## *How forecasts are made*

Most of the annual streamflow in the western United States originates as snowfall that has accumulated in the mountains during the winter and early spring. As the snowpack accumulates, hydrologists estimate the runoff that will occur when it melts. Measurements of snow water equivalent at selected manual snow courses and automated SNOTEL sites, along with precipitation and streamflow values are used in computerized statistical and simulation models to prepare runoff forecasts. These forecasts are coordinated between hydrologists in the Natural Resources Conservation Service and the National Weather Service. Unless otherwise specified, all forecasts are for flows that would occur naturally without any upstream influences.

Forecasts of any kind, of course, are not perfect. Streamflow forecast uncertainty arises from three primary sources: (1) uncertain knowledge of future weather conditions, (2) uncertainty in the forecasting procedure, and (3) errors in the data. The forecast, therefore, must be interpreted not as a single value but rather as a range of values with specific probabilities of occurrence. The middle of the range is expressed by the 50% exceedance probability forecast, for which there is a 50% chance that the actual flow will be above, and a 50% chance that the actual flow will be below, this value. To describe the expected range around this 50% value, four other forecasts are provided, two smaller values (90% and 70% exceedance probability) and two larger values (30%, and 10% exceedance probability). For example, there is a 90% chance that the actual flow will be more than the 90% exceedance probability forecast. The others can be interpreted similarly.

The wider the spread among these values, the more uncertain the forecast. As the season progresses, forecasts become more accurate, primarily because a greater portion of the future weather conditions become known; this is reflected by a narrowing of the range around the 50% exceedance probability forecast. Users should take this uncertainty into consideration when making operational decisions by selecting forecasts corresponding to the level of risk they are willing to assume about the amount of water to be expected. If users anticipate receiving a lesser supply of water, or if they wish to increase their chances of having an adequate supply of water for their operations, they may want to base their decisions on the 90% or 70% exceedance probability forecasts, or something in between. On the other hand, if users are concerned about receiving too much water (for example, threat of flooding), they may want to base their decisions on the 30% or 10% exceedance probability forecasts, or something in between. Regardless of the forecast value users choose for operations, they should be prepared to deal with either more or less water. (Users should remember that even if the 90% exceedance probability forecast is used, there is still a 10% chance of receiving less than this amount.) By using the exceedance probability information, users can easily determine the chances of receiving more or less water.

### Helpful Internet Sites

#### Defending Against Drought – NRCS

<http://www.nrcs.usda.gov/feature/highlights/drought.html>

- Ideas on water, land, and crop management for you to consider while creating your drought plan.

#### Arizona Agri-Weekly

<http://www.nass.usda.gov/az/cur-agwk.pdf>

- Provides an overview of Arizona's crop, livestock, range and pasture conditions as reported by local staffs of the USDA's Agricultural Statistic Service and University of Arizona, College of Agriculture.

## SUMMARY

The water supply outlook for Arizona continues to improve. Forecasts call for near median to well above median streamflow levels through the snowmelt season. Most areas have near average or above average snowpack levels for mid March. Reservoir levels are rising and this condition should continue through springtime.

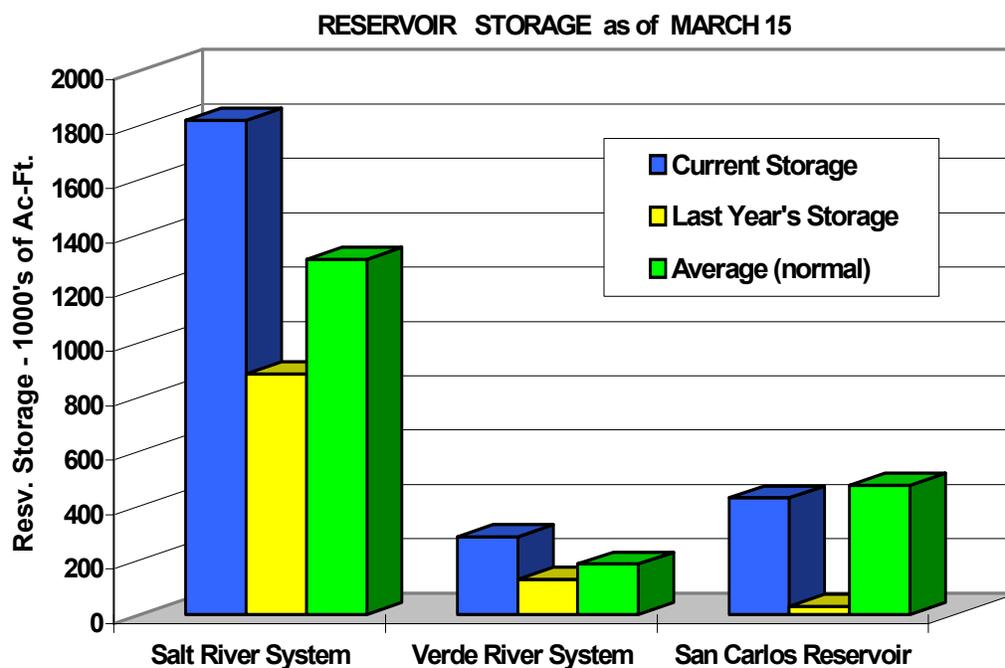

## SNOWPACK

Watershed	Percent (%) of 30-Yr. Average Snowpack Levels as of March 15
Salt River Basin	95%
Verde River Basin	118%
Little Colorado River Basin	103%
San Francisco-Upper Gila River Basin	98%
<b>Other Points of Interest</b>	
Chuska Mountains	119%
Central Mogollon Rim	104%
Grand Canyon	121%
San Francisco Peaks	197%
Statewide Snowpack	123%

## PRECIPITATION

Water year precipitation amounts recorded at high elevation SNOTEL sites indicate well above normal conditions for mid March, ranging from 140% to 203% of average. Additionally, total precipitation amounts for March will be illustrated in the next report, which will be the final issue for the 2005 snow survey season.

## RESERVOIR

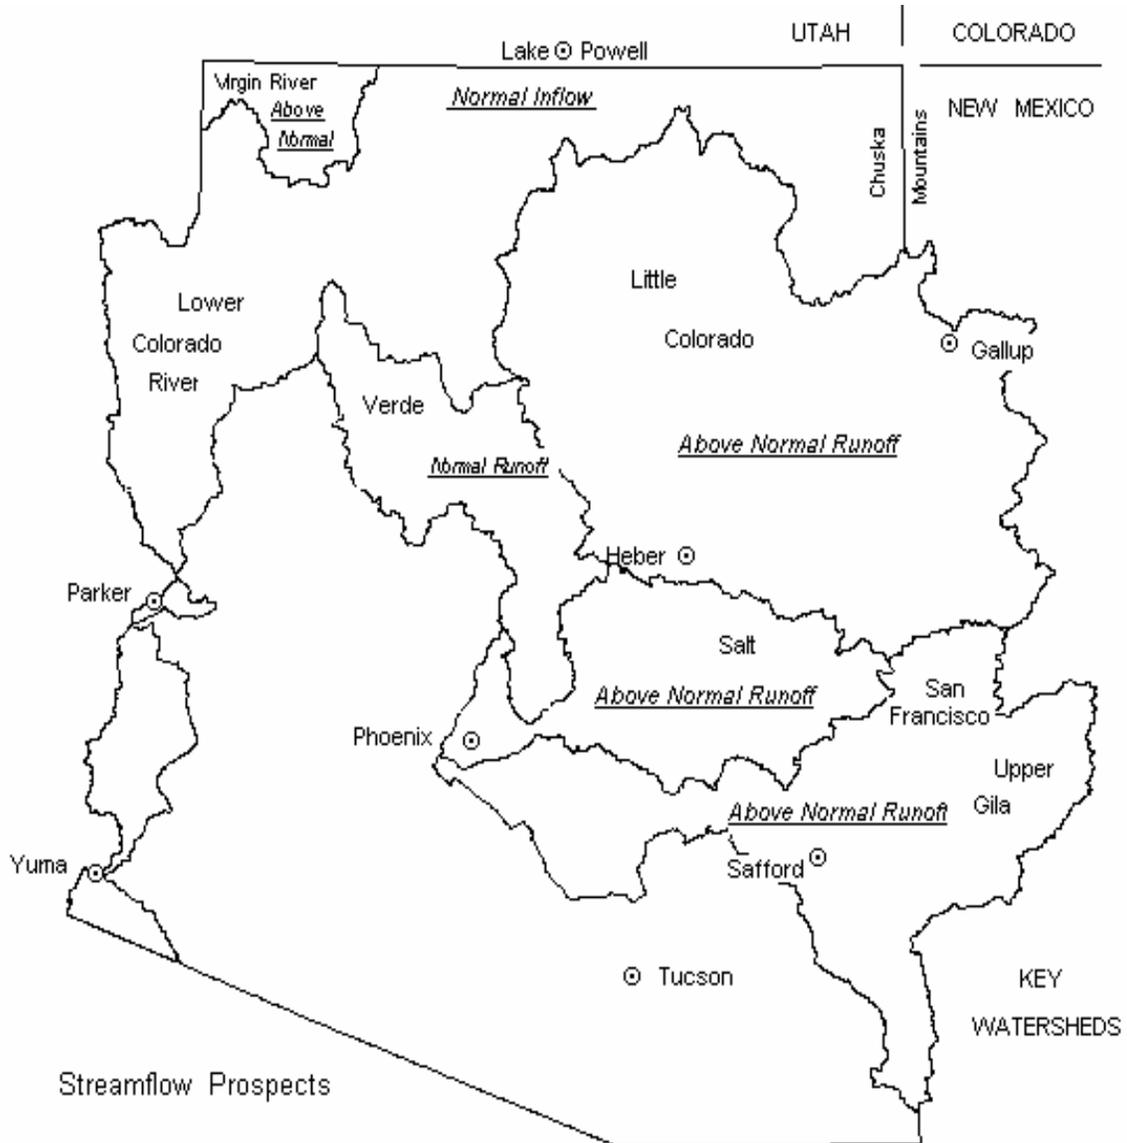

Key storage volumes displayed in thousands of acre-feet (1000 x ):

RESERVOIR	CURRENT STORAGE	LAST YEAR STORAGE	30-YEAR AVERAGE
Lyman Lake	5.4	2.6	16.2
Show Low Lake	6.2	3.5	3.6
Lake Pleasant	801.5	704.4	----
Lake Havasu	546.6	550.7	552.6
Lake Mohave	1728.1	1701.5	1694.0
Lake Mead	16062.0	15371.0	22090.0
Lake Powell	8128.0	10340.0	18366.0
Salt River System	1817.3	883.9	1306.3
Verde River System	284.9	128.5	187.9
San Carlos Reservoir	428.2	29.8	476.9

# STREAMFLOW

Near median to well above median streamflow levels are forecast for all rivers and streams monitored in this report. Additionally, Colorado River inflow forecasts to Lake Powell for the April-July period have decreased from earlier projections to 101% of average.

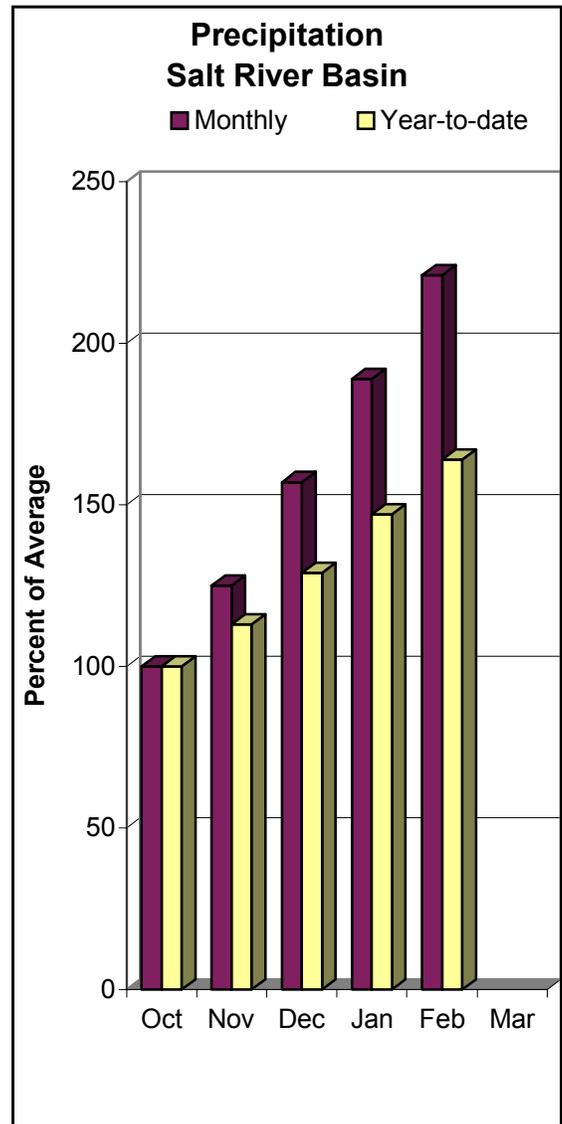

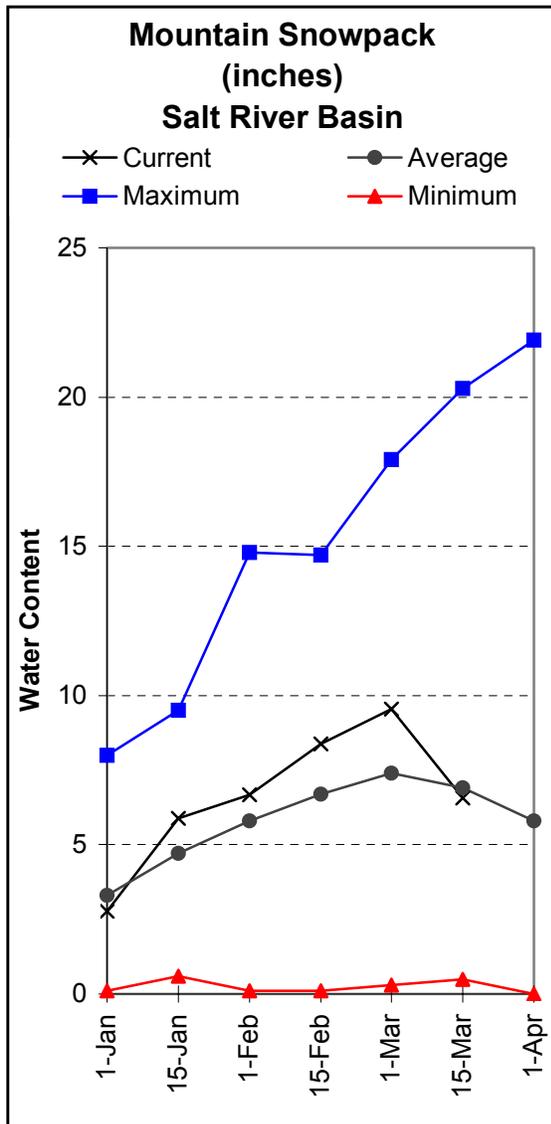

For more information regarding seasonal water supplies, please refer to the streamflow forecast tables found in the report.

## SALT RIVER BASIN as of March 15, 2005

Well above median streamflow levels are forecast for the basin. In the Salt River, near Roosevelt, the forecast calls for 133 % of median streamflow levels through MAY, while at Tonto Creek, the forecast calls for 163 % of median streamflow levels through MAY.

Additionally, snow survey measurements show the basin snowpack to be at 95 % of the 30-year average, while combined reservoir storage in the Salt River system stands at 1,817,326 acre-feet.

SALT RIVER BASIN  
Streamflow Forecasts - March 15, 2005

Forecast Pt Forecast Period	<=== Drier === Future Conditions === Wetter ===>						30 Yr Med (1000AF)
	Chance of Exceeding *						
	90% (1000AF)	70% (1000AF)	50% (1000AF) (% MED.)	30% (1000AF)	10% (1000AF)		
Salt River nr Roosevelt

## VERDE RIVER BASIN as of March 15, 2005

Well above median streamflow levels are forecast for the basin. In the Verde River, at Horseshoe Dam, the forecast calls for 100 % of median streamflow levels through MAY.

Additionally, snow survey measurements show the basin snowpack to be at 118 % of the 30-year average, while combined reservoir storage in the Verde River system stands at 284,878 acre-feet.

VERDE RIVER BASIN

## SAN FRANCISCO-UPPER GILA RIVER BASIN as of March 15, 2005

Well above median streamflow levels are forecast for the basin. In the San Francisco River, at Clifton, the forecast calls for 143 % of median streamflow levels through MAY, while in the Gila River, near Solomon, the forecast calls for 123 % of median streamflow levels through MAY. At San Carlos Reservoir, inflow to the lake is forecast at 135 % of median through MAY.

At San Carlos, reservoir storage stands at 429,186 acre-feet, while snow survey measurements show the basin snowpack to be at 98 % of the 30-year average.

## LITTLE COLORADO RIVER BASIN as of March 15, 2005

Well above median streamflow levels are forecast for the basin. In the Little Colorado River, at Lyman Lake, the forecast calls for 246 % of median streamflow levels through JUNE, while at Woodruff, the forecast calls for 191 % of median streamflow levels through MAY.

Additionally, snowpack levels at the southern headwaters of the Little Colorado River and along the central Mogollon Rim were measured at 103 % and 104 % of the 30-year average, respectively.
