PLANT GUIDE
MANAGEMENT AND USE OF

Basin Wildrye

January 1999

DESCRIPTION
Basin wildrye *Leymus cinereus* (Scribn. & Merr) A. Love (formerly *Elymus cinereus*) is a large coarse robust perennial bunchgrass native to the Great Plains and Intermountain Regions of the Western United States. It is a long-lived cool season native with an extensive deep coarse fibrous root system.

Basin wildrye has long leaf blades (15 to 25 inches); flat wide (up to 3/4 inch) leaves with long pointed auricles. The reproductive stems are dense, stout, and strongly erect. Seedheads are 6 to 10 inches long. Basin wildrye clumps may reach 3 feet in diameter and 3 to 6 feet tall (10 feet under excellent soil and climate conditions). Growing points are 10 to 12 inches above the crown.

Basin wildrye has fair seedling vigor. It is one of the first grasses to initiate spring growth and produces an abundance of basal leaf growth until the development of seed heads in mid-June to mid-July. Following the development of seed heads, basin wildrye produces very little additional basal leaf growth and rapidly becomes coarse and stemmy. Regrowth does not occur following seed production.

IMPROVED CULTIVARS
The Pullman, Washington, Plant Materials Center (PMC), originally collected ‘Magnar’ (*Leymus cinereus*). It was developed by the Aberdeen, Idaho, PMC and released in 1979. It is a selection of vigorous plant types over several generations. It is adapted to the Northwest and Intermountain Regions of the Western United States where precipitation averages 8 inches or above. It has survived in plantings with 6 inches annual rainfall. It prefers deep clayey to loamy to sandy soils and can be found in weakly saline conditions. It is noted for blue foliage, fair seedling vigor and establishment, high forage production, good winter cover, fair winter forage, and ability to survive and thrive under very dry conditions. Magnar is a 56-chromosome cultivar. Certified seed is available, and breeder seed is maintained by the Aberdeen PMC.

‘Trailhead’ (*Leymus cinereus*) was selected by the Bridger, Montana, PMC and released in 1991. The original collection site was near Roundup, Montana, in a sub-irrigated range site. It is adapted to the Northern Great Plains and Intermountain Regions of the Western United States where precipitation averages 8 inches or above. It has survived in plantings with 5 inches annual rainfall. It was selected for its stand longevity and drought tolerance as compared to other basin wildrye accessions. It prefers deep clayey to loamy to sandy soils and tolerates weakly saline conditions. It is noted for green foliage, fair seedling vigor and establishment, high forage production, good winter cover, fair winter forage, and ability to survive and thrive under very dry conditions. Trailhead is a 28-chromosome cultivar. Certified seed is available, and the Bridger PMC maintains breeder seed.

USES
Grazing/rangeland/hayland - Basin wildrye is generally not recommended for spring or summer forage production, because it has an elevated growing point and is easily damaged by overgrazing. It is considered valuable as a late fall through winter cover and forage.

Basin wildrye is palatable to all classes of livestock and wildlife. It is a preferred feed for horses in spring and is considered a desirable feed for cattle, sheep, elk, deer and antelope in the spring. It is considered a desirable feed for cattle and horses in early summer, late fall and winter. It reaches its peak production in protein per acre from mid-June through August. Protein levels can be as high as 20 percent and decrease to about 7 to 8 percent protein as it matures and cures out.

This species is a high forage producer and can be used as winter forage when found in larger stands. It is generally not recommended for haying, because it is difficult to harvest above its natural growing point. Leaving 10 to 12 inches of stubble height will help reduce grazing damage. Once harvested it produces little regrowth.
Basin wildrye is ideal for providing wind protection in winter calving pastures. It holds its nutrient value well at maturity (7-8% protein) and can withstand heavy grazing and trampling in its dormant state. Its tall stature and stiff stems makes this forage accessible in areas of deep snow.

Erosion control/reclamation - Basin wildrye is well adapted to stabilization of disturbed soils. It does not compete well with aggressive introduced grasses during the establishment period, but it is very compatible with slower developing natives such as Snake River wheatgrass, bluebunch wheatgrass, thickspike wheatgrass, streambank wheatgrass, western wheatgrass and needlegrass species. Basin wildryes drought tolerance, combined with fibrous root system and fair seedling vigor, make it desirable for reclamation in areas receiving 8 to 20 inches annual precipitation. It is commonly used as a grass barrier for wind erosion or blowing snow control. It has also been planted on hilly cropland as a vegetative terrace for water erosion control.

Wildlife - Because basin wildrye is a tall upright bunchgrass, it is considered excellent cover habitat for small animals and birds, excellent nesting cover for upland birds, and excellent standing winter feed and cover for big game animals.

ADAPTATION

Basin wildrye is very winter hardy and has a rather broad climatic adaptation. It can be found at elevations from 2000 up to 9000 feet. It grows best in areas with average annual precipitation of 8 inches to above 20 inches. Trailhead has been seeded in areas with as low as 5 inches of rainfall and reproduced to populate areas around original plots. In lower rainfall areas it grows in run-in areas, along gullies or water courses, or near sites with high seasonal water tables. It does not tolerate areas with extended periods of inundation. It will tolerate short-term winter flooding. It is susceptible to leaf and stem rust in wetter climatic areas.

Basin wildrye has a broad soil texture adaptation, but it is not adapted to shallow soils. It is most common on deep soils with high water holding capacities.

It is tolerant of low to moderate levels (< 10 mmhos/cm3) of saline and sodic soil conditions and some low pH soils. Established stands of basin wildrye can tolerate long periods of drought, and it prefers cycles of wet winters and dry summers. It tolerates partial shading and wildfire if soil moisture is not too dry.

It does well as a pioneer plant and establishes seedlings in disturbed areas such as recent road fills and areas disturbed by wildlife such as rodent diggings.

Species often associated with basin wildrye include the big sagebrush complex, juniper species, needlegrass species, bluebunch wheatgrass, Snake River wheatgrass, thickspike wheatgrass, streambank wheatgrass, Indian ricegrass, and Idaho fescue.

ESTABLISHMENT

This specie should be seeded with a disc or deep furrow drill at a depth of 1/4 to 3/4 inch on medium to fine textured soils and 1 inch or less on coarse textured soils. Single species seeding rate recommended for basin wildrye is 8 pounds Pure Live Seed (PLS) per acre or 24 PLS per square foot or 24 pls seeds per linear row foot at 12 inch row spacing. If used as a component of a mix, adjust to percent of mix desired. For rangeland mixtures, approximately 10 to 20 percent of mix or 1 to 2 pounds PLS should be considered.

For mined lands and other harsh critical areas, the seeding rate should be doubled. When seeding is for a vegetative windbreak, vegetative terrace, or wildlife cover, it is recommended that 3.0 to 3.5 pounds PLS be seeded in 36 to 48 inch rows.

The best seeding results are obtained from seeding in very early spring on heavy to medium textured soils and in late fall on medium to light textured soils. Summer and late summer (July to mid September) seedings are not recommended. Seedling vigor is fair, and stands may take 2 to 5 years to fully establish.

Stands may require weed control measures during establishment. Bromoxynil may be applied at the 3-4-leaf stage of grass for early suppression of young broadleaf weeds. Application of 2,4-D should not be made until plants have reached the 4-6-leaf stage. Mow when weeds are beginning to bloom to reduce seed development. Grasshoppers and
other insects may also damage new stands. Use of pesticides may be required. All herbicides and pesticides should be applied according to the label.

**MANAGEMENT**

Basin wildrye establishes slowly and new seedings should not be grazed or hayed until at least late summer or fall of the second growing season. Basin wildrye makes its initial growth in early spring and matures seed by late summer. It reproduces primarily by seed and tillers.

Basin wildrye is palatable to all classes of livestock and wildlife (see USES - Grazing). New stands should not be grazed until plants are at least 10 inches tall. Overgrazing, especially in spring easily damages basin wildrye, and stubble of at least 10 inches should remain following grazing. Basin wildrye is ideal for providing wind protection in winter calving pastures. It holds approximately twice the nutrient value (7-8% protein) of wheatgrasses (3-4% protein) at maturity and can withstand heavy grazing and trampling in its dormant state.

Established stands can be grazed in late spring or fall (leave about 10 inches of stubble to protect plant health). Following grazing, little regrowth can be expected, even when the stand is irrigated. Basin wildrye is a low maintenance plant requiring little additional treatment or care. However, it may benefit from low levels of fertilization. Apply 30 pounds per acre on dryland plantings and 60 to 80 pounds per acre on irrigated plantings for optimum production.

**Environmental Concerns**

Basin wildrye is long-lived and spreads primarily via seed distribution. It is not considered "weedy" or an invasive species but can spread into adjoining vegetative communities under ideal climatic and environmental conditions. Most seedings do not spread from original plantings. If they do spread, the rate is not alarming. Basin wildrye accessions with the same chromosome number (28 or 56) will cross with each other but are not noted for crossing with other native species or basin wildryes of a different chromosome number.

**SEED PRODUCTION**

Seed production of basin wildrye has been very successful under cultivated conditions. Row spacing of 36 inches (3.5 pounds PLS per acre) to 48 inches (3.0 pounds PLS per acre) is recommended. Cultivation will be needed for weed control and to maintain row culture.

Seed fields are productive for five to seven years. Average production of 150 to 200 pounds per acre can be expected under dryland conditions in 14 inch plus rainfall areas. Average production of 300 to 400 pounds per acre can be expected under irrigated conditions. Direct combining best completes harvesting. The seed heads have moderate rates of shatter and require close scrutiny of maturing stands. Seed is generally harvested in mid-August to September. Seed must be dried immediately after combining (12 percent bins/15 percent sacks moisture content).

Foundation and registered seed is available through the appropriate state Crop Improvement Association or commercial sources to grow certified seed.
