Living Landscapes in South Dakota: A GUIDE TO NATIVE PLANTS CAPING

“Helping People Help the Land”
Why is Native Landscaping Important?

Native landscaping provides an attractive, environmentally friendly landscape while reducing water and maintenance requirements. Do you want a beautiful yard, garden, school, park, or parking area? Try a Xeriscape™ with native plants!

The information in this publication will help you select and grow native plants that are naturally adapted and will thrive for years under the extreme environmental conditions of South Dakota. This booklet provides an overview of native landscaping principles and practices. It integrates the principles of reduced water, energy, and chemical usage; wildlife habitat enhancement; and invasive weed management. Native plant, in the context of this booklet, means native to South Dakota, with a few exceptions.

"Fargo Xeriscape Gardens", one of five national Xeriscapes, is a popular urban demonstration of Xeriscape principles and landscapes incorporating native plants. Planting areas display “Moderate Water Use,” “Low Water Use,” and “Very Low Water Use” plants.
Native prairie grasses and wildflowers are excellent alternatives to traditional landscaping. They are less expensive to maintain than turf, require minimal rainfall, and are attractive all year long. Generally, only 50 percent of an existing lawn is actively used. Turf is the highest water-user and requires the most labor in a traditional landscape. Xeriscaping is a water-efficient landscaping technique that reduces water usage and maintenance costs. It uses plants adapted to local climatic and soil conditions, resulting in a lower water usage and maintenance costs.

**Xeriscape and Native Plant Benefits**

### Economic

- Lower water and maintenance costs
- Enhanced real estate values
- Increased survival of plantings
- Edible and/or decorative products

**Black chokeberry: berries used for making wine and jelly**

### Environmental

- Improved water and soil conservation
- Reduced use of petroleum products
- Improved air quality/carbon sequestration
- Enhanced urban wildlife habitat
- Reduced storm water runoff

**Butterfly garden**

### Quality of Life

- Attractive year-round landscape
- Increased wildlife viewing
- Connect with nature
- Decreased mowing

**Big bluestem: fall color**

Native prairie grasses and wildflowers are excellent alternatives to traditional landscaping. They are less expensive to maintain than turf, require minimal rainfall, and are attractive all year long. Generally, only 50 percent of an existing lawn is actively used. Turf is the highest water-user and requires the most labor in a traditional landscape. Reducing the amount of turf will save time and money. Consider using a warm-season alternative turf grass, such as blue grama or buffalo grass. These grasses are slower to green in the spring, quicker to go dormant in the fall, and require less mowing.

Why is Native Landscaping Important?

**What is Xeriscape™?**

Xeriscape (pronounced zeer-i-scape) is derived from the Greek word, xeros, meaning “dry.” Denver Water holds the trademark on the term. It is the wise use of water through water-efficient landscaping and the utilization of plants better adapted to local climatic and soil conditions. The word Xeriscape conjures up visions of a dry, desert-like landscape when, in fact, its focus is how to landscape appropriately in areas with seasonal water supply shortages. A Xeriscape design uses less water to sustain plant life and provides year-round beauty.

Comparisons of traditional landscapes and Xeriscapes have shown that up to 50 percent savings can be achieved in water usage alone. Other study sites indicating potential savings of nearly 30 percent in maintenance and labor, 61 percent in fertilizers, 44 percent in fuel, and 22 percent in herbicides and pesticides.

PLANNING

Steps to Planning

1. **Consider family interests and needs**
   List the outdoor activities and interests of family members, including pets.

2. **Analyze the site**
   Understand the resources: climate, soil characteristics (as determined by a soil test), slope and aspect, topsoil depth, and stability. Identify limitations such as potential flooding or inundation. Identify native plants/plant communities present on the site.

3. **Develop and evaluate alternatives**
   Visualize an initial landscape design that meets your objectives. Consider each of the following when formulating the conceptual plan:
   - **Site**: Is it wetland, riparian, or upland? Can topsoil be salvaged? Should the site be left alone due to potential flooding, bank erosion, or mass soil movement?
   - **Plants**: Are the plants adapted to the site? Consider managing to restore native plant vigor rather than removal and replanting. Identify desirable native plants and ensure they are not damaged by site preparation. Evaluate how the landscape design, site preparation, and planting will affect future maintenance.
   - **Function**: Do the plants meet your objectives for aesthetics, conserving energy, and reducing maintenance time and expense?

4. **Establish budget and timetable**
   Will all the landscaping be put in place at one time or will it progress in phases over several years? How much will be spent and when?

5. **Save or remove existing landscaping**
   All desirable vegetation should complement future plantings. All unwanted vegetation should be entirely removed, either mechanically or chemically.

6. **Solve problems identified in the site analysis**
   Runoff from roof and driveway can be utilized in a rain garden. Are there existing rocks that could be used in the landscape design? Mulches can conserve water and protect soil surfaces from erosion.

7. **Implement plan**
   Order seed, nursery stock, and materials in a timely manner. Plan construction activities to avoid soil compaction and harm to desired vegetation. Use mulch or other suitable measures to prevent erosion during construction and establishment period.

8. **Monitor and maintain landscape**
   Check and protect plants from pest damage and weed competition. Ensure adequate soil moisture.

For more information about soil types in your area, check out the Web Soil Survey at [http://websoilsurvey.nrcs.usda.gov](http://websoilsurvey.nrcs.usda.gov)

Living Landscapes in South Dakota: A GUIDE TO NATIVE PLANTSCAPING

---

CAUTION

Before any digging, trenching, or post-driving, contact South Dakota One-Call. South Dakota Law Chapter 49-7A-5 requires anyone who engages in any type of excavation, with certain exemptions, anywhere in South Dakota, to provide notice of at least 48 hours in advance (excluding weekends and holidays) to South Dakota One-Call. This system is established to notify all South Dakota underground facility operators of intended excavation. Contact South Dakota One-Call at 1-800-781-7474, or 811 for in-state calls, or visit [www.sdonecall.com](http://www.sdonecall.com).

South Dakota One-Call 1-800-781-7474 or 811 (in-state)
Site Inventory and Assessment: Planning and design begin with a thorough site inventory and assessment of the following factors:

**Current and Historic Land Use**
How has the property been used or altered in the past? Are there cultural resources buried or on the surface that should be saved? What level of cleanup will be necessary? These are important considerations before entering the next landscape phase: design, site preparation, plant selection, and planting.

**Vegetative Inventory**
Native species thrive in harmony with their environment. These relationships should be recreated as closely as possible for successful native landscaping. Look around and see what plants exist on the site or a similar site nearby. Do they grow there as part of a natural plant community or were they introduced? Identify the plants and determine if they are annual or perennial.

Identify and control weeds prior to planting activities. Chemical, biological, mechanical, or hand-weeding are all viable options.

**Soil**
Soil is the most important component of landscaping. Many well-designed landscapes have failed because of inadequate soil preparation before planting.

**Compaction** is a significant problem in new developments due to the activity of heavy equipment during construction. Compacted layers severely limit root growth and water movement. This problem should be corrected by ripping or deep tillage before the addition of topsoil or planting.

**Topsoil.** The growth rate and health of landscape plants are directly related to soil quality. Salvage topsoil prior to any excavation to secure a desirable material for plant growth. A minimum of 6 inches of good quality topsoil is recommended for turf; 12 inches for trees. This encourages deeper rooting and provides an organic rich environment for plant growth. Ideal soil textures are fine sandy loam, loam, or silt loam.

**Organic Soil Amendments.** All soil textures may not be ideal for landscaping and garden beds. Two alternatives are available. One, plant site adapted vegetation which may limit species selection, or two, add organic soil amendments that will improve water-holding capacity (sandy soils) or improve aeration and drainage (clayey soils). Organic amendments include peat moss, compost, processed bark, and animal manures. Spread this material evenly over the surface and incorporate to a depth of 2 to 4 inches. The general rule is to incorporate no more than 3 cubic yards of organic material per 1,000 square feet per year. This equals about 1 to 2 inches of organic material.

**Soil Tests.** In landscape settings, soil testing is valuable to establish a baseline on soil pH, salt levels, and the need for nitrogen, phosphorus, and potassium fertilizer. The accuracy of a soil test is influenced by the laboratory analysis but may be influenced even more by the quality of the sample. Refer to SDSU Extension Bulletin titled “Recommended Soil Sampling Methods for South Dakota”. It can be obtained through your local extension offices or at “http://agbiopubs.sdstate.edu/articles/FS935.pdf”.

**Climate**
Climate of the Northern Great Plains is extremely variable and unpredictable. Native plant communities have adapted well to these extremes.

- **USDA Plant Hardiness Zones.** The Plant Hardiness Zone map divides the United States into zones based on average minimum temperature. It should be used to determine plant species adaptation to cold. (See page 6.)
- **Elevation/Topography/Aspect/Hydrologic Regime/Landform and Landscape Position.** These elements influence the length of the growing season, number of frost-free days, wind, sunlight, snow cover, soil depth, and other factors. Landscape position and microclimates around structures can modify growing conditions. Riparian areas, wetlands, and subirrigated sites offer unique opportunities for plant diversity.
- **Precipitation.** Timing of seasonal precipitation dictates water availability which is an important element when establishing and maintaining plants on a site.
- **Wind.** High wind speed exposes plants to moisture desiccation. Warm chinook winds can falsely lure trees and shrubs into breaking bud, making them vulnerable to winter kill. Winter-hardy plants must be selected to avoid damage.
Design

Incorporate wildflower and native grass planting for interest and to reduce the amount of lawn mowing.

Place groupings of trees and shrubs together in naturalistic patterns for visual screens and windbreaks.

Place tree and shrub groupings in common mulch beds to reduce the amount of mowing.

Place plants in areas that would normally be unusable “dead space.” Select plants for amount of sunlight and moisture.

Locate trees away from overhead power lines. Know the ultimate size of the tree.

Locate vegetable gardens with sunlight, access, aesthetic views and moisture in mind.

Locate utility buildings close to gardens and other areas needing equipment. Incorporate out-buildings by blending into the landscape.

Maintain usable lawn areas convenient for use. Reduce the amount of lawn to mow by sizing for the amount that will be used.

Screen objectionable views with carefully selected and placed trees and shrubs.

Locate utility obstructions out of lawn and into common mulch beds.

Collect runoff from downspouts into rain gardens. Utilize plants that tolerate occasional standing water. Locate away from house so water cannot seep into basement.

Place foundation plantings with mulch to help improve consistent moisture conditions surrounding the house foundation.

Extend planting beds around air conditioners and other utilities to remove them from mowable areas.

Extend planting bed edge around trees where possible so trees will have to compete less with lawn.

Create pockets of interesting landscaping using plants with varying shades of seasonal color and contrast.

Design

Information gathered in the site inventory is used to diagram existing conditions and identify functions of various spaces. To better visualize how things appear, drawings and/or design plans are developed to assure that each space gets specific attention and to determine relationships between spaces. The number of steps, or preliminary drawings, necessary to complete a landscape design is dependent on the size and scale of the project and the amount of detail incorporated at each stage of the process.

Landscape Design Sequence

1 Bubble Diagram
   It is important to identify areas with different maintenance requirements. Use simple shapes to represent features or conditions such as a dog kennel, RV parking, turf area, garden, sun exposure, or views.

2 Concept Plan
   Individual shapes begin to take on a greater level of detail, and relationships between spaces evolve. Large areas such as prairies, parking lots, lawns, and water features should be considered first. Smaller areas and shapes, such as planting beds, decks, and walkways should be integrated in and around the larger areas. The diagram at the top of this page is an example of a concept plan.

3 Preliminary Designs
   Plant material is assigned to a space by specific characteristics or function. Important and large-sized plants or groups of plants are located first. Trees, mass plantings, and stand-alone gardens are examples. Actual dimensions of patios, sidewalks and other hard surfaces may be represented.

4 Completed Plan
   The completed plan specifies the identity, location, and proper spacing of all plants. It contains all the information necessary to implement and install the landscape. Construction drawings may be necessary for building or installing other elements in the design.
**Rules of Thumb**

To the casual observer, the prairie grass and wildflower landscape may be perceived as an unkempt lawn. Steps can be taken to promote the introduction of a prairie landscape into the traditional neighborhood.

- Provide one or two strips of mowed lawn between the desired prairie landscape and sidewalks and your neighbor’s lawn. This will lessen the abruptness of the taller grasses that observers may not be accustomed to seeing.
- Talk to your neighbors before installing the prairie landscape. Discuss the beauty, uniqueness, reduced maintenance and water needs, and other benefits of the prairie landscape.
- Provide naturalistic curves to the outside edge of the prairie landscape through the use of mowed strips or visible edging.
- Keep the selection of grasses and wildflowers simple. A short-statured mix of cool- and warm-season prairie grasses and a few selective species of wildflowers will keep the design simple and pleasing to the eye.
- Control weeds. The residential prairie landscape is not maintenance-free, but maintenance may be easier with fewer plant species.
- Consider other design elements such as a naturalistic stone outcropping, ornamental woody plants, a dry creek bed, or sculptures.
- Along borders, place short-statured plants in front and taller plants in the back.
- The width of a perennial border should be proportionally about one-third the height of the background.
- In island planting beds, place taller plants near the middle and decrease height toward the edge. The most pleasing effect is achieved if the bed is twice as wide as the tallest plant.
- Place plants according to their needs for sun, water, and soil condition.
- Arrange plants so they are visible and colorful throughout the year.
- Space plants based on mature size.
- Consider surroundings in design. Use plant screens or barriers as necessary for privacy.
- Recognize maintenance issues.
- Try different plant material as long as it is recommended for the site.
- Don’t be afraid to experiment.

**Eye Grabbers**

**Do**

- Group 3, 5, or 7 plants together
  - unifying
- Match plant size to available space
  - proper scale
- Accent with fall color and leaf color
  - cheery
- Vary size, spacing, and diversity
  - interesting

**Don’t**

- Scatter single plants here and there
  - spotty and confusing
- Incorporate many big trees on a small lot
  - overpowering
- Plant large plants too close to house
  - structural damage
- Plant if unable to maintain
  - time-consuming

**USDA Plant Hardiness Zones**

**Average Annual Minimum Temperature**

The complete USDA Plant Hardiness Zone Map is numbered 1 through 11, with zones 2 through 10 subdivided into “a” and “b” regions. Each zone is 5 degrees warmer (or colder) in an average winter than the adjacent zone.

The map is based on average annual minimum temperatures recorded throughout North America. By using the map to find the zone in which you live, it will enable you to determine what plants will “winter over” in a yard or garden because they can withstand these average minimum temperatures.

Although these zones are useful as an indicator of a plant’s likelihood for survival in a given area, many factors, including soil type, soil moisture and drainage, humidity, and exposure to sun and wind will determine a plant’s growth and success or failure in its environment.
SITE PREPARATION

Site preparation methods, sequence, and timing are important considerations to achieving landscaping goals. Site preparation includes (1) retaining desirable trees and vegetation, (2) maintaining or improving soil quality, (3) removing unwanted vegetation, (4) preparing seedbed, (5) transplanting, and (6) seeding grass and forbs.

Retaining Desirable Trees and Vegetation

Careful planning can prevent inadvertent loss of desirable vegetation. Stockpiled soil can suffocate vegetation within a few days. Stockpiled building materials may trap solar heat and destroy vegetation in a few hours. Herbicide drift, leaching, or translocation in soil can destroy existing trees and vegetation. Residual herbicides in the soil could negatively impact, or kill trees and vegetation for days or years after application.

Additional practices that are detrimental to tree health and development include:

- Trenching through tree roots
- Removing soil from over the root system of the tree
- Adding soil over the root system (As little as 1 inch of clay spread on top of the roots of a mature tree can cause it to decline.)
- Physical injury to tree trunks or limbs
- Traffic on root systems causing compaction
- Tilling deeper than 1 to 2 inches over the root area

Grasses and forbs can also be damaged through:

- Disturbance of topsoil
- Compaction

Stockpiled soil or construction materials can kill sod – a very real loss if the sod grew native plants.

Tree roots cut during excavation cause a tree to decline and die.
Maintaining or Improving Soil Quality

Maintaining soil quality is important for sustaining healthy plants, reducing erosion, and improving nutrient and water use efficiencies. If topsoil is removed during construction, it should not be mixed with subsoil, and should be carefully stockpiled for resurfacing landscape planting areas. A minimum of 6 inches of topsoil is preferable for growing most plants. There may be a need for additional organic matter for some soils. Utilize soil sampling/soil test kits and the professional services of your local plant nursery, garden center, or SDSU Extension Service to assist with soil quality needs.

Construction and landscaping activity and other factors may result in soil compaction, and therefore, inhibit root growth and water absorption. To test for soil compaction, dig into the soil. A shovel should penetrate easily in undisturbed soil that has good structure and porosity. The soil should crumble and flake apart easily. Soil compaction may be alleviated by:

- Incorporating organic matter into the top 6 inches of the soil (well-rotted manure, straw, compost, grass clippings, leaves, peat moss, processed bark, etc.)
- Reducing traffic impact on the soil by limiting the number of trips and using lighter equipment
- Waiting for wet soils to dry before tillage

Preparing Seedbed

Before seeding disturbed sites, allow settling to occur. Watering may help settle the site, but too much or too fast will increase compaction or cause erosion.

Grass seeding requires a firm seedbed. Firming can be accomplished by an implement such as a harrow, roller-packer, ATV or vehicle tires, or foot traffic. When walking across a firm seedbed, an adult footprint should not sink over ¼ to ½ inch.

Removing Unwanted Vegetation

Herbaceous vegetation can be effectively controlled with herbicides or repeated tillage. Note that repeated tillage may trigger water and wind erosion on many sites. Bare sites should be replanted or covered with mulch as soon as possible to control erosion and reduce weed infestations. When using herbicide control, select herbicides that:

- Are labeled for use in South Dakota.
- Effectively destroy the target vegetation, including the tougher invasive plants
- Have no carryover soil residual activity

Consult the SDSU Extension Service for site-specific herbicide application information.

Transplanting

A wide variety of native shrubs, trees, and forbs are available through commercial sources. For a variety of reasons, avoid harvesting plant materials found in the “wild.”

Transplanted roots should be kept moist at all times but not stored in water. The planting site should be moist but not wet. Place plants at the depth grown in the nursery. Fine lateral roots should be in the top 1 to 2 inches. Water as needed the first year to keep root zone moist to touch.

Seeding Grasses and Forbs

Plant grass seed ¼ to ½ inch deep. Seeding can be accomplished by broadcasting or using a grass drill. Grass drills effectively control seeding depth and provide even seed distribution. However, they may leave visible drill rows.

Broadcast seeding is an effective seeding method, and will not leave visible drill rows. When broadcasting seed, spread half of the seed in one direction and the rest in another, to avoid gaps. When seeding is completed, rake, drag, or harrow to cover the seed with soil. To promote even germination, cover the seeded site with sterile mulch (clean straw, mulch, grass clippings, etc.). The soil surface should be kept moist (not wet) until seeds germinate. Water as needed to keep root zone moist.

Roller packing before seeding grass is a key to success.
Choosing the Right Grasses and Wildflowers

Plant Attributes and Features

When selecting plant species, consider contrast, harmony, and boldness to provide variety throughout the year. Allow ample room for growth as the plant matures.

Know the life-span of your plants.
- **Perennial** - lives three or more years, resuming growth each growing season from overwintering buds above or below ground.
- **Biennial** - requires two growing seasons to complete their life cycles; germinating and remaining vegetative the first year, then flowering, fruiting, and dying in the second year.
- **Annual** - completes its life cycle within one growing season and must reproduce from seed each year.

Nature’s Defenses

In nature’s low-water environments, look for attributes considered natural defense mechanisms for conserving water.
- Hairy, sticky, or wavy leaf surfaces deflect wind and channel water droplets.
- Short, narrow, incised leaves have smaller surface area and lose less water to evaporation.
- White or silvery-colored leaves reflect the sun’s rays and modify leaf temperatures.
- Spines, prickles, and aromatic foliage defend against loss of stem tissue and moisture from hungry, thirsty predators.
- Small, less showy flowers with little or no fragrance attract less attention from predaceous insects and grazing animals.

Plant Adaptation

Plants naturally adapted to survive in local environmental conditions should be selected.

- Choose reputable nurseries and garden centers. Many choose and grow native and introduced plant material that is adapted to the area. Consider their replacement policy. Guarantees usually vary from 6 months to 1 year from purchase.
- Select plants adapted to the correct USDA Plant Hardiness Zone. The “zone” will be listed on the tag or label. The lower the number, the more adapted it is to colder temperatures. In South Dakota, depending on your location, the zones range from 3b to 5a. Species, as well as varieties within the species, need to be adapted. Varieties or cultivars originating from milder southern climates often have different day length and length of growing season requirements, and lack of winter hardiness.
- Research a plant’s adaptation using the two-word scientific Latin name for the species. It is more universal than a common name. Common names vary in time, place, and culture.
- Though plants from the wild are adapted, digging for home landscaping use is not recommended. Extensive root systems often make digging and transplanting unsuccessful. It is also illegal in many areas. When gathering seed, consider viability and propagation requirements. Seed quality is often poor in the wild. Many species require special conditions and treatments for germination. Knowing these needs is essential for successful establishment from seed.

Tag Tips:
- Scientific Latin name of one or two words, for example, Linum lewisii.
- “Zone” numbers, i.e., 3 means better adaptation to colder temperatures than 4.
- Sun, partial sun, or shade tell you the sunlight requirements and correct placement in the landscape.
- Water requirements in inches per year should fit natural, local precipitation amounts.

Purple coneflower, a native wildflower, is grown and sold at many nurseries.

Mature purple coneflower
Grasses can be used in a landscape as an accent plant or a ground cover. Grasses can be compact and tufted, erect in bunches, creeping on the ground’s surface, or spreading as sod. Height varies from ground-hugging to several feet tall. Depending on their time of growth, they are considered either warm- or cool-season species.

- **Cool-season** species green up early and actively grow during the cool, moist periods of the year such as from spring until mid-summer.
- **Warm-season** species begin growth in early summer and remain active until mid-autumn. In the fall, they often have attractive, colorful foliage.

Wildflowers vary greatly in size, shape, color, bloom season, and duration of bloom. Knowledge of these characteristics will help to choose and coordinate plantings that provide interesting color throughout the entire growing season. Some wildflowers require direct sunlight for 6 to 8 hours per day. As sunlight decreases, plant height and bloom size decrease.

**Native Plant Attractions**

- **Fragrance**
- **Herbal and medicinal qualities**
- **Color schemes**
- **Bloom schedule**
- **Shape and texture**
- **Natural habitats recreated**
- **Winter landscape appeal**
GRASSES

Grasses can bring texture and softness into a landscape design. A wide diversity of native grasses provides endless opportunities for adding color, an assortment of sizes and shapes, and offers relatively low maintenance. Favorable characteristics of most native grasses include low water and fertility requirements. They reach their ultimate size quickly, have a high resistance to insects and diseases, and generally can fend for themselves.

Native grasses in landscaping can include a broad range of uses, i.e., ground cover, monoculture manicured lawns, individual accent or specimen plants, and prairie or meadow restoration.

Ground Cover
Grasses that spread by rhizomes, stolons (above-ground runners), or tillers are prime candidates for ground cover and site stabilization. Steep slope stabilization, however, may require structural stabilization prior to plant establishment. Initial weed control is critical until the cover plants are established well enough to shade out or crowd out any unwanted plants.

Blue grama has “eyebrow” seed heads.

Winter color of little bluestem in new snow.

Buffalograss stolons cascade down a rock face.

Lawns
The use of native grasses for a manicured lawn involves the same site preparation and establishment techniques as with a Kentucky bluegrass lawn. The seeding rates are increased [500 Pure Live Seeds (PLS) per square foot] to ensure a dense, solid stand. Depending on the amount of water applied to a site (natural or supplemental), the plant density will eventually adjust to that which the site can maintain. Mulching and early supplemental water will help ensure a good initial stand. Rhizomatous species will continue to fill in the open spaces, but bunchgrass stands may develop gaps if the initial establishment is sparse. Although the emphasis of this publication is on native species, there are some introduced grasses that, because of their drought tolerance and low maintenance, can be used for manicured lawns.

Prairie/Meadow
In some suburban areas and particularly in rural settings, a person may want to restore large areas to native prairie or meadows, blending a residence into a natural setting. To restore a natural plant community, there are several establishment options: 1) seed general mixtures of grasses and wildflowers, using most of the species you want in your end product; 2) seed simple mixtures and interplant to increase diversity; or 3) transplant all plants to spacing and composition desired. Once established, native prairies or meadows require minimal maintenance, spot weed control, and early spring residue management.

Buffalograss and Blue grama Establishment
Prior to warm season grass establishment a weed free seedbed should be prepared. Multiple applications of a non-selective herbicide such as glyphosate should be considered to remove cool season perennials such as quackgrass, smooth brome and Kentucky bluegrass before seedbed preparation begins. Buffalograss and blue grama should be planted to a depth not exceeding ¼ inch in mid-May through mid-June. Use only improved cultivars for South Dakota such as: Bad River or Willis blue grama and Bowie, Cody, Sharpshooter, or Legacy buffalograss. A mixture such as Bad River blue grama and Bowie buffalograss is a combination that will provide for color uniformity. If seeded in combination, the seeding mix of 80% blue grama and 20% buffalograss is recommended.

Once fully established, buffalograss is highly competitive with weeds. However, during the first few years of establishment, use proper mowing in combination with fall glyphosate treatments when the grass is fully dormant for the control of cool season species. The control of summer annual weed competition can be accomplished through the use of pre-emergence herbicide treatments such as pendimethalin (Journey, Pendulum) or dithiopyr (Dimension), and post-emergence treatments such as imazapic (Plateau), quinclorac (Drive), or Metsulfuron (Metgard, Riverdale Patriot, Escort). If fertilizer is applied to an established buffalograss lawn, annually apply 1 lb. actual nitrogen in mid-June and again in mid-July.

1 Seeding rates for lawn are figured at approximately 500 PLS per square foot; 2 Seeding rates for a prairie grass stand are figured at approximately 40 PLS per square foot; 3 Rating scale: Excellent - Good - Moderate - Fair - Poor
**Grasses**

**Buying Seed**

Much of the grass utilized in native landscaping will be established from seed. The buyer must be aware of what he/she is buying, both in terms of quality and what undesirable material may be in the seed lot. All seed sold in South Dakota is required to meet certain standards; i.e., the seed lot can’t have more than 2 percent weed seed and must be totally free of certain noxious weeds. By buying certified seed you are guaranteed that it is indeed the species and variety/cultivar as labeled, meets minimum purity and germination standards, and specific limits on the amount of weeds and other crops allowed. Purchase seed on PLS basis.

**What Should A Seed Tag Tell You?**

Seed tags vary in layout and design from state to state, but all have generally the same information.

**Accent/Specimen Grasses**

Accent or specimen grasses are individual plants or clusters that are space-planted, usually with weed barrier and bark, gravel, or decorative rock mulching. These types of plants are best established using containerized plant material transplanted in desired spacing and patterns. Many of the warm-season and tall stature grasses are used because of their fall colors and attractive seedheads, with secondary advantages of wildlife food and cover. Specimen plants may require some fall/winter or early spring maintenance to remove dead plant material and unwanted plant litter. The bunchgrass varieties of grasses are ideal for specimen plantings because they do not spread, retaining their individuality in a space-planted design.
Wildflowers

Perennial wildflowers live for more than two years. They offer something for everyone and are relatively easy to maintain.

- **Seeding:** Wildflower seeds are often very small, fluffy, or irregular-shaped, making it difficult to control the total amount dispersed. For example, aster and yarrow are better interplanted as small plugs of rooted plants. That way, there is less chance of overseeding and crowding out other species in the garden.

- **Potted Plants:** Containerized material should be healthy—leaf and stem colors appear normal with little or no yellowing or discoloration. Smaller containers are less expensive but greater numbers are required to fill an area. Larger material will be readily noticeable, but cost more to install.

- **Planting:** Prepare the soil well ahead of planting. Avoid planting during the hot, dry months of summer. For potted plants, follow spacing recommendations and keep watered prior to and after transplanting. Sow seed into a firm, moist seedbed, mulch lightly, and apply frequent, light sprinkler irrigation. Monitor and inspect for insect pests and control weeds as they appear.

- **Maintenance:** Extend the flowering period and promote re-bloom by “deadheading” the flower after it dies. Use sharp pruning shears to cut and remove the dead blossom. When plants reach maturity, divide the crown into smaller portions and transplant into another area, recycle to a like-minded gardener, or add to the compost pile. In late fall or early spring, cut back all dead plant parts. Remove debris to reduce pest and disease problems.

**Landscape Uses**

Wildflower use in the landscape is unlimited, as plants are available in many sizes, shapes, and colors. Plants that have similar water and light requirements should be grouped together. The development of a landscape plan is recommended and landscape design professionals can be consulted for assistance.

**Specimens**

Specimens are separate, individual plants that attract attention to their ornamental beauty. They are generally selected for large size and stature, or for unusual shape, color, or texture. Specimens function as solitary elements for viewing from all sides or as a dominant feature in a mass planting. They should be used sparingly to avoid attracting attention to many different points.

**Borders**

Border plants are used along the edge of a structure, hard surface, or lawn area. They function as hedges, screens, traffic guides, and foundation plantings. Open and semi-open space can be defined with the use of borders. Limit number of plant types to avoid visual chaos.

**Mass Plantings**

Massing similar plants in a group mimics nature and creates a sense of unity in the design. Natural environments have clusters of vegetation that slowly shift in composition with altering conditions. Mass plantings act as an orderly connection among other planting groups.

**Ground Covers**

Heath aster, when mowed short, provides late season color and ground cover. Spreading and low-growing plants cover areas that are impractical to maintain as a lawn. They are used on slopes, along pathways, under shade or tree canopies, and between plants in flower beds. Consider converting lawn space to a ground cover for reduced water consumption.

**Poisonous Plants**

It’s wise to inquire about a plant’s potential toxicity before placing it in a landscape. The foliage of some plants is known to be poisonous to people, pets, and domestic livestock. A few of the more common ones include bleeding heart, buttercup, clematis, foxglove, goldenrod, horsechestnut, larkspur, locoweed, lupine, milkweed, monkshood, oak, poppy, and water hemlock. Visit your local bookstore or library, or the website provided in the reference section.

Choosing the Right Trees and Shrubs
Selecting the Best Type of Nursery Stock

Types of Nursery Stock

Bareroot
These plants are dug and shipped as dormant 1- to 4-year-old stock without any soil surrounding their roots. For most situations, bareroot stock should not show leaf emergence at the time of purchase. Late planting season purchases may show slight leaf emergence but will require more stringent planting and maintenance the first year to ensure survival. Conservation grade conifers are also produced as bareroot stock.

Bareroot
- inexpensive
- proper storage and transport is critical

Container
These plants are grown in a pot for at least one growing season. Stock grown in a pot, especially stock carried over from one season to the next, may develop girdling roots that need to be gently loosened from the root ball and spread radially from the trunk at planting. If this is not possible, make one or two vertical slashes 1 to 2 inches deep through the root ball to sever girdling roots.

Potted
Bareroot stock is planted in pots just weeks prior to spring sales. Generally, by the time of purchase, little root growth will have occurred. Though not grown in the pot, these plants can be used successfully if proper depth and root orientation are achieved. Potted stock extends the planting season compared to bareroot stock.

Potted
- cheaper than balled and burlapped
- heavier to handle than bareroot

Balled and Burlapped (B&B)
These are hand or mechanically dug field-grown plants that have their roots and surrounding soil wrapped in burlap fabric and secured with twine or pins. Used primarily for large, field-grown stock. Once the plant has been placed at the proper depth in the planting hole, all twine and burlap should be removed. It is permissible to leave small inaccessible amounts directly beneath the bottom of the ball.

B&B
- reduced transplant shock on smaller stock (better survival)
- “instant” tree

Wire Baskets
This is a form of B&B that utilizes a wire basket to secure the root ball in lieu of twine. All wire and burlap should be removed after the plant has been placed in the planting hole. It is permissible to leave small inaccessible amounts directly beneath the bottom of the ball.

Wire Baskets
- “instant” tree

ADVANTAGES

Bareroot
- inexpensive
- ease of planting
- field grown hardiness
- easy to replant
- adapts to planting site soils

Container
- long planting season window
- reduced transplant shock
- trees may be leafed at purchase
- adaptation to onsite soils may be delayed

Potted
- cheaper than balled and burlapped
- can be planted after bud break
- easier to determine healthy stock

B&B
- reduced transplant shock on smaller stock (better survival)
- “instant” tree

DISADVANTAGES

Bareroot
- proper storage and transport is critical
- roots easily desiccated (1 to 2 minutes air exposure)
- shorter planting time frame

Container
- more expensive than bareroot
- may have more girdling roots
- heavier to handle than bareroot

Potted
- heavier to handle than bareroot
- have to treat as bareroot to ensure proper root alignment
- soil often falls off root ball

B&B
- expensive
- heavy
- difficult and expensive to replant
- proper depth placement more difficult
- generally fewer species available
- excessively large stock may not grow for years

TIP:
Avoid purchasing plants with abnormally small leaves, leaves that are unusually yellow or with brown scorched margins.
Tree and Shrub Health

The outward appearance of a plant can provide insight into its overall health. Examine nursery stock closely before purchasing it.

Healthy Roots
- Actively growing stock should have white root tips.
- Healthy plants should have enough fibrous root mass to retain the shape of the root ball once the container or burlap is removed.
- Bareroot material should have a shoot to root ratio of 1:1 or 2:1 with extensive, fibrous roots.

Healthy Trunk and Branches
- A healthy tree trunk should be straight, slightly tapered, and capable of remaining upright on its own. It should be uniformly branched along its length with half the leaf area in the lower two-thirds of the canopy.
- The trunks of large trees should be firmly connected to the root ball (i.e., not move independently).
- Branches should be free from signs of mechanical injury, sunburn, sunscald, insect, disease, or other forms of stress.
- The branches and tops of trees should not be severely pruned.
- Stems should have no insect borer holes, and any injuries should be less than ½ inch in size.

Healthy Foliage
- Adequate and uniform foliage
- Leaves appropriately sized and uniformly colored for the species
- No signs of bud swell or growth should appear on dormant stock.

Geographic Suitability
Generally, plants perform better if they are planted within 200 miles North-South and 400 miles East-West of where they originated. Origin means where they grew and developed naturally, not the location of the wholesale nursery.

TIP:
Determine proper planting depth for potted, B&B, and wire basketed trees by gently probing with a finger or trowel through the top of the soil immediately adjacent to the stem. Avoid damage to bark or roots. Measure from the trunk flare to the bottom of the pot or root ball. Dig the hole no deeper than that. Trunk flare is that part of the trunk with a noticeable diameter increase at the juncture with the roots.

TIP:
On healthy trunk or limb tissue, a shallow scratch with a fingernail reveals a light green cambium layer between the bark and the wood. No green means tree is dead.

Choosing the Right Trees and Shrubs
Intermediate Care, Storage, and Handling of Trees and Shrubs

Transport all stock in a covered vehicle to prevent dessication of the tops and drying of the roots. Bareroot stock should have the roots covered with saturated (soaked in water for several hours) shingle tow, wood shavings, sphagnum moss, or shredded paper. The root coverings should be moist for the entire trip, but the roots should not be immersed in containers of water.

Bareroot plants are shipped dormant and should be planted as soon as possible, usually within 72 hours of leaving the nursery. For short storage intervals (less than 3 days), bareroot plants can be kept in cool, shaded locations outdoors or in a cool basement. Cover the roots as was done for transport from the nursery. Inspect daily to ensure root covering remains moist. Make sure all the root covering is thoroughly saturated. It works best to soak the root coverings in a bucket of water before covering the roots. The root covering material should always be wet enough that a bit of water can be squeezed from a handful. Keep seedlings out of direct sun, and protect from wind dessication and heat build-up. Never let the roots dry out during the planting process, even for a few seconds. For time periods of less than an hour, bareroot trees can be transported in buckets of water during the planting process. Do not damage roots during storage or planting by bending, breaking, scraping bark, etc.

Container/potted plants offer more flexibility in planting, handling, and storage than bareroot stock. The soil in the pot provides a limited amount of water storage permitting active growth when weather conditions permit. Check daily and water as needed to wet the entire pot. Ensure that pots have drainage holes to allow excess water to drain. Container plants may have been potted just before purchase or they may have been grown in the pot for several seasons. Store container stock in a wind-protected area out of direct light. When planting, container stock should be removed from the pot.

Balled and Burlapped (B&B) material often requires special handling given the size and weight of the plant, roots, and soil. Do not move B&B plants by the trunk alone. Support the trunk and root ball simultaneously to assure the roots are not broken at the trunk surface. Never drop a B&B plant abruptly on the ground, even from a slight elevation. Gently slide or roll large B&B plants into the planting hole. Never attempt to move an excessively wet root ball. Store B&B material as you would container plants. Media such as a sand/peat mix may be used to cover the root ball during long-term storage. Special provisions may be needed to secure the plants during storage in high wind locations.

**Growth Rate:** Slow=<1’ per year; Medium = 1-2’ per year; Fast = >2’ per year. **Shade Tolerance:** N = Not Tolerant; I = Intermediate; T = Tolerant. **Wildlife Food:** W = Winter food and growing season food; S = Growing season food; N = Not a food source. **Wildlife Cover:** N = nesting; L = loafing; E = escape; W = winter; B = Beneficial to butterflies. **Fall Leaf Color:** Note that colors may vary between seasons and due to soil chemistry for the same species. **Minimum Precipitation:** H = needs water in addition to precipitation. * = Introduced Species – Though introduced, Colorado Blue Spruce and crabapple can be used to provide many aesthetic and wildlife benefits. Except for very rare site conditions, these species will not establish offsite from roots or seeds.
Living Landscapes in South Dakota: A GUIDE TO NATIVE PLANTSCAPING

TREES AND SHRUBS
Anatomy of a Properly Planted Tree

1-800-781-7474 or 811 (in-state)

Always call SD One-Call before digging.

TIPS: TREE PLANTING

* Do not leave roots exposed to the air for even brief periods. Keep bare-root plants covered with wet burlap, sheets, or blankets during the planting process. Make sure roots are fully extended and spread radially from the trunk in planting hole.

* Always remove the plant from the pot prior to planting.

* All burlap, ties, synthetic wraps, and wire baskets should be removed once the tree is positioned in the hole. A small inaccessible amount, directly beneath the root ball, may be left.

Steps to Tree Planting

Step 1: Dig hole 2 to 3 times wider than the diameter of the root ball or pot. It should be no deeper than the root ball. The trunk flare should be partially visible above the firmed and watered soil.

Step 2: If present, break through impervious soil layers to allow root expansion. If deeper than the planting depth, be sure to backfill and firm material to prevent settling of the tree.

Step 3: Bareroot – spread roots radially from trunk. Potted – remove pot, untangle roots, and spread radially from trunk. Container grown – remove pot, inspect for girdling roots. If present, make several vertical cuts with sharp knife about 2 inches into root ball. Ensure that a portion of the trunk flare will be above existing soil grade. Remove all twine, netting, and wire baskets. It is permissible to leave small inaccessible amount directly beneath the bottom of the ball.

Step 4: Make sure trunk is vertical.

Step 5: Backfill to half of depth; lightly pack. Water to top of hole. Replace remaining soil once water has soaked away.

Step 6: Construct a small berm 2 to 3 inches high around perimeter of planting zone to retain water in root ball zone.

Step 7: Use protective devices (tree wrap, fences, tree shelters, aluminum foil, etc.) to protect trunks from mechanical damage, and animal and weather injury. Inspect trunks annually for potential problems.

Step 8: For tall stock, install 2 to 4 stakes to prevent wind damage. Stakes should be long enough to bury 12 to 18 inches in the soil and support trees at the mid-point of the trunk or just below the canopy. Wood stakes should be 2x2s to resist breakage. Remove after 2 years.

Step 9: Use soft, nonabrasive material that will permit tree 6 to 12 inches of side-to-side movement in wind. Remove after 2 years.

Step 10: Spread 3 to 4 inches of high quality coarse, organic mulch. Avoid deep mulching against trunk. Add thin layers of mulch every few years to maintain effective weed control, improve water infiltration, and protect roots from temperature extremes. Areas mulched around trees also protect from lawn mowers and line trimmers.
In the development and maintenance of a native landscape, water conservation is the driving force behind efficient and aesthetic designs. Plants should be grouped in separate water-use zones according to their water needs and function within a landscape. Monitoring soil moisture to determine when to irrigate is better than using a pre-set schedule. The soil water-holding capacity will vary with soil type, amount of organic matter, and climatic conditions.

Supplemental Water Requirements

**Seedings:** A moist soil profile, at time of planting, will increase seeding success. Watering should be done in frequent, light applications during the first 4 to 6 weeks to ensure good seed germination, emergence, and root development. The use of an organic mulch can reduce the potential fluctuations in surface soil moisture and soil temperature during this critical establishment period. New seedings without mulch may require light watering 2 to 3 times per day to maintain soil surface and seed moisture.

**Transplants:** Young transplants require frequent and regular watering until root development can provide the proper shoot to root ratio. Some woody species (oak in particular) spend several years developing an extensive root system before a corresponding increase in above-ground development is realized.

**Established Plantings:** There are two times during the year when it is critical that the rooting zone of a plant be at or near field capacity—fall and early spring. Fall moisture is essential for the health and vigor of plants for winter survival. Evergreens, in particular, should be deep watered in late fall to prepare for possible warm periods during the winter months. As temperatures rise in the spring, water is needed to support rapid early growth.

Water is wasted when applied too heavily or rapidly. Excessive slope and poor location for turf area contribute to runoff.

Low pressure sprinkler systems conserve water by delivering small amounts exactly where needed.

Other Considerations

- South and west exposures require more frequent watering than north or east exposures.
- Sloping landscapes require water to be applied more slowly than flat surfaces to allow adequate infiltration and prevent runoff.
- Berms or terraces hold water and stabilize severe slopes.
- Avoid using sprinklers that throw a fine mist high in the air.
- Avoid watering during hot, windy, or rainy weather.
- Design plantings and structures to capture snow for additional moisture.
**Water Conservation Strategies**

### Zoning

Plants should be established in zones to maximize water use efficiency. These zones dictate the best irrigation system to be used, e.g., underground sprinkler (high watering zones), drip/trickle (moderate watering zones), or conventional hose (low watering zones).

<table>
<thead>
<tr>
<th>High Watering Zones</th>
<th>Moderate Watering Zones</th>
<th>Low Watering Zones</th>
</tr>
</thead>
<tbody>
<tr>
<td>20 gals. added per sq. ft. per growing season</td>
<td>10 gals. added per sq. ft. per growing season</td>
<td>2 to 3 gals. added per sq. ft. per growing season</td>
</tr>
<tr>
<td>½ inch 3 times/week</td>
<td>¼ inch once/week</td>
<td>½ inch every two weeks</td>
</tr>
<tr>
<td>Approx. 30 inches added/season</td>
<td>Approx. 16 inches added/season</td>
<td>Approx. 5 inches added/season</td>
</tr>
</tbody>
</table>

### Shading/Shielding

Plants that have high moisture requirements or prefer shade can be located beneath or on the shady side of larger plants, fences, or buildings. Afternoon sunlight is more intense, so plants to be shaded should be put on the easterly side of large plants or structures.

### Mulching/Landscape Fabric

Mulches are used to minimize evaporation, and reduce weed growth and erosion. Apply mulch directly to the soil surface or over landscape fabric. Don’t use black plastic unless it’s been perforated; it prevents air and water from reaching plant roots and reduces beneficial soil organisms.

**Organic** mulches such as wood chips, peat moss, sphagnum moss, or grass clippings decompose and improve soil texture, but must be replenished periodically. Apply in a layer 2 to 3 inches deep between plants.

**Inorganic** mulches such as rocks or gravel rarely need replacement and are good in windy areas. Apply in a layer 2 to 4 inches deep between plants. This usually works best if installed on top of landscape fabric.

**Newly seeded areas** can be mulched with weed-free hay, straw, or composted grass clippings. This will help retain soil moisture, increase site stability (reduce soil and water erosion), and provide more uniform heat at the time of seed germination. Apply mulch in a layer no more than 1/2 inch deep over the seeded area.

### Root Lengths Vary

Root depth is proportional to top growth. There are exceptions: grass roots can be shallow or very deep; bulb roots are short compared to their top growth.

Tree roots spread from the trunk for a distance equal to or greater than the height of the tree. 75 percent or more of the roots are within the top 12 inches of soil.

### How Much/How Often

The amount of supplemental water applied and the duration of each application depends on several factors:
- amount and type of plant cover
- amount of organic matter
- type of soil (infiltration rate)
- water application method
- soil compaction (bulk density)
- time of day
- weather (evapo-transpiration)
- slope (runoff potential)

### Infiltration Rates and Available Soil Water by Soil Texture

<table>
<thead>
<tr>
<th>Soil Texture</th>
<th>Infiltration Rate (inches per hour)</th>
<th>Available Water per Foot of Soil</th>
</tr>
</thead>
<tbody>
<tr>
<td>Vegetated</td>
<td>Sand, 1.2; Silty, 1.0; Loamy, 0.5</td>
<td>Sandy, 0.5; Silty, 1.0; Loamy, 2.5</td>
</tr>
<tr>
<td>Bare</td>
<td>Clay, 2.00</td>
<td>Sandy, 0.5; Silty, 1.0; Loamy, 2.5</td>
</tr>
</tbody>
</table>

The frequency of irrigation is dependent primarily on the moisture requirements of the plants and the water-holding capacity of the soil. Plants should be carefully monitored for signs of moisture stress, i.e., loss of leaf turgidity (drooping), curling of leaf edges, and leaf discoloration.

### Drip Emitters

The most efficient use of water is the slow, deliberate metering of water directly to individual plants. Drip systems can be installed underground or laid across the soil surface. Most drip systems work with low pressure and often require a filtration system to prevent the clogging of emitters. Drip systems must be monitored to avoid over saturation below the soil surface.

**Soaker hoses** deliver water slowly and with very little loss to evaporation.
Pruning is usually done on woody plants, but can also refer to the removal of seedheads and other mature plant parts from herbaceous plants.

**Herbaceous Plants**
Maturing seedheads can be pruned to stimulate secondary flowering or prolong vegetative growth later in the growing season. Herbaceous material should be trimmed and removed in late fall or early winter. Mature specimen plants can be left to add winter color or aid in trapping snow. Herbaceous specimen plants left standing over winter should be trimmed in early spring to remove dead plant material and unwanted plant litter.

**Woody Plants**
Woody plants should be pruned at an early age to conform with the intended use and landscape design. Trim to a single stem or leave as multi-stem plant.

- Prune lower branches to provide lower stem sanitation or alleviate shading of adjacent groundcover plants.
- Prune disease and insect-affected plant parts to minimize spread.
- Remove rubbing, deformed, or dead branches at any time.
- Prune interior limbs to reduce wind resistance.
- Conifers should be pruned in spring or early summer. They are usually pruned to correct deformities.
- Deciduous trees and shrubs should be dormant-pruned in late fall or winter.

**Using Chemicals**
- Follow the label for proper pesticide application rates and target species. For insect and disease damage it is important to properly identify the insect or pathogen before attempting any control measures.
- Avoid leaving a stub. Remove the entire limb, cutting close to the branch collar of the trunk or branch from which it is removed. Do not cut into the branch collar (flush cut).
- Use sharp, high-quality pruners. Note: sterilize pruners with 10 percent bleach solution after cutting diseased branches.

**TIP:**
Prescribed burning can be an effective tool for maintaining native landscapes. Always check local regulations and work with experienced personnel.

Living Landscapes in South Dakota: A GUIDE TO NATIVE PLANTSCAPING
Mowing
When mowing, leave at least a 3-inch stubble height. With taller-statured grasses, an even higher stubble height should remain. Various grass species respond differently to mowing. Rhizomatous species are stimulated by frequent clipping while bunchgrasses are often stressed or even eliminated by frequent cutting.

Mowing frequency and intensity will vary according to the species and intended use of a particular stand of grass.

- **Manicured Lawn**
  Maintain at uniform height. Most sod-forming species are naturally short-statured.

- **Biomass Removal**
  Consider removal of dormant or dead stems and leaves at the end of a growing season for fire prevention and reduction of potential snow drifting.

- **Weed Control**
  Mowing, especially during the establishment year, can help with weed control by not allowing annual weeds to set seed.

Fire can be used as a substitute for mowing to reduce biomass when the grasses are dormant, i.e., late fall or early spring. Mature warm-season grasses, in particular, benefit from the removal of biomass, which stimulates the next year’s growth. Avoid property damage and annoyance to neighbors. Burning permits may be required — inquire locally.

Fertilizer
Most arid and semiarid native plants do not need supplemental fertilization if established on natural soil conditions. If subsoil is exposed or the soil is extremely sandy, fertilization may be warranted. Excess fertilization will increase biomass production, thus increasing soil moisture requirements for the plants.

- **N-P-K**
  - Nitrogen (N) for leaves
  - Phosphorus (P) for roots
  - Potassium (K) for blossoms

New Seedlings
Unless you are planting into a very raw mineral soil, fertilizers (particularly nitrogen) should not be applied the seeding year—as you would only be feeding the weeds rather than the seeded plant material. Incorporation of supplemental phosphorus when preparing the seedbed helps promote root development.

Established Plant Material
Grasses: Apply in the fall (early to mid-September) to promote winter survival and early spring growth.

Wildflowers: Use very low rates, if any at all. High fertility levels will stimulate spindly and weak stem growth.

Trees and Shrubs: Apply macronutrients (N-P-K) early in the growing season. Late summer application could delay proper “hardening off.” Micronutrients are available in foliar spray. Since safe limits for application rates of trace elements are narrow, they are best applied with caution. High and low soil pH can limit essential micronutrient availability to plants.

Pest Control
Adopt an Integrated Pest Management (IPM) approach to controlling weeds, insects, and disease. This approach incorporates monitoring to determine the level of infestation with a combination of control measures, i.e., cultural practices, pesticides, biological control, choosing plants with pest and disease resistance, maintaining good plant health (vigor), practicing good sanitation, and properly timed control methods. Cultural practices include tillage, hand-pulling of weeds or hand-plucking of insects, and mowing.

Insects
Native vegetation often attracts desirable insects rather than pests. Butterflies and other pollinators will be attracted by flowering forbs and shrubs. Conscientious use of pesticides, use of less toxic compounds (insecticidal soap, dormant oil spray, diatomaceous earth), and strategic placement of insect-deterring plants should control most insect pest problems. Monitor insect populations closely and apply control measures in the early stages of infestation.

Diseases
Sanitation is key to disease control and prevention. Most diseases can be avoided by carefully monitoring the plants. Native plants have a natural immunity to many diseases. Selective pruning, excess litter removal, and in some cases, by using fire, diseases in a natural landscape will be minimal. Avoid late afternoon or evening watering.

Animals
Native landscaping, especially in rural and suburban areas, will attract potentially damaging animals (deer, rabbits, rodents, beavers). Until plants are large enough to withstand browsing, some form of plant protection may be necessary (see Plant Protection section). The planting of less palatable shrubs and trees is a feasible alternative.

Weeds
Perennial weeds should be addressed prior to implementation of a landscape plan. Annual weeds can be reduced by keeping them from going to seed. The first two establishment years require the most maintenance, but once landscape plants are established, maintenance becomes easier and more routine. Caution should be used when using any herbicides within the rooting zone of woody plants.

Caution: Overuse of fertilizers may result in the contamination of surface and ground water, and the unwise use of natural resources. Utilize a soil analysis to identify soil nutrient deficiencies and fertilize accordingly.
Protection is the preventative maintenance of plant care. Although it is often thought of in terms of avoiding damage from animals or people, protection includes any proactive steps to minimize plant stress and maintain health. An important step in this process is selecting well-adapted species and maintaining them in a vigorous condition.

### Protecting Plants from Desiccation

Desiccation occurs when water loss from the plant (transpiration) exceeds its ability to extract water from the soil. Numerous factors contribute to desiccation including temperature, wind speed, sun exposure, soil texture, available soil moisture, and stage of plant growth.

- Cease weed control in and around trees and shrubs in mid to late August, letting the herbaceous weeds grow tall to trap snow and increase available water to the plant. Deep snow pack protects young trees and shrubs from drying winds and animal browse.
- Water in anticipation of high plant demands throughout the growing season.
- If the soil is dry in late August to the first week of September, saturate the top foot of soil to reduce winter dessication.
- Use anti-desiccant spray on green foliage to reduce water loss from leaves immediately after transplanting. This is also beneficial to conifers when applied just before freeze-up.
- Install wood mulch or weed control fabric to conserve soil moisture.
- Use shingles or screens on the west and south sides of newly planted seedlings to reduce wind desiccation and sun exposure.
- Install manufactured tree shelters to protect from sun and wind, and to encourage rapid growth and establishment.

### Protecting Plants from People

People often injure landscape plants through neglect, carelessness, or misguided effort. Protection from people includes proper landscape design, appropriate species selection, proper planting location, installation of physical barriers, the use of warning signs, and proper education.
# Strategies for Protection from People

<table>
<thead>
<tr>
<th>Common People Problems</th>
<th>Protective Measures</th>
</tr>
</thead>
</table>
| Mower and weed trimmer injury to trees and shrubs | • install synthetic wrap around base of trunk  
• install weed barrier or mulch around base of tree  
• install ornamental fence  
• plant flowers or ground cover around base of tree |
| Heavy traffic | • install physical barrier, (man-made or plants) to reduce traffic;  
• construct a sidewalk or path  
• construct a fence or wall  
• install warning signs (commercial) |
| Misapplied chemicals and fertilizers | • apply pesticides only when absolutely necessary  
• always follow label instructions  
• base fertilizer applications on soil test results (if some is good, more is not necessarily better)  
• consult with a professional |
| Improper mowing | • mowing too low is often a problem; raise mowing height to 3 inches  
• keep blades sharp to prevent tearing |
| Improper pruning | • learn proper pruning techniques  
• use sharp, high-quality pruners  
• if unsure, hire a professional |

---

# Protecting Plants from Animals

Ornamental landscapes attract and provide habitat for numerous animals including deer, rabbits, gophers, mice, and other wildlife. Although some designs intentionally incorporate features to attract wildlife, damage to landscape plants can be serious and may warrant the need for protection. The type and cost of protection varies with the value of the plants and the potential for damage.

**Repellents.** Repellents are products that, when applied to the plant or soil, discourage animals from feeding on or otherwise damaging the plant. They are:
- Usually low-cost products
- Well suited for use in gardens, orchards, nurseries, and ornamental landscapes
- Generally, only effective for a short period of time and require multiple applications in order to continue providing protection
- Increasingly ineffective as browse and forage become limited

**Exclusion.** In general, exclusion systems provide more absolute protection than other techniques. These barriers may be physical and/or electrical in mode of action. Physical barriers include wire cylinders and cages, ventilated plastic tubing, netting, wraps, fences, screens, and hardware cloth.

Livestock damage

**Cultural.** Cultural practices such as weed control, brush management, pruning, and mowing can be used to reduce cover in the vicinity of the target plant. Remove tall, dense herbaceous vegetation from around trees and shrubs to discourage rodents.

**Plant Selection.** Browsing damage can sometimes be reduced by selecting plants that are not preferred by wildlife and livestock. Keep in mind that starving animals will utilize nearly all edible vegetation.

**Using Domestic Animals for Plant Protection.** Secured dogs and other domestic animals are sometimes effective in scaring away unwanted wildlife. New designs that incorporate wireless fences have proven effective in the nursery industry.

**Animal Removal.** In some cases, it may be necessary to relocate damaging animals. Contact your county animal control department.

**Sacrificial Crops.** Highly palatable, low-cost crops can sometimes be used to lure wildlife away from landscape plants. Caution should be used when designing such systems to avoid attracting additional animals into the area. This is best suited to farm or ranch situations.
Properly planned native landscapes can provide wildlife with various habitat needs. Selecting plants that provide food, cover, and water to landscapes can provide the needed habitat elements for many species that will visit your backyard.

During the planning process wildlife habitat requirements need to be considered. Wildlife needs vary from year-round habitat for resident species to seasonal habitat for migratory species. Various types of wildlife species will visit if their habitat requirements are provided.

The types of plants used to provide food and cover will determine the wildlife species that are attracted. Select native species that flower and bear fruit or seed at different times during the short Northern Plains growing season. Plant a variety of species including grasses, flowering forbs, shrubs, and trees. Shrubs that hold their fruit into fall and winter can provide food well into the winter season. Native forbs will attract butterflies.

A variety of herbaceous and woody plant materials will provide a diversity of structure for wildlife cover. Depending on the species selected, these same plants can provide cover and a food source into fall and winter. Plant in groups or clusters. Single plants of native grass, forbs, or shrubs will not provide the habitat needed for wildlife. Larger groups of shrubs, grass, or flowering forbs provide increased diversity, cover, and food in close proximity and structural heights attractive to wildlife.
Considerations

Food
Learn the food needs of the species you wish to attract and plant accordingly. Provide plant species that will yield a variety of foods during the year. If you wish to attract birds, plant species that retain fruit into the winter season, such as junipers, highbush cranberry, native rose species, or species that will retain seeds into the winter such as Maximilian sunflower. Native grasses also provide seeds for birds. A variety of flowering forbs attract insects and will attract birds that feed on those insects. Hummingbirds can be attracted by planting flowers with high nectar levels. Butterflies seem more attracted to purple and white flowers than yellow.

Water
Wildlife needs may vary. However, they all need water to survive. Some species utilize dew on plants while other species need open water. Plan for water in your backyard. If natural water is available, protect it from sedimentation and nutrient loading with grass buffers. Artificial water can be added by use of bird baths, lined ponds, or construction of a clay-lined created wetland. Year-round water is important. A heated water source can attract birds to backyards. Keep water fresh, and provide logs or rocks as escape areas around deep water sources for birds and maybe even a basking turtle. Small depressions in rocks can collect water and attract butterflies.

Cover
Wildlife species need multiple cover types located close to food to avoid predation and exposure to harsh winter elements. The type of wildlife you wish to attract will dictate the required type of covers planted. Planting native grasses and forbs will attract birds that nest on the ground and feed on small seeds and insects. Planting a variety of trees and shrubs will attract bird species that nest in woody vegetation and use fruits or nuts as food sources. Cover must be close enough to food to provide safe access for wildlife. Cover types that provide an array of vertical structure will attract a wider variety of wildlife species.

Management of cover is a key component to attract wildlife. If native grasses and forbs are mowed during the primary nesting season, nesting cover is destroyed. Leave residual cover into winter to provide adequate nesting cover in spring. To provide nesting cover, native grasses should not be mowed during the nesting season from mid-April to late July and should only be mowed periodically (once every 3 to 5 years) to provide the residual cover needed for ground or grass nesting birds.

For information on backyard landscaping for wildlife consult this publication from the Natural Resources Conservation Service:

Backyard Conservation

“Backyard Conservation” can be ordered by contacting the Natural Resources Conservation Service Landcare Office at http://landcare.nrcs.usda.gov or call 1-888-LANDCARE (526-3227).

For more information on backyard landscaping and habitat for wildlife go to http://www.nrcs.usda.gov/feature/backyard/.
Rain gardens are shallow depressions that collect storm water from impervious surfaces (roofs and driveways) and infiltrate, filter, evaporate, and transpire the runoff. Rain gardens are typically planted with a diverse mix of native wildflowers, grasses, shrubs, and trees, and are an attractive low-maintenance addition to a home landscape. For much of South Dakota, water captured by a rain garden is much better quality than water that comes from a typical well, and considerably cheaper than water available from urban or rural water systems.

Planning

• Map the property. Note topography, buildings, existing vegetation, underground utilities, and other features. Determine where existing runoff flows.
• Calculate the area of all runoff surfaces that will collect in the rain garden.
• Locate garden in an area that captures the most runoff and requires the least amount of digging and diking to get level. Stay at least 15 feet away from structures and poured slabs and 50 feet away from septic leach fields.
• Make the rain garden about 10 percent the size of the area contributing water and 6 to 9 inches deep. (6-inch depth will capture 0.6 inches of runoff and 9-inch depth will capture 0.9 inches runoff.)
• Direct runoff to the rain garden with drain tile or a constructed swale, if needed.
• Plan for a controlled overflow to prevent erosion from large runoff events, especially during the first year or two before berms are fully sodded and vegetation is well established.
• Choose a variety of native perennials adapted to the soil and light conditions. Include at least 40 percent grasses and sedges to provide dense root masses, interesting textures and support for flower stems.

Rain gardens should have standing water for no longer than 24 to 48 hours. Mosquitoes generally take 7 to 10 days to complete their breeding cycle, so rain gardens should not increase mosquito populations.
Construction

- Remove existing vegetation by tillage, covering with black plastic for several months, or using a herbicide such as glyphosate.
- Dig a shallow bowl (6 to 9 inches deep at the center) with gently sloping sides.
- If clay or heavy soils are present, over excavate the site by 1 foot and backfill with a mixture of 70 percent washed sand and 30 percent compost blended together.
- Place excavated soil on the downhill side to create a berm that ensures water will be a uniform depth within the basin. Part of the berm should be slightly lower than the inlet to allow for controlled overflow from extreme runoff events.
- Ensure that the top of the berm is perfectly level to reduce the chances of erosion damage.
- After seeding and planting the berm, cover with biodegradable erosion control blanket to hold soil in place while plants become established.
- Spread 2 to 4 inches of shredded wood mulch over the entire planting area. Ordinary wood chips tend to float and should be avoided.

Planting

- Rooted stock and seeds can be planted from early May until the end of June.
- Plant seedlings 12 inches apart, with more flood tolerant species toward the bottom and drought tolerant species toward the top.
- Plant species in large clusters to provide more visual impact.

Maintenance

- Rain gardens will require maintenance each year, a bit more the first two years.
- Ensure the rain garden receives at least 1 inch of water per week for the first 2 months from irrigation or rain.
- Control weeds. Placing plant tags near each plant or using a plant ID book will aid in determining which are weeds.
- Many native species have strong stems and will stay standing even after a snowfall. Allow the year’s growth to stand over winter, providing visual interest, wildlife habitat, and good quality water harvested from snow.

Landscaping to Save Energy

Saving money is an obvious reason for landscaping choices that reduce fossil fuel use. Reduced fossil fuel use is environmentally friendly. Landscaping to save energy can benefit wildlife and conserve water. Beauty can be maintained or improved with landscaping that saves energy.

Goals for energy-efficient landscaping are reduce heat, air conditioning, and maintenance requirements.

**Landscape for Heating Efficiency**

Tree/shrub windbreaks can dramatically reduce the chilling effect of winter winds. Home heating costs can be cut as much as 30 percent with properly designed windbreaks. Optimum wind protection is downwind from the trees at a distance of 4 to 7 times the height of the trees. Optimum windbreak density of 60 percent is typically achieved with one row of spruce or juniper, two rows of pine, or six rows of deciduous trees. A site-specific windbreak design is essential to ensure that the location, species selection and arrangement, and maintenance plan are compatible with the soil and the landowner’s preferences.

Trees for shade and scenery are usually planted closer to houses and other buildings than are windbreaks. Deciduous trees close to the house let sunlight pass through the crown after the leaves drop, assisting with winter solar gain. Shrubs planted 3 to 5 feet from the north or west side of a house can reduce radiant and convective heat loss. They must be pruned regularly to prevent branches from rubbing and damaging the siding or roof.
Energy Conservation

Landscape for Cooling Efficiency

Trees and shrubs can provide valuable shade to a house, reducing energy consumed for air conditioning. A shaded roof reduces house temperature as much as 10 degrees. Tall, deciduous trees are preferred for roof shade. Their structure provides shade in summer but lets sunlight through in winter. Optimum distance from tall shade trees to a building is 15 to 20 feet. Sturdy species such as bur oak, hackberry, or green ash are preferred to reduce the risk of broken limbs damaging the building. Proper pruning as the trees grow is crucial for strong limbs and trunks, and prevents rubbing damage to the siding or roof. Instructions are found in the NDSU Extension Service Bulletin “Pruning Trees and Shrubs” at http://www.ext.nodak.edu/extpubs/plantsci/trees/h1036w.htm.

Tall trees planted on the east side and southeast corner intercept the morning sun, significantly slowing the warm-up process in the summer. Tall trees on the south side block valuable sunlight in winter. Tall trees on the west side and southwest corner provide valuable shade from the summer sun on hot afternoons and evenings.

Shrubs planted close to the house on the west and east sides can intercept or deflect solar heat, reducing interior temperature. Choose species that are adapted for the space and size of the wall to be screened. Where rubbing damage could occur, plant shrubs far enough away from the house or prune them as needed.

Vines can also be grown near or on buildings to intercept solar heat. Selecting a species with desired traits is important. Not all vine species are capable of climbing bare walls. Riverbank grape is a native vine that will produce edible fruit if pruned annually. It is not adapted to climb a bare wall but is suited to a trellis. Woodbine is another native vine that is well suited to intercept solar heat. If you find vines visually appealing, they may have a niche in your landscape. Information about different vine species is available from the NDSU Extension Service, http://www.ext.nodak.edu/county/cass/horticulture/treeshrub/vines.htm.

Air conditioners and heat pumps will consume less energy if they are shaded. A tall shrub or vine-covered arbor can provide shade and attractively screen such equipment. Leave at least 5 feet of clear space around air conditioners and heat pumps for air circulation and maintenance. Place the plant so that at maturity it will shade the air conditioner or heat pump when the appliance is running.

Landscape to Minimize Maintenance

Lawn mowing burns 800 million gallons of gasoline annually in the USA. About 90 million pounds of pesticides are put on lawns and gardens annually. Irrigating a 75 x 100 square-foot lawn with ¾ inch of water twice a week for eight weeks demands pumping and paying for 56,000 gallons of water. Substantial amounts of chemicals and energy are used to treat and pump municipal and rural water applied to lawns. Landscaping with native plants minimizes mowing, watering, fertilizing, and pesticide inputs.

Most lawns in South Dakota are Kentucky bluegrass. They are mowed frequently from May through September. They are regularly irrigated in western South Dakota, and commonly irrigated elsewhere in the state. Fertilizer and herbicides are often applied to this introduced species.

Blue grama and buffalograss are short, native perennial grasses, that are alternatives to Kentucky bluegrass for lawns. They are drought-tolerant, warm-season species that grow very little before June or after August. These short species require only 3 to 4 mowings per year and no fertilizer. Irrigation may be required for establishment. Established stands do not require irrigation and spring or fall watering may encourage weed growth. During drought and periods of dormancy, these species turn a tan color.

Buffalograss prefers clay to loamy soil, while blue grama is adapted to soils ranging from sand to clay. They look alike and can be grown alone or together. Planted as a mixture, blue grama and buffalograss have a uniform appearance.

One plan would be to plant Kentucky bluegrass next to the house and native species on the remainder. A strip of native flowers can attractively separate the Kentucky bluegrass from the low-maintenance blue grama/buffalograss area.

Irrigation costs can be reduced by piping or channeling roof runoff toward trees, a rain garden, or native flowerbeds. The runoff from some driveways can likewise be diverted to enhance plant growth and vigor.

Mulch can be used for saving water, labor, and energy. Wood chips, leaves, grass clippings, or other organic matter around trees, shrubs, and flowers lower soil temperature and reduce evaporation. A layer of mulch 2 to 3 inches thick will usually control weeds. Mulch materials can often be obtained free from a city maintenance department, neighbors, or utility company. More information about mulching is available at http://www.nrcs.usda.gov/feature/backyard/Mulching.html.

Snow is an important consideration in landscaping. Windbreaks, yard trees, and shrubs will reduce snowblower work and fuel consumption if correctly placed. Spruce and juniper trees with low-level branches intact provide maximum density and trap snow in the shortest, deepest drifts. Deciduous trees with the lower branches removed yield the longest drifts. Multiple tree rows increase density and shorten snow drifts.
Weeds and Invasive Plants

Weeds are often defined as “plants out of place.” An attractive wildflower to one individual may be an aggressive, spreading weed threatening to take over flowerbeds to another individual.

Noxious weeds are designated by state government and control is required in any setting by county, state or federal law. Distribution of these weeds by any means is not allowed. The uncontrolled spread of noxious weeds can have dramatic impact on local agriculture. Nearly 4.5 million acres are infested. Statewide losses from noxious weeds exceed $80 million annually.

Invasive plants can be native or introduced species: 1) that are non-native (or alien) to the ecosystem under consideration and, 2) whose introduction causes or is likely to cause economic or environmental harm or harm to human health. The State of South Dakota has no legal authority regarding invasive plants. Legal parameters and policies regarding invasive plants vary widely among units of government.

Noxious Weed Characteristics

A weed must possess the following characteristics to be declared noxious statewide:
• The weed is perennial.
• The weed has unique capability to spread rapidly.
• The weed is not controllable without special prevention or management.
• The weed is capable of decreasing the value of land.
• The weed is capable of materially reducing the production of crops or livestock.
• The weed is not native to South Dakota.

It is up to the landowner/homeowner to be aware of plants that may cause potential problems. The extent of the invasiveness, especially for native species, may be subjective and vary widely depending on site and associated species in the plant community.

Common forage and turf grass species such as smooth bromegrass and Kentucky bluegrass become invasive on many sites managed for native plant communities. There are many important conservation tree and shrub species that can easily move offsite and become invasive. Russian olive is a good example and should not be planted in wet sites, riparian areas, or saline lowlands where it may move offsite and cause environmental or economic problems.
Noxious weeds currently listed by the South Dakota Department of Agriculture as noxious state-wide include: Canada thistle, leafy spurge, perennial sow thistle, hoary cress, Russian knapweed, purple loosestrife, and saltcedar.

Others listed as local noxious weeds include musk thistle, plumeless thistle, bull thistle, scotch thistle, absinth wormwood, dalmation toadflax, yellow toadflax, houndstongue, spotted knapweed, diffuse knapweed, tansy, St. Johnswort, puncturevine, mullein, burdock, giant knotweed, chicory, and poison hemlock.

For scientific names, pictures, and specific control information, go to http://www.state.sd.us/doa/das/noxious.htm#weed. For more information, check out SDSU Cooperative Extension Service publication “Noxious Weeds of South Dakota” (Extension Special Series 34) at http://agbiopubs.sdstate.edu/articles/ESS34.pdf
Traditionally, native plants were integrated into every facet of daily living: used for adornments, basketry, building materials, ceremonial events, clothing, cordage, cosmetics, dyes, foods, games, household utensils, medicines, musical instruments, poisons, tools, toys, transportation, and weapons. Plants were gathered throughout South Dakota and all vascular life forms were used, from herbs, to grasses, sedges, shrubs, trees, and vines. The vegetation was the grocery store, the pharmacy, and the hardware shop, tailored by each cultural group into its own unique ethnobotany.

The collective wisdom about how to tend, judiciously harvest, and use native plants has evolved over thousands of years and gives us models of human intervention in nature that demonstrate a common ground between the conservation and utilization of plants. Often, hidden within the simple act of gathering frequently lie complex rules that safeguard the plant stock from being over-harvested. Also, the procurement of different plants can be spiritually significant and/or a ceremonial act because for many native peoples, the physical, spiritual, and ceremonial uses of plants are inter-related.

(NRCS Plant Material Center)

Referred collectively by outsiders as Sioux, the Sioux call themselves Lakota, Nakota, or Dakota, depending on dialect, which means “friends or allies.” The Sioux had substantial knowledge about their environment, particularly about the use of plants and herbs which grew in their surroundings. The uses to which these plants and herbs were many and varied. For instance, Sioux women still collect edible plants and fruits such as prairie turnips (Psoralea esculenta), chokecherries (Prunus virginiana), and wild plums (Prunus americana). Plants such as sweetgrass (Hierochloe hirta and Hierochloe odorata) and sage (Artemisia ludoviciana), are still collected and used for ceremonial purposes. A large range of traditional medicinal plants like the prairie cone flower (Echinacea purpurea and Echinacea angustifolia), also known as echinacea, the root of sweet flag (Acorus calamus L.), and yarrow (Achillea millefolium) are also still used today.

CULTURALLY SIGNIFICANT NATIVE PLANTS

*Ethnobotany is the study of how different cultures (usually indigenous groups) use, manage, and generally interact with plants. Major topics include ways that different cultures perceive, classify, and evaluate plant species and ways that cultures enhance native plant populations for their own needs using such techniques as pruning, burning, sowing, weeding, and coppicing.

Sweetgrass and Sage are still collected and used for ceremonial purposes.

C. 1920 Photograph of a Lakota woman holding a string of wild turnips and a bag of what appears to be the same. Turnips were typically dug, the rind removed, braided and hung in the sun or placed in the smoke of fire to dry. They can be pounded into a powder to thicken a soup, boiled with meat, or simply roasted and eaten. Ethnographic sources indicate that plant tops were left in the field when the turnip roots were harvested in order to rejuvenate the population and were harvested when seeds were ripening.
c. 1925 Photograph of a Lakota woman preparing chokecherry patties. The pulp and kernels of the fruit were ground together; patties formed and laid out to dry. Chokecherries can be used to make wojopi, a traditional pudding; dried chokecherry patties used to make the ceremonial food, wasna; cherry juice for Sun Dances; and jam for toast and biscuits.

Wild Plums and Chokecherry were among the many wild species gathered as a food source.

Traditional medicinal plants like the prairie cone flower (also called echinacea) and yarrow are still in use today. As populations of useful native plant species continue to dwindle on tribal and public lands, there is increasing need expressed by Native Americans to the NRCS Plant Material Centers (PMC) and field offices to assist them in the re-establishment of culturally significant plants in various landscapes. Ethnobotanical projects involve increasing partnerships between NRCS offices, Native American tribes, public land agencies, and private landowners. NRCS Plant Material Specialists in different parts of the country have begun using their skills to assist tribes in propagating, out-planting, and managing populations of culturally significant plant species in reservation and rancheria settings. Native plants are still vitally important to Native Americans to continue their traditions of basketry, ceremonies, preparing traditional foods, and other customs. (NRCS Plant Material Center)

For more information on culturally significant plants go to http://plants.usda.gov/culturalinfo.html
FIREWISE LANDSCAPING

About Firewise

The national Firewise Communities program is a multi-agency effort designed to reach beyond the fire service by involving homeowners, community leaders, planners, developers, and others in the effort to protect people, property, and natural resources from the risk of wildland fire - before a fire starts. The Firewise Communities approach emphasizes community responsibility for planning in the design of a safe community as well as effective emergency response, and individual responsibility for safer home construction and design, landscaping, and maintenance.

The national Firewise Communities program is intended to serve as a resource for agencies, tribes, organizations, fire departments, and communities across the U.S. who are working toward a common goal: reduce loss of lives, property, and resources to wildland fire by building and maintaining communities in a way that is compatible with our natural surroundings.

Editor’s note: These two pages contain a summary of Firewise Landscaping steps and tips, and is intended to serve only as a guide. For more in-depth information about protecting your home and land from wildfire check out these websites: South Dakota Wildland Fire Suppression at www.state.sd.us/doa/wfs/urbaninterface.htm; Keep South Dakota Green Association at www.state.sd.us/doa/fire/sd_green_association.htm; USDA Forest Service/Black Hills National Forest at www.fs.fed.us/r2/blackhills/; National Interagency Fire Center at www.nifc.gov; FIREWISE at www.ewise.org.
To create a landscape that will make your home less vulnerable to wildfire, the primary goal is fuel reduction. Think of the area around your home in zones. Zone 1 is closest to the structure, Zone 4 is the farthest away.

Zone 1: This well-irrigated area encircles the structure for at least 30 feet on all sides, providing space for fire suppression equipment in the event of an emergency. Plants should be limited to carefully spaced fire resistant tree and shrub species.

Zone 2: Fire resistant plant materials should be used here. Plants should be low-growing, and the irrigation system should extend into this section.

Zone 3: Place low-growing plants and well spaced trees in this area, remembering to keep the volume of vegetation (fuel) low.

Zone 4: This furthest zone from the structure is a natural area. Thin selectively here and remove highly flammable vegetation.

Also remember to:
- Carefully space the trees you plant.
- Take out the “ladder fuels” – vegetation that serves as a link between grass and tree tops. These fuels can carry fire from vegetation to a structure or from a structure to vegetation.

When maintaining a landscape:
- Keep trees and shrubs pruned. Prune all trees six to 10 feet from the ground.
- Water and maintain your lawn regularly.
- Mow dry grass and weeds. Dispose of cuttings and debris promptly. Landscape with less-flammable plants: Contact your local state forester, county extension office or landscape specialist for plant information.
- Thin tree and brush cover.
- Dispose of slash and debris left from thinning.
- Remove dead limbs, leaves and other litter.
- Maintain greenbelt, irrigate if needed.
- Mow dry grass and weeds.
- Stack firewood away from home.
- Reduce density of surrounding forest.
- Trim branches.
- Clean roof and gutters.
- Prune branches to 10 feet above ground.

South Dakota Department of Agriculture - Wildland Fire Suppression Division
Tree Care: Prune trees and non-flowering shrubs in late winter/early spring before they break dormancy. If needed, apply repellents and barriers (horticultural oils, “tanglefoot”) according to the label. Mulch out to the drip line.

Manicured Lawn Care: Apply pre-emergent herbicides in early spring, before weeds begin growth. Aerate, power rake, and fertilize lawns in May. Mow to no less than 2 ½ to 3-inch height to stimulate good root development. De-thatch if thatch accumulation exceeds ½ inch.

Warm-Season Grass Ground Cover: Mow to a 3-inch height and remove residue if necessary. Controlled burning may be an option if site, conditions, and ordinances allow. You may spot treat cool-season grasses and weeds with glyphosate herbicide, only if warm-season grasses are still dormant (not green, generally done in April). Ground covers are generally not fertilized.

Cool-Season Grass Ground Cover: Mow to 3-inch height. Consider appropriate herbicides, or hand dig troublesome weeds. Ground covers are generally not fertilized.

Prairie Planting: Before grasses have significant growth (April), cut to a 3 to 4-inch height and remove residue. Controlled burning may be an option if site, conditions, and ordinances allow. This would be a good time to add additional seed or plants to target areas, and to spot spray or remove perennial weeds, if desired.

Gardening: Start transplants indoors in late winter/early spring. Plant/transplant frost-tolerant plants, seeds, and seedlings in April-May; all others when the danger of frost is past (May-June). Divide and transplant fall-flowering perennials.

Compost vegetative trash to reduce volume and recycle nutrients back into the soil. Do not compost grass clippings that contain herbicide residues!

Pressurize and inspect all zones of an automatic watering system.
Summer...

1. **Watering**: Water plants in early morning, according to plant needs. Water deeply, uniformly, and infrequently, at a slow rate to reduce runoff potential. Do not over-water! Mulch where appropriate to reduce water consumption.

2. **Tree Care**: Prune spring-flowering shrubs just after blooms.

3. **Harmful Insects**: Control aphids and mites with insecticidal soaps to spare beneficial insects and provide long-term pest control. Do not use pesticides unless insect threshold levels warrant it.

4. **Weed Control**: Keep ahead of weeds by mowing and hand-pulling if possible. Use herbicides sparingly and according to label recommendations.

5. **Mulching**: Reduces water consumption, improves the soil structure and fertility, prevents weed growth, and protects against temperature extremes.

6. **Manicured Lawn Care**: Mow frequently. Remove no more than 1/3 of the leaf at one time. Set mower to 2 ½ to 3 inch height, and keep blades sharp! Mow higher during hot, dry spells to induce deeper rooting. Follow watering instructions above!

7. **Warm-Season or Cool-Season Grass Ground Cover**: Generally no watering is needed unless you want to extend the green period due to drought or species seasonality. Mow to suit your taste, generally once or twice on the warm season, and 3 or 4 times on the cool season, or forget mowing and enjoy the attractive seed stalks. The birds and butterflies will appreciate it.

8. **Prairie Planting**: Observe the natural beauty of species diversity; no mowing, or fertilizing, or watering to spoil the day! Consider keeping a notebook to record individual plant information such as: flowering dates, colors, number of blooms or seed stalks, pollinators attracted, favorite plants, seed or fruit ripening, and color changes. Occasional hand-weeding of unwanted plants is always timely. Take lots of pictures!

---

Fall...

1. **Manicured Lawn Care**: Fertilize around Labor Day. Sod or seed new lawns before September 10. If starting from seed, use hydro-mulch or a germination blanket to reduce weed competition and ensure good germination. Do not use straw.

2. **Prairie Planting**: Enjoy the fall colors which seem to change daily. Collect seed for future plantings. Leave the residue standing over winter and watch birds feeding on the seed, and the frost and snow adding their accents.

3. **Divide and transplant spring-flowering perennials. Dig bulbs for winter storage.**

4. **Watering**: Water landscape plants deeply before freeze-up for good establishment and winter survival. Mulch wherever possible to reduce water loss.

5. **Trees and shrubs**: Prune any damaged branches. Transplant new trees. Apply repellents and barriers to reduce animal damage. Mulch out to drip line.

6. **Weed control**: September is one of the best months to apply herbicides for controlling most persistent perennial weeds. Be careful to follow the label.

7. **Drain and blow out irrigation systems.**

8. **Provide snow fencing on windward side of landscape plantings for winter protection.**

Additional information on the above topics is also available from: Natural Resources Conservation Service, South Dakota Association of Conservation Districts, South Dakota State University Extension Service, and the South Dakota Resource Conservation and Forest Division.
