NATURAL RESOURCES CONSERVATION SERVICE
CONSERVATION PRACTICE STANDARD

BEDDING
(Ac.)

CODE 310

DEFINITION
Plowing, blading, or otherwise elevating the surface of flat land into a series of broad, low ridges separated by shallow, parallel channels with positive drainage.

PURPOSE
To improve the drainage of surface water.

CONDITIONS WHERE PRACTICE APPLIES
This practice applies to all land uses with flat to nearly flat topography and poorly drained soils where a wetland determination and scope and effect evaluation permit the installation of this practice.

CRITERIA
Beds. Bedding shall run in the direction of the available land slope.

Beds shall be shaped and cross-row ditches shall be used, where required to provide free movement of water from the crown to the dead furrow.

Soils must be of sufficient depth to provide a satisfactory root zone after bedding.

Crowns shall provide a cross slope of not less than 0.3 percent.

Capacity. Channel and outlet capacities shall be based on the appropriate surface drainage coefficient, or on recommended removal rates from local drainage guides.

Hydraulic Gradient. Parallel channels shall be graded toward an outlet.

To prevent channel erosion, design velocities shall not exceed those in NRCS National Engineering Handbook, Part 650, Engineering Field Handbook, Chapter 14, Water Management (Drainage), 650.1412(d).

Outlet. Drainage outlets must have sufficient capacity and depth to provide for removal of water from the parallel channels.

CONSIDERATIONS
Flatter fields and tighter soils require narrower beds.

Consider effects on the water budget, especially on volumes and rates of runoff, infiltration, evaporation, transpiration, deep percolation, and ground water recharge.

Parallel channels may be shallow and side slopes steep or flat, based on the soil, crops grown, and local construction and maintenance methods.

Areas where the rooting depth may limit plant growth after construction of the beds should be identified on the plan map.

Consider practices that will mitigate off-site water quality impacts (i.e., wetland treatment areas, filter strips, buffer strips, etc.).

Introduction of non-native species, (e.g. pines introduced to former bottomland hardwood habitat) may introduce species destructive to agricultural crops, or increase the risk of damage from pests or disease.

Soil disturbance increases the potential for establishment of invasive plant species.

PLANS AND SPECIFICATIONS

Conservation practice standards are reviewed periodically and updated if needed. To obtain the current version of this standard, contact your Natural Resources Conservation Service State Office or visit the Field Office Technical Guide.

NRCS, NHCP
July 2010
Plans and specifications for bedding shall identify the area where the practice will be applied; direction of channel drainage; crown height, side slope, and width of bed crosses section; and location of outlets.

**OPERATION AND MAINTENANCE**

The beds shall be maintained to the designed height. Remove sediment from the channels as necessary to facilitate drainage and to prevent ponding. Inspect channels and outlets for damage after storm events. Maintain channels and outlets in a stable condition.
