Waterspreading involves the use of a system of dams, dikes, ditches, or other means of diverting or collecting runoff from natural channels, gullies, or streams and spreading it over relatively flat areas.

The purpose of waterspreading is to supplement natural precipitation in areas where extra moisture is needed. Waterspreading systems are suited to locations where the topography and climate are such that additional moisture can be expected to improve plant growth. Areas that receive 8 to 25 inches of precipitation are generally well suited for waterspreading if other site conditions are adequate.

The purpose of the practice is to supplement natural precipitation in areas where extra moisture is needed. Waterspreading systems apply to areas where:

- Soils have suitable permeability rates and water-holding capacity for the crops or forage to be grown on the site.
- The topography and soil are suitable for diversion, collection, and spreading of runoff water.
- Rainfall probabilities indicate runoff or streamflow is available during most years at the appropriate time and volume to significantly increase plant production.

Waterspreading will require maintenance over the expected life of the practice.

Common Associated Practices

Waterspreading (640) is commonly applied with conservation practices such as Dam, Diversion (348), Dike (356), Open Channel (582), Land Smoothing (466), Critical Area Planting (342), Nutrient Management (590), Pest Management (595), and Crop Rotation (328).
