover inspection, maintenance, and operation of the flood protection works. All information desired and all remarks should be given precisely and accurately. Additional sheets and sketches should be added where necessary to clearly convey the submitted information.

2. Inspection of the features comprising the flood protection system should be made as indicated below.

3. Earth embankments should be inspected annually through the Office of the City Engineer, immediately following any flood in excess of 31,000 cfs (Stage = 19.34 feet) as measured at the U.S. Geological Survey (USGS) Station 04119000, Grand River at Grand Rapids, Michigan, or at such times deemed necessary by the City Engineer.

4. An annual report covering inspection, maintenance and operation of the flood protection works should be submitted in April to the City Manager. This report should include all logs of operation and dated copies of all inspection check lists made during the period covered by the reports.

SECTIONAL ELEVATION — A

NOTES:

1. Do not sack a boil that does not eject soil material and whose flow is small.
2. Prepare base of sack ring by clearing debris, sod, loose soil or other objectionable material and scarify base.
3. Tamp sand bags into place.
4. Loose soil to be used between all sacks.
5. All sack joints to be staggered.
6. Bottom width to be no less than 1-1/2 times the height. Tie into levee if boil is near toe.
7. Height of sack ring should be only sufficient to create enough head to slow down flow through boil so that no more soil material is displaced and boil runs clear.
8. Never attempt to completely stop flow through boil.
9. Carry off water by omitting one sack in top layer or construct a "V"- shaped drain of boards or sheet metal to protect slope of sack ring.

60 - 1"X 2"X 1'-6" Stakes (Sharpened)	One roll regular (jute) Cotton Bagging 42" X 180'- 0"	90 - Filled Sacks

INSTRUCTIONS:
1. Lay 42" cotton bagging (jute) longitudinally along riverside slope of levee with approximate 2/3 width above water surface.
2. Weight bagging along edges and at water surface with filled sacks spaced approximately 6' apart. Drive stakes alternately between sacks along both edges of bagging.
3. If additional width is required, lace two or more widths of bagging together and lay as desired.
4. Plastic sheeting or burlap may be substituted for cotton bagging.

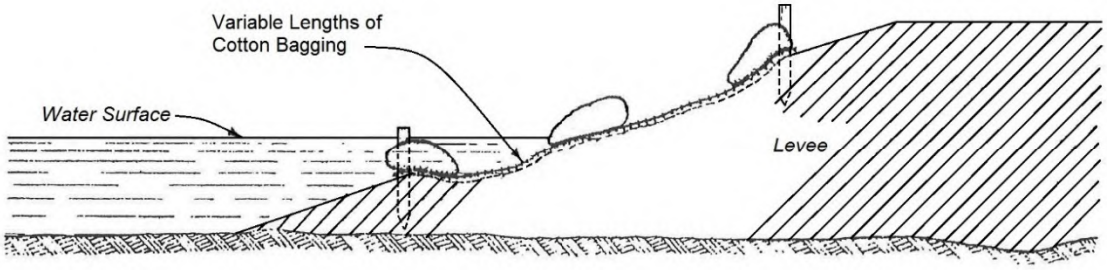
PLAN



SECTION

Notes:

1. Lay lengths as required of Cotton Bagging approximately parallel with levee slope and across damaged section.
2. Lap strips with river current to prevent lifting.
3. Weight top and edges of bagging with filled sacks as shown above.
4. The filled sacks should be wired or tied to each strip before laying in place.
5. Stake the corners of each strip above the water surface
6. Plastic sheeting or burlap may be substituted for cotton bagging.

FLOOD PROTECTION EASEMENT

DBV Partners, L.L.C., a Michigan limited liability company, of 1946 Turner Ave. NW, Grand Rapids, MI 49504 (the "Grantor"), in exchange for payment of $1.00, the receipt of which is acknowledged, quit-claims to the **City of Grand Rapids**, a Michigan municipal corporation, with offices at 300 Monroe Ave. NW, Grand Rapids, MI 49503 (the "City") a permanent easement in, on, over, under, and through the area described and depicted in the attached Exhibit B (the "Flood Protection Easement Area") for the purposes of surveying, designing, constructing, inspecting, repairing, replacing, improving, maintaining, altering, rehabilitating, monitoring, removing, using, and operating a floodwall, embankment, or other flood protection infrastructure, together with storm sewers or drains, flap gates, backflow preventers and other appurtenances thereto, subject to the following terms and conditions of this Flood Protection Easement (this "Easement"):

1. The City, including its officers, employees, contractors, engineers and other agents, shall have the right of ingress to and egress from the Flood Protection Easement Area through the Grantor's larger parcel described on the attached Exhibit A (the "Grantor's Property"), and any accretions thereto, over a route prearranged with the then property owner, in order to access the Flood Protection Easement Area for the purposes for which this Easement is provided. The then property owner shall not unreasonably delay, hinder, or condition such access or other City rights provided in this paragraph. Except in cases of an emergency, the City shall provide the then property owner (according to the City Assessor's property tax records) reasonable written notice of the City's intention to exercise its rights under this paragraph.

2. Upon the completion of any work performed pursuant to the City's rights under this Easement, the remainder of the Grantor's Property shall, to the extent it is damaged or disturbed by the work undertaken pursuant to this Easement, be restored to substantially the same condition it was in prior to such work at no cost to the Grantor or the then property owner.

3. The Grantor, its successors and assigns shall not and shall not suffer or permit any others to alter any improvements made or work performed pursuant to this Easement within the Flood Protection Easement Area. The Grantor, its successors and assigns shall not and shall not suffer or permit any others to construct, operate or maintain within the Flood Protection Easement Area any structure, except that which existed prior to the date of this Easement or improvements or additions to such an existing structure built in accordance with then applicable laws, ordinances, codes, rules or regulations, or structures or uses to which the City first consents in a written instrument recorded with the Kent County Register of Deeds.

4. Neither the Grantor nor the City (including their respective successors or assigns) shall grant an easement within the Flood Protection Easement Area to any other person or entity for any purpose, including, without limitation, any utility, without the prior consent of the other party to this Easement in a written instrument recorded with the Kent County Register of Deeds. However, the City, in its sole discretion, may assign this Easement or some or all of its rights, duties and obligations under this Easement to one or more parties who are engaged in providing some or all of the benefits to the general public as described in this Easement.

5. This Easement shall be perpetual and shall be binding upon the Grantor's successors, grantees, assigns, heirs and anyone else who may obtain an interest in the Grantor's Property from or through the Grantor.

6. The consent of Grantor's mortgagee is attached to this Easement.

The Grantor signed this Easement as of this 28th day of November, 2016.

FLOOD PROTECTION EASEMENT

DBV Partners, L.L.C., a Michigan limited liability company, of 1946 Turner Ave. NW, Grand Rapids, MI 49504 (the "Grantor"), in exchange for payment of $1.00, the receipt of which is acknowledged, quit-claims to the **City of Grand Rapids**, a Michigan municipal corporation, with offices at 300 Monroe Ave. NW, Grand Rapids, MI 49503 (the "City") a permanent easement in, on, over, under, and through the area described and depicted in the attached Exhibit B (the "Flood Protection Easement Area") for the purposes of surveying, designing, constructing, inspecting, repairing, replacing, improving, maintaining, altering, rehabilitating, monitoring, removing, using, and operating a floodwall, embankment, or other flood protection infrastructure, together with storm sewers or drains, flap gates, backflow preventers and other appurtenances thereto, subject to the following terms and conditions of this Flood Protection Easement (this "Easement"):

1. The City, including its officers, employees, contractors, engineers and other agents, shall have the right of ingress to and egress from the Flood Protection Easement Area through the Grantor's larger parcel described on the attached Exhibit A (the "Grantor's Property"), and any accretions thereto, over a route prearranged with the then property owner, in order to access the Flood Protection Easement Area for the purposes for which this Easement is provided. The then property owner shall not unreasonably delay, hinder, or condition such access or other City rights provided in this paragraph. Except in cases of an emergency, the City shall provide the then property owner (according to the City Assessor's property tax records) reasonable written notice of the City's intention to exercise its rights under this paragraph.

2. Upon the completion of any work performed pursuant to the City's rights under this Easement, the remainder of the Grantor's Property shall, to the extent it is damaged or disturbed by the work undertaken pursuant to this Easement, be restored to substantially the same condition it was in prior to such work at no cost to the Grantor or the then property owner.

3. The Grantor, its successors and assigns shall not and shall not suffer or permit any others to alter any improvements made or work performed pursuant to this Easement within the Flood Protection Easement Area. The Grantor, its successors and assigns shall not and shall not suffer or permit any others to construct, operate or maintain within the Flood Protection Easement Area any structure, except that which existed prior to the date of this Easement or improvements or additions to such an existing structure built in accordance with then applicable laws, ordinances, codes, rules or regulations, or structures or uses to which the City first consents in a written instrument recorded with the Kent County Register of Deeds.

4. Neither the Grantor nor the City (including their respective successors or assigns) shall grant an easement within the Flood Protection Easement Area to any other person or entity for any purpose, including, without limitation, any utility, without the prior consent of the other party to this Easement in a written instrument recorded with the Kent County Register of Deeds. However, the City, in its sole discretion, may assign this Easement or some or all of its rights, duties and obligations under this Easement to one or more parties who are engaged in providing some or all of the benefits to the general public as described in this Easement.

5. This Easement shall be perpetual and shall be binding upon the Grantor's successors, grantees, assigns, heirs and anyone else who may obtain an interest in the Grantor's Property from or through the Grantor.

6. The consent of Grantor's mortgagee is attached to this Easement.

The Grantor signed this Easement as of this 28th day of November, 2016.

MORTGAGEE'S CONSENT TO FLOOD PROTECTION EASEMENT

The undersigned, Mercantile Bank Mortgage Company, LLC, of 310 Leonard St. NW, Grand Rapids MI 49501 (the "Lender"), being the mortgagee under that certain Mortgage dated October 27, 2011, recorded on October 31, 2011 as Instrument No. 20111102-0087183, Kent County Records, and assignee under that certain Assignment of Rents dated October 27, 2011, recorded on October 31, 2011 as Instrument No. 20111102-0087184, Kent County Records (collectively, the "Mortgage"), hereby consents to the granting of the Flood Protection Easement to which this Consent is attached (the "Easement") between DBV Partners, L.L.C., as grantor, and the City of Grand Rapids, a Michigan municipal corporation (the "City"), as grantee. The undersigned agrees that even though the Mortgage is prior in time to the interest of the City under the Easement, it and its successors and assigns shall recognize the rights of the City, its successors and assigns under the Easement. No foreclosure of the Mortgage or sale of the property or deed in lieu of foreclosure shall terminate the Easement or otherwise cut off or extinguish any of the City's easement rights under the Easement.

FLOOD PROTECTION EASEMENT

DBV Partners, L.L.C., a Michigan limited liability company, of 1946 Turner Ave. NW, Grand Rapids, MI 49504 (the "Grantor"), in exchange for payment of $1.00, the receipt of which is acknowledged, quit-claims to the **City of Grand Rapids**, a Michigan municipal corporation, with offices at 300 Monroe Ave. NW, Grand Rapids, MI 49503 (the "City") a permanent easement in, on, over, under, and through the area described and depicted in the attached Exhibit B (the "Flood Protection Easement Area") for the purposes of surveying, designing, constructing, inspecting, repairing, replacing, improving, maintaining, altering, rehabilitating, monitoring, removing, using, and operating a floodwall, embankment, or other flood protection infrastructure, together with storm sewers or drains, flap gates, backflow preventers and other appurtenances thereto, subject to the following terms and conditions of this Flood Protection Easement (this "Easement"):

1. The City, including its officers, employees, contractors, engineers and other agents, shall have the right of ingress to and egress from the Flood Protection Easement Area through the Grantor's larger parcel described on the attached Exhibit A (the "Grantor's Property"), and any accretions thereto, over a route prearranged with the then property owner, in order to access the Flood Protection Easement Area for the purposes for which this Easement is provided. The then property owner shall not unreasonably delay, hinder, or condition such access or other City rights provided in this paragraph. Except in cases of an emergency, the City shall provide the then property owner (according to the City Assessor's property tax records) reasonable written notice of the City's intention to exercise its rights under this paragraph.

2. Upon the completion of any work performed pursuant to the City's rights under this Easement, the remainder of the Grantor's Property shall, to the extent it is damaged or disturbed by the work undertaken pursuant to this Easement, be restored to substantially the same condition it was in prior to such work at no cost to the Grantor or the then property owner.

3. The Grantor, its successors and assigns shall not and shall not suffer or permit any others to alter any improvements made or work performed pursuant to this Easement within the Flood Protection Easement Area. The Grantor, its successors and assigns shall not and shall not suffer or permit any others to construct, operate or maintain within the Flood Protection Easement Area any structure, except that which existed prior to the date of this Easement or improvements or additions to such an existing structure built in accordance with then applicable laws, ordinances, codes, rules or regulations, or structures or uses to which the City first consents in a written instrument recorded with the Kent County Register of Deeds.

4. Neither the Grantor nor the City (including their respective successors or assigns) shall grant an easement within the Flood Protection Easement Area to any other person or entity for any purpose, including, without limitation, any utility, without the prior consent of the other party to this Easement in a written instrument recorded with the Kent County Register of Deeds. However, the City, in its sole discretion, may assign this Easement or some or all of its rights, duties and obligations under this Easement to one or more parties who are engaged in providing some or all of the benefits to the general public as described in this Easement.

5. This Easement shall be perpetual and shall be binding upon the Grantor's successors, grantees, assigns, heirs and anyone else who may obtain an interest in the Grantor's Property from or through the Grantor.

6. The consent of Grantor's mortgagee is attached to this Easement.

The Grantor signed this Easement as of this 28th day of November, 2016.

CALL 811 FOR MISS DIG

FOR PROTECTION OF UNDERGROUND UTILITIES AND IN CONFORMANCE WITH PUBLIC ACT 53, 1974, THE CONTRACTOR SHALL CALL 811 A MINIMUM OF THREE (3) FULL WORKING DAYS (EXCLUDING SATURDAYS, SUNDAYS AND HOLIDAYS) PRIOR TO EXCAVATING IN THE VICINITY OF UTILITY LINES. ALL "MISS DIG" PARTICIPATING MEMBERS WILL THUS BE ROUTINELY NOTIFIED. THIS DOES NOT RELIEVE THE CONTRACTOR OF THE RESPONSIBILITY OF NOTIFYING UTILITY OWNERS WHO MAY NOT BE A PART OF THE "MISS DIG" ALERT SYSTEM.

GENERAL NOTES

1) MATERIALS AND WORKMANSHIP SHALL BE IN ACCORDANCE WITH THE 1993 EDITION OF THE CITY OF GRAND RAPIDS STANDARD CONSTRUCTION SPECIFICATIONS, EXCEPT AS OTHERWISE INDICATED ON THESE PLANS OR IN THE SUPPLEMENTAL SPECIAL SPECIFICATIONS.

THE UNDERGROUND LOCATIONS SHOWN FOR NATURAL GAS (GAS), TELEPHONE (TEL), ELECTRICAL POWER (PWR), CABLE TV (CTV) AND FIBER OPTIC LINES (FIBER) ARE APPROXIMATE. THE CITY OF GRAND RAPIDS ASSUMES NO RESPONSIBILITY FOR THEIR ACCURATE REPRESENTATION IN THIS DRAWING. MISS DIG MUST BE CONTACTED PRIOR TO CONSTRUCTION TO LOCATE THESE UTILITIES.

CALL 811 FOR MISS DIG

FOR PROTECTION OF UNDERGROUND UTILITIES AND IN CONFORMANCE WITH PUBLIC ACT 53, 1974, THE CONTRACTOR SHALL CALL 811 A MINIMUM OF THREE (3) FULL WORKING DAYS (EXCLUDING SATURDAYS, SUNDAYS AND HOLIDAYS) PRIOR TO EXCAVATING IN THE VICINITY OF UTILITY LINES. ALL "MISS DIG" PARTICIPATING MEMBERS WILL THUS BE ROUTINELY NOTIFIED. THIS DOES NOT RELIEVE THE CONTRACTOR OF THE RESPONSIBILITY OF NOTIFYING UTILITY OWNERS WHO MAY NOT BE A PART OF THE "MISS DIG" ALERT SYSTEM.

GENERAL NOTES

1) MATERIALS AND WORKMANSHIP SHALL BE IN ACCORDANCE WITH THE 1993 EDITION OF THE CITY OF GRAND RAPIDS STANDARD CONSTRUCTION SPECIFICATIONS, EXCEPT AS OTHERWISE INDICATED ON THESE PLANS OR IN THE SUPPLEMENTAL SPECIAL SPECIFICATIONS.

THE UNDERGROUND LOCATIONS SHOWN FOR NATURAL GAS (GAS), TELEPHONE (TEL), ELECTRICAL POWER (PWR), CABLE TV (CTV) AND FIBER OPTIC LINES (FIBER) ARE APPROXIMATE. THE CITY OF GRAND RAPIDS ASSUMES NO RESPONSIBILITY FOR THEIR ACCURATE REPRESENTATION IN THIS DRAWING. MISS DIG MUST BE CONTACTED PRIOR TO CONSTRUCTION TO LOCATE THESE UTILITIES.

NOTICE OF AUTHORIZATION

Permit Number: WRP043093 v.1 **Date Issued: December 20, 2024**
Site Name: 41-220 Front Ave NW-Grand Rapids **Expiration Date: December 20, 2029**

The Michigan Department of Environment, Great Lakes, and Energy (EGLE), Water Resources Division, P.O. Box 30458, Lansing, Michigan 48909-7958, under provisions of the Natural Resources and Environmental Protection Act, 1994 PA 451, as amended; specifically:

☒ Part 31, Floodplain Regulatory Authority of the Water Resources Protection.

☒ Part 301, Inland Lakes and Streams.

☒ Part 303, Wetlands Protection.

Authorized activity:

Removal of four (4) low-head dams and construction of several in-stream rock structures in the Grand River for the purposes of restoring rapids, improving public safety, improving habitat, and enhancing access and use. The proposed work would permanently impact approximately 2,750 linear feet of the Grand River channel by dredging approximately 14,244 cubic yards of material and placing approximately 32,110 cubic yards of fill below the Ordinary High-Water Mark (OHWM). The project would permanently impact the 100-year floodplain (El. 612.0 FT NAVD 88) of the Grand River by dredging approximately 1,448 cubic yards of material and placing approximately 724 cubic yards of fill within the floodplain and floodway. The proposed work would also permanently impact 0.01 acres emergent wetlands by dredging approximately 61 cubic yards of material and placing 73 cubic yards of fill within existing wetland areas.

To be conducted at property located in: Kent County, Waterbody: Grand River
Section 24, Town 07N, Range 12W, City of Grand Rapids

Permittee:
Tim Burkman
300 Monroe Avenue Northwest
City of Grand Rapids - Engineering Department
Grand Rapids, Michigan 49503

Lucas A. Trumble, P.E.
Dam Safety Unit
Water Resources Division
517-420-8923

This notice must be displayed at the site of work.
Laminating this notice or utilizing sheet protectors is recommended.
Please refer to the above permit number with any questions or concerns.

Expires On:12/20/2029

MICHIGAN DEPARTMENT OF ENVIRONMENT, GREAT LAKES, AND ENERGY
WATER RESOURCES DIVISION
PERMIT

Issued To:

Tim Burkman
300 Monroe Avenue Northwest
Engineering Department
Grand Rapids, Michigan 49503

Permit No: **WRP043093 v.1**
Submission No.: **HQ2-Y2FM-WS9TA**
Site Name: **41-220 Front Ave NW-Grand Rapids**
Issued: **December 20, 2024**
Revised:
Expires: **December 20, 2029**

This permit is being issued by the Michigan Department of Environment, Great Lakes, and Energy (EGLE), Water Resources Division, under the provisions of the Natural Resources and Environmental Protection Act, 1994 PA 451, as amended (NREPA); specifically:

- ☒ **Part 301, Inland Lakes and Streams**
- ☒ **Part 303, Wetlands Protection**
- ☐ **Part 315, Dam Safety**
- ☒ **Part 31, Water Resources Protection (Floodplain Regulatory Authority)**
- ☐ **Part 323, Shorelands Protection and Management**
- ☐ **Part 325, Great Lakes Submerged Lands**
- ☐ **Part 353, Sand Dunes Protection and Management**

EGLE certifies that the activities authorized under this permit are in compliance with the State Coastal Zone Management Program and certifies without conditions under the Federal Clean Water Act, Section 401 that the discharge from the activities authorized under this permit will comply with Michigan's water quality requirements in Part 31, Water Resources Protection, of the NREPA and associated administrative rules, where applicable.

Permission is hereby granted, based on permittee assurance of adherence to State of Michigan requirements and permit conditions, to:

Authorized Activity:

Removal of four (4) low-head dams and construction of several in-stream rock structures in the Grand River for the purposes of restoring rapids, improving public safety, improving habitat, and enhancing access and use. The proposed work would permanently impact approximately 2,750 linear feet of the Grand River channel by dredging approximately 14,244 cubic yards of material and placing approximately 33,107 cubic yards of fill below the Ordinary High-Water Mark (OHWM). The project would permanently impact the 100-year floodplain (El. 612.0 FT NAVD 88) of the Grand River by dredging approximately 1,448 cubic yards of material and

EGLE

placing approximately 724 cubic yards of fill within the floodplain and floodway. The proposed work would also permanently impact 0.01 acres emergent wetlands by dredging approximately 61 cubic yards of material and placing 73 cubic yards of fill within existing wetland areas.

Waterbody Affected: Grand River
Property Location: Kent County, City of Grand Rapids Township, Town 07N, Range 12W, Section 24

Authority granted by this permit is subject to the following limitations:

A. Initiation of any work on the permitted project confirms the permittee's acceptance and agreement to comply with all terms and conditions of this permit.
B. The permittee, in exercising the authority granted by this permit, shall not cause unlawful pollution as defined by Part 31 of the NREPA.
C. This permit shall be kept at the site of the work and available for inspection at all times during the duration of the project or until its date of expiration.
D. All work shall be completed in accordance with the approved plans and specifications submitted with the application and/or plans and specifications attached to this permit.
E. No attempt shall be made by the permittee to forbid the full and free use by the public of public waters at or adjacent to the structure or work approved.
F. It is made a requirement of this permit that the permittee give notice to public utilities in accordance with 2013 PA 174 (Act 174) and comply with each of the requirements of Act 174.
G. This permit does not convey property rights in either real estate or material, nor does it authorize any injury to private property or invasion of public or private rights, nor does it waive the necessity of seeking federal assent, all local permits, or complying with other state statutes.
H. This permit does not prejudice or limit the right of a riparian owner or other person to institute proceedings in any circuit court of this state when necessary to protect his rights.
I. Permittee shall notify EGLE within one (1) week after the completion of the activity authorized by this permit by completing and forwarding the attached preaddressed postcard to the office addressed thereon.
J. All dredged or excavated materials shall be disposed of in an upland site (outside of floodplains, unless exempt under Part 31 of the NREPA, and wetlands).
K. In issuing this permit, EGLE has relied on the information and data that the permittee has provided in connection with the submitted application for permit. If, subsequent to the issuance of a permit, such information and data prove to be false, incomplete, or inaccurate, EGLE may modify, revoke, or suspend the permit, in whole or in part, in accordance with the new information.
L. The permittee shall indemnify and hold harmless the State of Michigan and its departments, agencies, officials, employees, agents, and representatives for any and all claims or causes of action arising from acts or omissions of the permittee, or employees, agents, or representative of the permittee, undertaken in connection with this permit. The permittee's obligation to indemnify the State of Michigan applies only if the state: (1) provides the permittee or its designated representative written notice of the claim or cause of action within 30 days after it is received by the state, and (2) consents to the permittee's participation in the proceeding on the claim or cause of action. It does not apply to contested case proceedings under the Administrative Procedures Act, 1969 PA 306, as amended, challenging the permit. This permit shall not be construed as an indemnity by the State of Michigan for the benefit of the permittee or any other person.
M. Noncompliance with these terms and conditions and/or the initiation of other regulated activities not specifically authorized shall be cause for the modification, suspension, or revocation of this permit, in whole or in part. Further, EGLE may initiate criminal and/or civil proceedings as may be

EGLE
WRP043093 v1.0
Approved
Issued On:12/20/2024
Expires On:12/20/2029

deemed necessary to correct project deficiencies, protect natural resource values, and secure compliance with statutes.

N. If any change or deviation from the permitted activity becomes necessary, the permittee shall request, in writing, a revision of the permitted activity from EGLE. Such revision request shall include complete documentation supporting the modification and revised plans detailing the proposed modification. Proposed modifications must be approved, in writing, by EGLE prior to being implemented.

O. This permit may be transferred to another person upon written approval of EGLE. The permittee must submit a written request to EGLE to transfer the permit to the new owner. The new owner must also submit a written request to EGLE to accept transfer. The new owner must agree, in writing, to accept all conditions of the permit. A single letter signed by both parties that includes all the above information may be provided to EGLE. EGLE will review the request and, if approved, will provide written notification to the new owner.

P. Prior to initiating permitted construction, the permittee is required to provide a copy of the permit to the contractor(s) for review. The property owner, contractor(s), and any agent involved in exercising the permit are held responsible to ensure that the project is constructed in accordance with all drawings and specifications. The contractor is required to provide a copy of the permit to all subcontractors doing work authorized by the permit.

Q. Construction must be undertaken and completed during the dry period of the wetland. If the area does not dry out, construction shall be done on equipment mats to prevent compaction of the soil.

R. Authority granted by this permit does not waive permit requirements under the authority of Part 305, Natural Rivers, of the NREPA. A Natural Rivers Zoning Permit may be required for construction, land alteration, streambank stabilization, or vegetation removal along or near a natural river.

S. The permittee is cautioned that grade changes resulting in increased runoff onto adjacent property is subject to civil damage litigation.

T. Unless specifically stated in this permit, construction pads, haul roads, temporary structures, or other structural appurtenances to be placed in a wetland or on bottomland of the water body are not authorized and shall not be constructed unless authorized by a separate permit or permit revision granted in accordance with the applicable law.

U. For projects with potential impacts to fish spawning or migration, no work shall occur within fish spawning or migration timelines (i.e., windows) unless otherwise approved in writing by the Michigan Department of Natural Resources, Fisheries Division.

V. Work to be done under authority of this permit is further subject to the following special instructions and specifications:

1. Authority granted by this permit does not waive permit or program requirements under Part 91 of the NREPA or the need to acquire applicable permits from the County Enforcing Agent (CEA). To locate the Soil Erosion Program Administrator for your county, visit Michigan.gov/egle/about/organization/water-resources/soil-erosion/sesc-overview and select “Soil Erosion and Sedimentation Control Agencies”.
2. The authority to conduct the activity as authorized by this permit is granted solely under the provisions of the governing act as identified above. This permit does not convey, provide, or otherwise imply approval of any other governing act, ordinance, or regulation, nor does it waive the permittee's obligation to acquire any local, county, state, or federal approval or authorization necessary to conduct the activity.
3. No fill, excess soil, or other material shall be placed in any wetland, floodplain, or surface water area not specifically authorized by this permit, its plans, and specifications.
4. This permit does not authorize or sanction work that has been completed in violation of applicable federal, state, or local statutes.

EGLE
WRP043093 v1.0
Approved
Issued On:12/20/2024
Expires On:12/20/2029

5. The permit placard shall be kept posted at the work site in a prominent location at all times for the duration of the project or until permit expiration.
6. This permit is being issued for the maximum time allowed and no extensions of this permit will be granted. Initiation of the construction work authorized by this permit indicates the permittee's acceptance of this condition. The permit, when signed by EGLE, will be for a five (5) year period beginning on the date of issuance. If the project is not completed by the expiration date, a new permit must be sought.
7. In the event that the permitted activities have begun but are not completed, the permittee or owner of record shall remain responsible for completion of stream restoration as determined by EGLE. Such determinations shall be based on the extent of disturbance to the existing stream.
8. Notification shall be made to the EGLE's Water Resources Division, five (5) days prior to commencement of any activities that affect regulated resources. Please notify Lucas Trumble at 517-420-8923 or TrumbleL@Michigan.gov.
9. "As-Built" construction plans of the project shall be submitted to this office within 30 days of project completion. The "as-built" plans shall be sealed and signed by a licensed professional engineer registered in the State of Michigan and shall certify the project has been completed in accordance with this permit.
10. A storm water discharge permit may be required under the Federal Clean Water Act for construction activities that disturb one (1) or more acres of land and discharge to surface waters. For sites over five (5) acres, the permit coverage may be obtained by a Part 91, Soil Erosion and Sedimentation Control (SESC) permit, or coverage as an Authorized Public Agency (APA), and filing a “Notice of Coverage” form to the EGLE's Water Resource Division. For sites with disturbance from one (1) acre up to five (5) acres, storm water coverage is automatic once the SESC permit is obtained or if work is being conducted by an APA. These one (1) to five (5) acre sites are not required to apply for coverage, but are required to comply with storm water discharge permit requirements. Information on the storm water discharge permit is available from the Water Resource Division's Storm Water Permit Program at Michigan.gov/soilerosion under the “Construction Strom Water Info”.
11. All raw areas in uplands resulting from the permitted construction activity shall be effectively stabilized with sod and/or seed and mulch (or other technology specified by this permit or project plans) in a sufficient quantity and manner to prevent erosion and any potential siltation to surface waters or wetlands. Temporary stabilization measures shall be installed before or upon commencement of the permitted activity, and shall be maintained until permanent measures are in place. Permanent measures shall be in place within five (5) days of achieving final grade.
12. All raw earth within 100 feet of a lake, stream, or wetland that is not brought to final stabilization by the end of the active growing season shall be temporarily stabilized with mulch blankets in accordance with the following dates: September 20 for the Upper Peninsula, October 1 for the Lower Peninsula north of US-10, and October 10 for the Lower Peninsula south of US-10.
13. Historic artifacts could occur on or near this project site and may be impacted by your activities. If during the course of construction artifacts are encountered, immediately contact the State Historic Preservation Office miplace.org/historic-preservation/. Senior Archaeologist Dr. Sara Surface-Evans may be reached at SurfaceEvansS@Michigan.gov; or 517-282-7959; or contact Section 106/Cultural Resource Protection Manager Scott Slagor may be reached at SlagorS2@Michigan.gov; or 517-285-5120.
14. To prevent the spread of invasive species, equipment shall be washed prior to arrival at a new location and when traveling from an area dominated by invasive species to an area not

EGLE
WRP043093 v1.0
Approved
Issued On:12/20/2024
Expires On:12/20/2029

dominated by invasive species within the same route. Soils, organic matter, and all plant material shall be removed from equipment, including the undercarriage.

Dam Removal and Dredging Related Conditions

15. Prior to commencement of any in-stream construction activities, a turbidity monitoring plan should be prepared, submitted to, and approved by EGLE.
16. Prior to commencement of any dredging authorized by this permit, the active dredge areas shall be protected with turbidity curtain and absorbent boom to prevent off-site siltation and to trap any leaks from equipment in the water. The turbidity curtain shall be installed to extend from the bed of the waterbody to a point above the existing water's surface. The turbidity curtain shall be maintained for the duration of the active dredging and grading operations and shall be left in place after disturbed sediments have settled. In the event there is a problem with the turbidity curtain, and a failure to contain the sediments from leaving the project site, the project shall be immediately stopped, evaluated, and appropriate measures shall be taken to stop the release of sediments/turbidity. The permittee, agent or contractor shall immediately notify the Pollution Emergency Alerting System (PEAS) at 1-800-292-4706 and EGLE representative at 517-420-8923 or by email at TrumbleL@Michigan.gov, on the turbidity curtain failure and the measures being taken to stop the release of sediments/turbidity.
17. Prior to the removal of the existing structures, cofferdams, gravel bags, or other flow diversion/barriers shall be installed in accordance with the approved plans attached to this permit. The barriers shall be maintained in good working order throughout the duration of the project. Upon project completion, any accumulated materials shall be removed and disposed appropriately.
18. All cofferdam and temporary steel sheet pile shall then be removed in its entirety, unless specifically shown to be left in place on the approved plans. Cofferdam and sheet pile that is left in place shall be cut off at the elevation shown on the plans and shall be a minimum of one (1) foot below the stream bottom.
19. During removal of the existing dam structure, every precaution shall be taken to prevent debris from entering any watercourse. Any debris reaching the watercourse during the removal shall be immediately retrieved from the water. All material shall be disposed of in an acceptable manner consistent with local, state, and federal regulations.
20. The use of explosives for removal of the structure over the waterbody, including any abutments or piers, is prohibited.
21. Placement of dredge/excavated material into open water, onto ice, or onto exposed bottomland is not authorized by this permit.
22. All dredge material, including organic and inorganic sediment, vegetation, and other material removed from bottomlands, shall not be placed in any wetland, floodplain or critical dune, or below the ordinary high-water mark of any inland lake, Great Lake, or stream. Dredged material placed on upland shall be stabilized in such a manner to prevent erosion of any material into any waterbody, including wetlands, or floodplain.
23. The permittee is advised of other potential requirements and legal liabilities under other statutes for placement of dredge material on upland and is responsible for compliance with all applicable local, state, and federal regulations. Please review the information under Dredging Documents at the attached link: Michigan.gov/en/egle/about/Organization/Materials-Management/solid-waste/exemptions-and-guidance
24. The permittee is cautioned that excessive dredging resulting in the impairment of the structural integrity of seawalls on neighboring riparian properties is subject to civil damage litigation.

EGLE
WRP043093 v1.0
Approved
Issued On:12/20/2024
Expires On:12/20/2029

25. All dredged material shall be disposed of offsite in an appropriate landfill in accordance with the approved plans and specifications.

Fill for Structures Related Conditions

26. All fill/backfill shall consist of clean inert material that will not cause siltation nor contain soluble chemicals, organic matter, pollutants, or contaminants. All fill shall be contained in such a manner so as not to erode into any surface water, floodplain, or wetland. All stone fill shall consist of clean, washed rock or stone that is free of fines, other soil materials, any contaminants, or pollutants. All raw areas associated with the permitted activity shall be stabilized with sod and/or seed and mulch, riprap, or other technically effective methods as necessary to prevent erosion.
27. Stone placed for access causeway, temporary scour protection and structures shall be properly sized and graded based on wave action and velocity, and shall consist of natural field stone or rock (free of paint, soil or other fines, asphalt, soluble chemicals, or organic material). Broken concrete is not allowed.
28. Stone placed for access causeway and temporary scour protection must be removed when in-water work is complete, unless used to achieve final grading for the project.
29. A qualified stream professional familiar with the approved design plans and with expertise in the design and construction of stream restoration projects and natural channel design structures shall be present on-site and shall provide oversight to the construction contractor during construction of all in-stream structures (i.e., j-hooks, constructed riffles, boulder clusters, etc.) to ensure proper placement and elevations of these structures.

Threatened and Endanger Species Conditions

30. The permittee shall follow all the Conservation Measures, Reasonable and Prudent Measures, and Terms and Conditions specified in the United States Fish and Wildlife Services (USFWS), Natural Resources Conservation Service, the City of Grand Rapids Biological Opinion (August 14, 2024) for this project, unless modifications are approved by USFWS.

Floodplain Related Conditions

31. The 100-year floodplain elevation varies according to the Conditional Letter of Map Revision (CLOMR) issued by Federal Emergency Management Agency (FEMA).
32. The hydraulic model submitted for this project shows either the project caused increases in flood stage, or the model showed that the existing FEMA data is incorrect and the corrected data resulted in higher flood stages. Both of these situations require a CLOMR before a Part 31 permit can be issued. The CLOMR has been obtained for this project, allowing permit issuance. Additionally, a Letter of Map Revision (LOMR) is required to officially amend the Flood Insurance Rate Map (FIRM) within six (6) months of project completion. Failure to obtain a LOMR leaves the project in violation of federal National Flood Insurance Program (NFIP) regulations under 44 CFR Part 65.

Tribal/Historic Preservation Conditions

32. The permittee shall follow the Memorandum of Agreement, NRCS Agreement N2622MOU0012399, and any updates to the Agreement, in accordance with 54 U.S.C. § 306114, among the Natural Resources Conservation Service, the Michigan State Historic Preservation Officer, the Michigan Strategic Fund, the City of Grand Rapids, Grand Rapids

Expires On:12/20/2029

Whitewater, Inc. and the Grand Valley Metropolitan Council regarding Removal of Four Beautification (Low-Head) Dams in the Grand River, Grand Rapids, Kent County, Michigan, a component of the Lower Grand River Habitat Restoration and Farmland Conservation Project and any future amendments of said document.

34. The permittee shall follow the Appendix E-Inadvertent Discovery Plan for Cultural Resources or Human Remains for the "*Removal of Four Beautification (Low-Head) Dams in the Grand River, Grand Rapids, Kent County, Michigan, a component of the Lower Grand River Watershed Habitat Restoration and Farmland Conservation Project* as provided in the Memorandum of Agreement which requires immediate work stoppage and notification of the NRCS Cultural Resources Specialist in the event that any items presumed to be greater than 50 years of age such as remains, artifacts, and/or buried features of possible historical or archaeological significance are discovered during construction.
35. The permittee agrees to notify the tribe at least 72 hours before the demolition of Dam #2, located upstream of the Gillett Bridge, from where it meets the riverbank and any part landward begins.
36. If the Gun Lake Tribe or other Tribe wants to visit the site, the permittee shall make a request, on behalf of the Tribe, to the NRCS, who has federal jurisdiction over the project site during the construction period, to allow the Tribe to visit the project site.

Post Construction Monitoring and Maintenance Conditions

33. Permittee shall provide survey monitoring of the completed project for a minimum of five (5) years following completion of construction. An as-built survey shall serve as the baseline for comparison. Follow up topographic/bathymetric surveys shall be completed in years three (3) and five (5) post construction, including at least one (1) survey to be completed immediately following a bankfull or above flood event. Surveys shall also include:
    a. Photographic documentation of the restored stream reach and each in-stream structure (i.e., j-hooks, constructed riffles) and areas of boulder clusters. Photos must be labeled with the location, date photographed, and direction. A map of the locations of the photo stations shall be included.
    b. An assessment of the stability and performance of any in-stream structures. Describe any areas of bank erosion, piping, undermining, end around, significant vertical or lateral migration of fill, or other indication of instability associated with the in-stream structures
34. A monitoring report for surveys completed in years three (3) and five (5), which compiles and summarizes all data collected during the monitoring period, shall be submitted by the permittee. Monitoring reports shall also include survey data from all previous monitoring periods, a discussion of changes or trends based on all monitoring results, and a summary of any problem areas that have been identified and potential corrective measures to address them. Monitoring reports shall be submitted to EGLE prior to January 31 of the year following the surveys.
35. Any in-stream structures (i.e., J-hooks, constructed riffles, etc.) shall perform as designed. The structures shall stay in place and there shall be no bank erosion, piping, undermining, end around, significant vertical or lateral migration of fill, or other indication of instability associated with the in-stream structures.
36. If unacceptable migration of fill or indication of structure instability has occurred, the permittee shall:
    a. Assess the problem and its probable causes;
    b. Assess upstream and downstream impacts of the fill migration;

EGLE

Approved
Issued On:12/20/2024
Expires On:12/20/2029

c. Develop reasonable and necessary corrective measures as a revision to original plans;
d. Within 60 days of identification of the problem, submit to EGLE proposed corrective measures, including a schedule for implementation, for confirmation and approval; and
e. Upon EGLE approval, implement corrective measures according to the approved schedule.
f. Additional monitoring may be required to evaluate the success of the corrective measures.

This permit shall become effective on the date of EGLE representative's signature. Upon signing by the permittee named herein, this permit must be returned to EGLE's, WRD, Dam Safety Unit, for final execution.

Permittee hereby accepts and agrees to comply with the terms and conditions of this permit.
